Paints and pigments: Manufacture of.—H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pat. 108,805. Jan. 11, 1917. (Appl. No. 596 of 1917.)

TITANIC oxide, a composite titanic oxide pigment, or a paint containing titanic oxide, is incorporated with a white mineral "extender substance," in the form of barytes, silica, gypsum, "asbestine," whiting, or china clay, the index of refraction of which is less than that of titanic oxide. (See also U.S. Pat. 1,223,357 of 1917; this J., 1917, 659).—B. N.

Pigment: Composite titanic oxide—and method of producing the same. I. E. Barton, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,236,655. Aug. 14, 1917. Date of appl., July 14, 1914.

A TITANIC compound is digested in sulphuric acid until titanic sulphate is formed, and calcium chloride is added in quantity insufficient to combine with all the sulphate in solution. The resulting precipitate is filtered off, the filtrate digested with barium chloride, and the precipitate of barium sulphate and titanic acid is separated, dried, and calcined. A soft, fine, white, amorphous powder, tinged with a cream colour, of sp. gr. 3.95 to 4.10, is obtained, containing not more than 0.5% of iron oxide, 85 to 89% of barium sulphate, and 11 to 15% of titanic oxide.—B. N.

Phenols, formaldehyde, and salts of sulpho-acids: Process for obtaining solid products of condensation from—K. Tarassoff, Moscow, and P. Shestakoff, Petrograd. U.S. Pat. 1,237,579. Aug. 21, 1917. Date of appl., Feb. 8, 1916.

SEE Eng. Pat. 102,635 of 1916; this J., 1917, 150.

Method of recovering resins from benzol-plant residues. U.S. Pat. 1,236,917. See III.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Resin, [mineral matter, and nitrogen] in raw rubber: Percentage of—Communication of the Netherlands Government Institute for advising the Rubber Trade and Industry. India-Rubber J., 1917, 54, 260—261.

THE apparatus used for the determination of the acetone extract or the "resinous matter" of rubber is a modified Berntrop extractor; in this the extraction thimble containing the finely divided rubber is suspended by two threads which are gripped between the cork and the mouth of a wide-necked flask, the thimble actually hanging in the boiling solvent for the first 2—3 hours, and then being raised so as to be thoroughly washed out for 1—2 hours longer by the acetone falling from the condenser. For the final removal of the acetone a glass tube is introduced into the flask in place of the paper cup. The results obtained by this method accord well with those yielded by the Soxhlet extractor; for 35 samples of plantation Hevea sheet the average percentage of "resin" was 2.89, an average of 2.88 being obtained with 102 samples of plantation Hevea crêpe, whilst with hard fine Para rubber the average is also near 3%. The observation of Hinrichsen and Marcusson (this J., 1910, 224) that the resins from *Hevea brasiliensis* rubbers are optically inactive whereas those from rubbers of other botanical origin possess optical activity, is confirmed; a difference between rubbers of various botanical origin also exists not only in the percentage of resinous matter but also in the extent to which these resins are saponifiable: thus

hard fine Para, Hevea sheet, Hevea crêpe, Castilloa, Congo, Jelutong, Dyera crêpe, and oxidised cut sheet rubbers yielded respectively 3.0, 1.8, 3.2, 18.9, 1.4, 38.1, 7.2, and 60.5% of resins, of which respectively 25.4, 48.3, 22.0, 73.7, 68.3, 83.2, 77.8, and 2.1% resisted saponification.

In comparative experiments on the extraction of balata with various solvents, higher yields of extractive matter were obtained with alcohol than with acetone; ether gave results generally exceeding those obtained with alcohol, and the addition of alcohol to the ethereal extract caused the formation of a white precipitate. Determinations of the proportion of constituents of balata insoluble in xylene indicated that these constituents coincide to some extent with those soluble in the above extraction solvents such as alcohol. With gutta-percha the alcoholic extract is lower than the acetone extract, and the conclusion is drawn that acetone is the most suitable solvent for the extraction of resins from balata and gutta-percha, the extraction being effected for three hours in the liquid and two above the liquid with the Berntrop apparatus.

The average ash for 35 samples of Hevea sheet was 0.38%, and that for 102 samples of Hevea crêpe 0.30%; individual figures may range from 0.15 to 0.65%; wild Para rubber yields approximately the same proportion of ash which, however, unlike the ash from plantation Hevea, always contains a fairly large amount of iron, the origin of which is uncertain. In Hevea rubbers produced by evaporation of the latex, the ash figure is higher, exceeding 1.5%, and reaches 1.2% or more even after the rubber has been washed. Bleaching with sodium bisulphite appears to be without influence on the ash content of plantation rubbers. In inferior qualities of plantation rubbers the yield of ash may exceed that stated above on account of the presence of sand, which may be detected in the ash by microscopical examination.

For the determination of nitrogen in rubber by the Kjeldahl process the acid used is a mixture of sulphuric acid (sp. gr. 1.84) and phosphorus pentoxide in the proportion of 1 litre to 200 grms.; 30 c.c. of this mixture together with one drop or 0.6 grm. of mercury are taken to 1 grm. of the rubber; the subsequent procedure is as usual, distillation of the ammonia being effected after the addition of caustic soda solution containing sodium sulphide. Applying the commonly accepted conversion factor 6.25, the average content of protein matter in Hevea sheet or crêpe was 2.82%. Rubbers produced by evaporation processes contain a higher proportion of protein, the values obtained ranging from 4.7 to 5.4%; Para rubber however generally gives results below 3% and sometimes even under 2%, so that either the Para process is not one of simple evaporation or the composition of Brazilian latex must differ from that of plantation latex. From the observation that nitrogenous matter is invariably found in the acetone extract, although to a varying extent with rubbers of different origin, it is probable that only part of the nitrogen present consists of protein. A small quantity of nitrogenous material is also removed on extracting rubber with water at 100° C.—D. F. T.

PATENTS.

Devulcanisation: Process of—D. Spence, Norwalk, Conn. U.S. Pat. 1,235,850. Aug. 7, 1917. Date of appl., June 27, 1914.

VULCANISED rubber in a finely divided condition or in solution in a suitable solvent, is treated with a substantial excess of a vulcanising accelerator together with a reagent adapted to combine with the sulphur liberated from the rubber; this reagent may be a part of the accelerator itself. D. F. T.

Vulcanised rubber; Process for removing the combined sulphur from — D. Spence, Norwalk, Conn. U.S. Pat. 1,235,852, Aug. 7, 1917. Date of appl., Dec. 20, 1916.

AFTER removal of the uncombined sulphur the vulcanised rubber is dissolved in xylene and subjected to the action of caustic alkali in a fine state of division in the absence of water. The solution is subsequently treated with acid and the rubber then precipitated from it. (See preceding abstract.) —D. F. T.

Plastic composition and process of making same, J. P. A. McCoy, Wilkesburg, Pa. Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,236,190, Aug. 7, 1917. Date of appl., Feb. 3, 1916.

PLASTIC compositions are prepared by heating a mixture of rubber or gutta-percha with a filler, and a resinous coal tar product containing cumarone, indene, para-cumarone, and para-indene, under reduced pressure until the material exhibits no substantial vapour pressure. —D. F. T.

Process for making [rubber] coated leather articles, U.S. Pat. 1,236,019. See XV.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin [extraction]; Effect of hard water on — T. A. Faust, J. Amer. Leather Chem. Assoc., 1917, 12, 360—374.

RESULTS obtained by several workers indicate that only slight losses in tannin occur when hard water is used for extraction. This does not agree with the work of Nihoul and Martinez (this J., 1901, 1905). It is suggested that temporary hardness is destroyed according to the amount of acid in the tanning material or extract, also that such hardness may have a solubilising action on tannins compensating for precipitation due to sulphates and chlorides. —F. C. T.

PATENTS.

Tanning of bulls or hides and apparatus therefor, J. E. Maude, Liverpool. Eng. Pat. 198,796, Dec. 9, 1916. (App. No. 17,732 of 1916.)

Two flexible chains, or like elements, are disposed round two series of pulleys, on opposite sides of a vat, in such a manner that each of the chains forms a polygon, one pair only of the opposite wheels in the series being sprocket wheels, and these are positively coupled together by bevel gearing, so that the two chains are kept accurately in step. The chain links are provided with apertured brackets, which serve to support removable rods, or perforated tubes, and ridge pieces are arranged near the path of the chains to prevent the rods from becoming disengaged. The hides are carried in sequence through the tanning liquor, and alternately immersed therein and lifted therefrom by means of the rods. —B. N.

Leather; Production of light coloured — S. Saxe, New York. U.S. Pat. 1,235,959, July 31, 1917. Date of appl., Aug. 11, 1915.

ALUMINIUM sulphate is added to the liquors in the later stages of tanning, to the extent of 5–10% of the vegetable tanning material employed. —F. C. T.

Fish skins or the like; Process for tanning — K. Bendixen, Copenhagen. U.S. Pat. 1,235,513, Aug. 7, 1917. Date of appl., Dec. 29, 1914.

Fish skins are treated with an alkaline solution to remove part of the oils or fats. The excess of alkali is then neutralised, and the skins washed with water. —F. C. T.

Leather articles; Process for making [rubber] coated — J. H. Butler, Assignor to F. W. Austin, Gloversville, N.Y. U.S. Pat. 1,236,049, Aug. 7, 1917. Date of appl., Oct. 22, 1914.

LEATHER is degreased on the surface, and treated with a solution of raw rubber. The solvent is then evaporated and sheets of raw rubber applied to cover the coated leather surface. The article is then heated to a vulcanising temperature, when the leather and rubber form a practically homogeneous fabric. —F. C. T.

Glue-like material; Process and apparatus for drying — L. Mooney, Searon, N.J. U.S. Pat. 1,235,716, Aug. 7, 1917. Date of appl., July 28, 1916.

LIQUID glue material is cooled and congealed in sheets on a corrugated cylinder, from which it is stripped and subsequently dried on drying conveyors. —F. C. T.

Method of deliming wool, hair, or like substances contaminated with lime, U.S. Pat. 1,235,214, See V.

XVI. SOILS; FERTILISERS.

Soils; Alkali —; some biochemical factors in their reclamation, J. H. Barnes and B. Ali, Agric. J. India, 1917, 12, 388—389.

AT Narwala in the Lyallpur district of the Punjab, the soil is barren owing to excess of salinity, the soluble salts present varying from about 0.5% to 4.4%. There is no toxicity in the salts themselves, which are chiefly sodium and calcium sulphates and chlorides and sodium carbonate. The barrenness is due to the osmotic pressure of the soil solution being greater than that of the cell sap of the plant, which causes the protoplasm to shrink from the walls of the cells and the plant to become flaccid. The osmotic pressure was measured indirectly by the activity of the bacteria in the soil, which is reduced by an increase of the osmotic pressure. The chemical changes which the bacteria produced in the soil were taken as a measure of their activity, and these were studied under three heads. (1) Carbon dioxide formation. The soil sample was placed in a Woulff's bottle and 1% of Indian colza, in the form of oil-free cake, and sufficient water to give 30% of saturation were added, and the bottle was incubated at 25–30°C. Each day the air contents of the bottle were removed by aspiration through baryta water and the amount of carbon dioxide absorbed determined. 200 grms. of normal soil gave by this method 684 mgrms. of carbon dioxide in 15 days, whereas the saline soil gave only 23 mgrms. When the saline soil was washed before testing, the amount of carbon dioxide formed was 839 mgrms. This showed how the reduction in the osmotic pressure in the soil solution caused by washing, enabled the bacteria present to develop and become active, and to produce even more carbon dioxide than the bacteria in a normal soil. (2) Nitrification. 50 c.c. of Omélsansky's solution was inoculated with 1 c.c. of 100% soil emulsion, 0.5 gm. of calcium carbonate was added, and the whole incubated at 30–35°C. The nitrite and nitrate contents were determined each week. Another form of this test was to add 1% of Indian colza to the soil, with water to 30% saturation, and to incubate at 30–35°C.; the ammonia, nitrite, and nitrate in the mixture were determined. The results in Omélsansky's solution were the production in 5 weeks of 1.2 mgrms. of nitric nitrogen from the saline soil, 1.8 mgrms. from a sterile patch, and 6 mgrms. from normal soil. In the sterile patches, the

salinity was less than in the general barren soil, but the osmotic pressure was not sufficient to destroy the activity of the nitrifying bacteria; whence it is deduced that these organisms are more resistant to higher osmotic pressure than ordinary plants. In the soil itself, the nitric nitrogen remained constant in the case of the saline soil and a sterile patch, but in washed saline soil the nitric nitrogen after 5 weeks was 6 mgrms. with 16 mgrms. of nitrous nitrogen, and in washed saline soil inoculated with normal soil the nitric nitrogen increased to 11 mgrms. with 9 mgrms. of nitrous nitrogen. (3) Fixation of nitrogen. A nutrient mannitol solution was prepared, to which calcium carbonate was added. This was sterilised and then inoculated with the soil emulsion, and incubated for 11 days. The total nitrogen was determined, a blank being done with sterile soil. It was found that the saline soil fixed 1.2 mgrms. of nitrogen, a sterile patch 7.8 mgrms., and normal soil 7 mgrms. This showed that *Azotobacter chroococcum* must have a higher osmotic pressure in its protoplasm than nitrifying and oxidising bacteria. As a result of these experiments, the barren land was washed with canal water and drained; on examining the reclaimed soil on the above lines, confirmatory results were obtained. Photographs of the land before treatment, and with the first and second year's crops after treatment, are inserted, and full details of the crop yields are given.—J. H. J.

Soils; Variation in the chemical composition of — W. O. Robinson, L. A. Steinkoenig, and W. H. Fry. Bull. No. 551. U.S. Dept. Agric., June 26, 1917. 16 pages.

THE main constituents in 45 typical American soils, ranging from fine sandy loams to heavy clay loams, were determined. The results confirmed previous observations that where there is a distinct sub-soil, differing in colour and texture from the surface soil, there may be a pronounced difference in the chemical composition of the two, especially in the respective amounts of silica, iron, and alumina. Thus, in the case of the samples taken from 34 places, the silica was higher in the surface soils in all but two instances, the iron in all but five, and the alumina in all but one. The extreme variations of the constituents were as follows:—Silica, 97.01 to 44.15; iron oxide, 16.23 to 0.23; alumina, 27.58 to 1.19; potash, 4.07 to 0.02; soda, 2.06 to 0.01; lime, 1.73 to 0.01; magnesia, 1.93 to 0.01; phosphoric acid (P_2O_5), 0.22 to 0.03; and sulphuric acid, (SO_3) 0.34 to 0.02%. Some soils of the same type may differ considerably in chemical composition, and, on the other hand, soils of different types may resemble each other as closely in chemical composition as different samples of the same type. Owing to unavoidable analytical errors differences of several hundred lb. are not significant when the amounts of the constituents are stated in lb. per acre. (C. A. M.)

Soils; Methods for determining the reaction of — H. R. Christensen. Soil Sci., 1917, 4, 115—178.

IT is necessary to distinguish sharply between the absolute acidity of the soil, and its ability to absorb bases (i.e., to liberate acids). The majority of methods for making a quantitative determination of the acidity of the soil give no information as to the content of truly acid-reacting substances in the soil, i.e., substances which in solution cause a hydrogen-ion concentration greater than corresponds to the value 10^{-7} ; but only of its ability to absorb bases. All mineral soils showing an acid reaction to litmus have a large lime-requirement. In such instances a quantitative deter-

mination of the acid content of the soil, which expresses the amount of lime necessary for neutralising the acid present, will also give reliable though insufficient information as to the degree of the lime requirement of the soil. Many soils which show a neutral reaction to litmus, however, have a decided lime-requirement, and in such cases it is impossible to use the acidity determination in determining the degree of the lime-requirement of the soil. It is probable that this question of the lime-requirement of the soil is predominantly a question of the presence or absence of certain easily decomposed acid-saturating calcium (or magnesium) compounds, and that the efforts to find a quantitative expression for the lime-requirement should be in the direction of methods which can express the amount of lime-fertiliser necessary for supplying the soil with a sufficient quantity of such compounds. J. B. C. K.

Soils; Adsorption by — J. E. Harris. J. Phys. Chem., 1917, 21, 151—473.

EXPERIMENTS are described which were undertaken to determine whether the acidity of those soils which reddened litmus paper, but which give a neutral solution, is due to colloidal adsorption. Soil was placed in contact with dilute solutions of barium chloride for 24 hrs., with occasional shaking, and the amount of barium in solution before and after the treatment determined. When the results were calculated according to the equation $x/m = a \cdot c^b$, representing the adsorption isotherm, the values obtained for $1/m$ were constant, showing that the action was one of adsorption and not of double decomposition. No chlorine was adsorbed from the barium chloride. Solutions containing other metallic ions were also used, and it was found that the number of equivalents adsorbed was the same for ions of the same valency and increased with the valency, except in the case of potassium, which was adsorbed in very high quantity. The potassium adsorbed by a soil could be recovered by treatment with salt solutions, again in the order of the valency of the metal. When a soil was treated with a solution of two salts, the number of equivalents of each metallic ion adsorbed was less than with each salt separately, but the total number was greater. J. H. J.

Cyanuric acid from soil; Isolation of — L. E. Wise and E. H. Walters. J. Agric. Res., 1917, 10, 85—91.

CYANURIC acid was separated from soils obtained from various parts of the United States (Maine, Texas, Florida, and Indiana), the largest amount found being 0.150 gm. from 23 kilos. of the Indiana soil. W. P. S.

Ammonia formation in soil; Effect of different salts on — G. P. Koch. J. Biol. Chem., 1917, 31, 111—113.

DRIED blood was added to soil together with varying combinations of the three salts, magnesium sulphate, potassium sulphate, and calcium dihydrogen phosphate, the soil solution being made up to an osmotic pressure of two atmospheres. The mixture was incubated for 8 days and the ammonia determined. When the calcium phosphate was present as $\frac{1}{10}$ of the molecular proportion of the total salts, there was a considerable increase in the ammonia formed over the same soil without the salts. When it formed $\frac{1}{10}$ of the combination or was used alone, there was an increase of 26% of ammonia over the normal; when it was absent, the magnesium and potassium sulphates caused the ammonia formation to fall below the normal.—J. H. J.

Calcium cyanamide: Addition of tar to — to facilitate spreading. Schmoeger and Lucks. Mitteil. deutschen Landwirts.-Ges., 1917, No. 10, 156—157. Bull. Agric. Intell., 1917, 8, 842—844.

EXPERIMENTS have been carried out in Germany with a mixture of calcium cyanamide with 15% coal tar, the cyanamide being first mixed with the tar, and then passed through a mincing-machine. The material obtained in this way is similar in appearance to superphosphate, and can be easily spread over the soil without powdering. Pot-manuring experiments were carried out with oats in 1915 and 1916, and proved that the tar had no deleterious effects upon the plants. Experiments carried out in the open with wheat in 1915—1916 confirmed the results of the pot-trials with oats, the relatively small increase of the manured plots in this case being ascribed to the bad conditions which prevailed when the wheat was sown.

—J. B. C. K.

Nitrogenous manures: Comparative action of ammonium sulphate, sodium nitrate, and some organic —. I. Jakouchkine. Annals Agric. Inst. Moscow (Russian), 1916, 22, 137—141. Bull. Agric. Intell., 1917, 8, 700—701.

OATS, flax, and potatoes were grown in soil to which the following manures were added: mono-potassium phosphate and potassium chloride, together with castor oil cake, horn-scrappings, fish, peat-litter, sodium nitrate, or ammonium sulphate. The proportions used were equivalent to 25 parts of N, 2 parts of P_2O_5 , and 4 parts of K_2O . It was found that in clay soil ammonium sulphate was preferable to sodium nitrate, because it dissolved the phosphate added as well as that in the soil. Horn scrappings and castor oil cake were about equal in value to sodium nitrate, the action of the horn being possibly partly due to its sulphur content. The assimilation of the nitrogen of fish manure was about half that of sodium nitrate. Peat litter gave up its nitrogen more readily than ordinary litter.—J. H. J.

Potash salts: Substitution of finely crushed Austrian phonolites for Stassfurt —. J. Stoklasa. Oester.-ung. Zeits. Zuckerind. u. Landwirtsch., 1916, 45, 121—156. Bull. Agric. Intell., 1917, 8, 698—700.

IN Austria, phonolite powder has been used as a substitute for Stassfurt salts, chiefly as a fertiliser for beet. The phonolite is found in central Bohemia, and in most cases the nepheline usually present is replaced by sodalite. A table of the different varieties is given, showing the respective amounts of total potash which vary from 5.74 to 8.54%. The percentage of this potash which is soluble in concentrated hydrochloric acid is very variable, the extremes being 21.44% and 54.7%. Only a small amount of the potash is soluble in a saturated solution of carbon dioxide. Experiments were made upon the influence of phonolite upon the growth of soil bacteria; the increases in growth and activity were found to be small compared with those effected by kainit.—J. H. J.

Plants: Action of bacteria and fungi in the tissues of —. E. Berthold. Jahrb. wissensch. Botanik, 1917, 57, 387—458. Bull. Agric. Intell., 1917, 8, 704—705.

EXPERIMENTS were made on the depth to which bacteria and fungi could penetrate the tissues and their longevity in them. It was found that the tissues of herbaceous plants and the sap and heart-wood of woody plants are normally free from bacteria. Where wood is attacked by fungi, their presence can be demonstrated in the wood, but bacteria are never present at the same time.

The vessels of a section of a woody plant placed in water become infected with bacteria and the spores of fungi from the water are absorbed, the penetration depending upon the length of the vessel. Bacteria injected into the tissues of living herbaceous plants and into living wood, remain alive for as long as ten months, but no sign of any development can be observed. Dead tissue only can be utilised for bacterial growth.—J. H. J.

XVII.—SUGARS ; STARCHES ; GUMS.

[American] invert sugar syrups: Sources and composition of some commercial —, with notes on sorghum syrup. S. Jordan and A. L. Chesley. J. Ind. Eng. Chem., 1917, 9, 750—758.

IT is estimated that in 1916 more than two million gallons of invert sugar syrups was used in the United States. American "light syrup," made from refined sugar, usually consists of a large proportion of invert sugar (70 to 78%) with a small proportion of unchanged sucrose (0.5 to 4.0%) and from 0.05 to 0.2% of acidity calculated as tartaric acid. In some samples hydrochloric acid (up to 0.15%), partly free and partly combined, has been found. The mineral matter present is small, varying from traces to about 0.5%. Some brands of light syrup contain, however, much more sucrose (up to 33.0%). "Dark syrup" is invert made from raw sugars or mixtures of (i.), invert from raw sugar and molasses; (ii.), "light syrup and molasses; or (iii.), invert with soured honeys, along with wastes from sugar houses. It rarely contains more than 72.5% of total sugars, a varying amount of which is invert sugar, viz., 18.0—73.0%. The ash varies from 0.5 to 3.5%.

Glycerin (95%) will take up about 15% of moisture, whilst invert syrups will retain about 14%, but the latter require the application of a high temperature to obviate their stickiness and cause them to penetrate in the same way as glycerin. They may replace glycerin, however, in cases where the latter has been used to counteract the effects of crystallisable sugar. For these purposes the authors suggest the following standards:—(1) *Light syrup special* to contain at least 75% of total sugars (invert and sucrose), the proportion of the sucrose not to exceed about 2.5%. The ash should not exceed 0.02% and the acidity, which should be entirely due to organic acids, not to exceed 0.1%, calculated as tartaric acid. (2) *Light syrup* should be similar to (1), except that the sucrose should not exceed 20%. The syrup should be bought on its total sugar units. (3) *Dark syrup special* should be made from raw sugar and a suitable organic acid which should not exceed 0.3% by weight of the

syrup. It should contain at least 75% of total sugars (sucrose and invert sugar only) and the sucrose should not exceed 5%. The ash should not exceed 0.5%. (4) *Dark syrup* should be made from any suitable blend of invert syrups and molasses. It should not contain less than 72.5% of total sugars, of which at least two-thirds should consist of invert sugar. The ash should not exceed 2.5% and the acidity should not exceed 0.3%.

Sorghum syrup.—It is estimated that about 17 million gallons of sorghum syrup was produced in 1900 in the United States, and since that time the industry has developed in certain districts. The average cost of production is estimated at about 19 cents (9.5 pence) per gall. The syrup is capable of being used as the source of all the "dark invert syrups," and by passing the dark syrup through animal charcoal it could also be used to produce the light syrups, at a probable cost of about 75% of that of the invert syrups made from cane sugar. A representative sample had the following composition:—Total solids, 74.6; ash, 2.4; sucrose, 1.0; reducing sugars, 28.4; "gums" and extractives, 4.0; and acidity (as tartaric acid), 0.8%. The "gums" consisted largely of starch and dextrin. A sample was exposed for six weeks without crystallising, and then contained about 15% of water. The finished syrup should contain at least 70% of total sugars, not more than 5% of starch and gums, and not more than 3% of mineral matter; whilst the acidity should not be more than about 0.8%.

Decolorising-carbon. See IIb.

PATENT.

[*Sugar*] *liquors*: *Treatment of certain*—. F. A. Monroe, jun., Assignor to The Dyer Company, Cleveland, Ohio. U.S. Pat. 1,236,997, Aug. 7, 1917. Date of appl., Mar. 8, 1916.

COLD saccharate waste water is heated by mixing with steam from the evaporation of sugar solutions to cause precipitation of saccharate, which is then separated from the liquid. The heating may be effected in stages: e.g., apparatus is claimed in which the cold waste water is first warmed by injection into a heater receiving steam from the last unit of a multiple-effect evaporator and then further heated by injection into a second heater receiving steam from an earlier unit.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Beer: *Distribution of nitrogen in*—. J. S. Sharpe. Biochem. J., 1917, 11, 101-111. (See also H. T. Brown, this J., 1907, 881).

A QUANTITATIVE investigation was made of typical British beers, to ascertain the amounts of the different classes of nitrogenous substances present. The total nitrogen-content of the samples ranged from 0.039 to 0.112%. Of this, 13-37% was present as protein, which was determined by precipitation with tannic acid in presence of a little phosphoric acid, 25-46% was present as amino-compounds, determined by Van Slyke's method, and 25-52% was purine nitrogen present as uric acid and xanthine compounds, leaving a balance of 2-6% of the total nitrogen undetermined. Of the purine nitrogen, uric acid accounted for proportions ranging from 15-90% in the different samples. Tests for hypoxanthine, adenine, guanine, and methylpurine gave negative results. From beers rendered alkaline with sodium hydroxide, chloroform extracted small quantities (0.007-0.012%) of an oil of

alkaloidal character, which darkened in the air, was fairly volatile at 190°C., had an odour like that of juice from a tobacco pipe, and gave many of the reactions of cocaine, which Chapman found in hops (see this J., 1911, 879). This substance, together with a small quantity of a base, probably betaine, almost completely accounted for the 2-6% of the total nitrogen referred to above as undetermined.—J. H. L.

Micro-organisms and heat production in silage fermentation. Hunter. See XIXa.

PATENTS.

Beer: *Process of treating*—. C. S. Ash, Assignor to Gould and Ash, San Francisco, Cal. U.S. Pat. 1,234,255, July 21, 1917. Date of appl., Feb. 4, 1916.

BEER is stabilised by treating the wort or the fermented beer with a mixture of tannin or a tannate and sulphurous acid or a sulphite, and removing the precipitate formed; e.g., krausened beer may be treated with 35-60 mgrms. of tannin and 25-50 mgrms. of sulphurous acid per litre to prevent it acquiring a "cooked" flavour and becoming discoloured after pasteurisation.

—J. H. L.

Beer wort: *Apparatus for cooling and rousing*— and for precipitating sludge from the same. L. Nathan, Zürich, Switzerland. U.S. Pat. 1,235,231, July 31, 1917. Date of appl., July 7, 1911.

A CLOSED receptacle for the hot wort has within it a number of cooling plates over some of which the wort flows in a thin layer. Means are provided for cooling the plates and passing air over the surface of the wort. The plates are connected with one another, and are removable together to enable the sludge to be washed from them.

—J. H. L.

[*Alcoholic*] *beverages*: *Process of preparing*—. *Product for brewers' use*. G. Deffen, Newton, Mass. U.S. Pats. (A) 1,235,881 and (B) 1,235,882, Aug. 7, 1917. Date of appl., Mar. 27, 1917.

(A) Two modifications of the process described in U.S. Pat. 1,214,518 (this J., 1917, 399) are claimed, viz., carrying out the heating of the material containing starch and protein with acidulated water in presence of hops, and treating the products of the heating with a proteolytic enzyme. (B) Claim is made for unfermented liquid products, or concentrated residues obtained therefrom by evaporation, containing fermentable sugars and protein, and prepared from amylaceous and nitrogenous matters as described in U.S. Pats. 1,214,518 and 1,235,881 (see above). The products may contain active proteolytic enzymes.—J. H. L.

Method of deliming wool, hair, or like substances contaminated with lime. U.S. Pat. 1,235,214 See V.

XIXa.—FOODS.

Milk fat of the cow and sheep: *Distribution of the fatty acids in the*—. C. Crowther and A. Hynd. Biochem. J., 1917, 11, 139-163.

THE method employed for separating the fatty acids consisted in heating an ethereal solution of the fat with an excess of methyl alcohol containing a small quantity of hydrogen chloride, separating the mixed methyl esters thus formed, and subjecting them to repeated fractional distill

ation, the first fractions being distilled under ordinary pressure and the later ones under 15 mm. pressure. The weight of each ester in the various fractions was calculated from the iodine and saponification values. The following average percentages of fatty acids were found in fat from cow's milk: butyric acid, 4.27; caproic acid, 1.61; caprylic acid, 1.16; capric acid, 1.19; lauric acid, 5.01; myristic acid, 16.13; palmitic acid, 11.83; stearic acid, 3.10; dihydroxystearic acid 0.38; oleic acid, 11.12. In fat from sheep's milk: butyric acid, 6.51; caproic acid, 1.18; caprylic acid, 1.23; capric acid, 1.79; lauric acid, 4.70; myristic acid, 13.71; palmitic acid, 13.31; stearic acid, 4.39; dihydroxystearic acid, 0.27; oleic acid, 40.67. In the case of fat from cow's milk there was 9% less myristic acid, 6% more palmitic acid, and 3% more stearic acid in the fat from the "first runnings" than in that from the "last runnings."—W. P. S.

War bread: Improvement of—by neutralising the bran. Lapicque and Legendre. *Comptes rend.*, 1917, 165, 316–319.

BREAD made from flour containing a considerable quantity of bran is greatly improved in appearance and taste if lime-water is used in place of water in preparing the dough.—W. P. S.

Alfalfa (lucerne) silage: Chemical studies in making— C. O. Swanson and E. L. Tague. *J. Agric. Res.*, 1917, 10, 275–292.

EXPERIMENTS were made on a laboratory scale in bottles and also on a larger scale using a 10-ton silo. It was found that silage can be made from alfalfa alone if the containers insure absolute exclusion of air and retention of carbon dioxide, but such conditions cannot be obtained on a practical scale. The addition of supplementary substances (e.g., molasses, rye, maize, etc.), increases and accelerates the production of acids, and the presence of these is unfavourable for the development of putrefactive organisms. Wilted alfalfa is more suitable for making silage than is unwilted; the addition of water to wilted alfalfa has no effect, but is injurious to unwilted alfalfa. Molasses is the most effective supplementary substance to use; germinated maize is very similar to molasses in its action and is more effective than sound maize. Rye has a strong odour when made into silage. Alfalfa itself contains only a small quantity of amino-nitrogen; in good alfalfa silage the amino-nitrogen is about one-third of the total nitrogen (6.6%) whilst in bad silage it is about one-half of the total nitrogen. The acidity of silage varies from 2 to 3% (as lactic acid) and the greater part of the acidity is produced during the first 10 days. Sugar, when added to silage, disappears very quickly, and is never present in completely matured silage.—W. P. S.

Silage fermentation: Micro-organisms and heat production in— O. W. Hunter. *J. Agric. Res.*, 1917, 10, 75–83.

SINCE heat production in fermenting forage (silage) is prevented when the material has been heated previously or treated with chloroform, it is concluded that the heat production is due to bacterial activity and not to intramolecular respiration of the tissue cells.—W. P. S.

Feeding-stuffs: New—used in Germany during the war. M. Kling. *Landwirtsch. Jahrb. f. Bayern*, 1916, 6, 183–513. *Bull. Agric. Intell.*, 1917, 8, 892–899.

(1) *Rhubarb leaves.* The green leaves contain 90% of moisture, 2.78% of protein, and 0.1% of fat.

The dried leaves are said to be better than hay of the first quality. (2) *Seaweed.* As a rule seaweed contains little protein and fat, but a large quantity of nitrogen-free extract and crude fibre. When used as a feeding stuff, no trace of its smell could be found in the meat or in the eggs. It is advisable to give the seaweed in the ground, dry state, as a supplementary food. (3) *Straw meal.* The ground straw of cereals is unsatisfactory for pigs, cattle, and horses. (4) *Spelt chaff meal* is not superior to whole chaff. (5) *Concentrated straw fodder.* By boiling straw in an alkaline solution under pressure, a concentrated, easily digested food is obtained. It is mixed with about 30% of molasses and the whole dried. The product contains 3.55% of protein (amides), 29% of nitrogen-free extract, and 53% of fibre. To supply the deficiency in albumin, the fodder was enriched by the addition of dried yeast, now replaced by ground lupin seeds freed from their bitter elements. Thus enriched, it contains 6–10% of protein, 14–15% of nitrogen-free extract, and 28–34% of fibre. Feeding experiments showed this product to be suitable for all animals, and capable of replacing oats for horses. (6) *Crushed and ground maize ears.* The feeding value does not exceed that of wheat chaff, and it is not recommended. (7) *Heather stalks.* An excellent food may be prepared from the leaves, flowers, seeds, and fine stalks of heather. It contains about 4% of protein, 3% of fat, 45% of nitrogen-free extract, and 35% of fibre. (8) *Kohl-rabi by-products.* The decomposing roots, made into slices and then dried, gave a fairly good food. Another food prepared from the peelings contained so much sand that it could not be used with safety. (9) *Ground sugar-beet seeds.* Seeds which have lost their germinating power are ground. They contain about 11% of protein, 1% of fat, and 9% of mineral matter. Their nutritive value is two-thirds that of wheat bran. (10) *Parsley seed.* Seed which had remained unsold was crushed. It contains about 23% of crude fat, and can be given in moderate amount to animals receiving rations poor in stimulants. (11) *Wild radish husks.* Nutritive value 40% that of good barley. Not suitable for pigs. (12) *Mixture of brewers' grains and yeast.* By a special process the dry grains are mixed with the moist yeast, and the whole dried. The mixture contains about 75% of grain and 25% of yeast, and is most suited for horses and cattle. (13) *Wine yeast.* The fresh yeast is washed to free it from tartar and made into a cake. (14) *Ground grape pips.* The pips are obtained from grape residues after distillation to remove alcohol. They are ground, and form a food very rich in crude fibre, with a nutritive value corresponding to that of medium quality meadow hay. (15) *Beechnut cake.* The ground nuts contain about 18% of protein, 4% of fat, 28% of nitrogen-free extract, 19% of fibre, and 11% of mineral matter including 6.5% of sodium chloride. The last was added to disguise the taste of tannin, in which the nuts are very rich. (16) *Walnut cake.* The nuts are pressed with the shells and give a cake very similar to beechnut cake. The cake is also prepared from nuts pressed without their shells, and then forms a food readily eaten by cattle. (17) *Food for fattening pigs.* Six varieties are described, only two of which are considered satisfactory: one, made from crushed maize, ground maize ears, and acorn meal, contained about 9% of protein and 3% of fat; the other was composed of corn bran, crushed corn, barley, oats, acorn meal, ground seeds of weeds, seaweed meal, and fish meal, and contained 15% of protein. (18) *Poultry food.* Many by-products of little value are being sold. (19) *Horse food.* One is made from corn chaff, dried beetroot, and pea meal. (20) *Feeding meal.* One contained ground spelt chaff, ground grape residue, straw meal, and 2.5% of sodium chloride.—J. H. J.

Cottonseed meal; Nutrition investigations upon —. III. Cottonseed flour. The nature of its growth-promoting substances, and a study in protein minimum. A. E. Richardson and H. S. Green. *J. Biol. Chem.*, 1917, **31**, 379—388. (See this J., 1916, 860; 1917, 937.)

SUFFICIENT of an ether extract of cottonseed flour was added to a balanced diet to represent 50% of flour in the diet, which was then fed to white rats, with the result that the growth of the animals was retarded, showing a deficiency of the fat-soluble food accessory in the flour. When the extract was increased to represent 138% of flour, growth became normal again. When an aqueous extract of the flour corresponding to 50% of flour was added to the diet, growth was normal, showing the flour to contain sufficient water-soluble accessory. To determine the minimum of protein as cottonseed flour which could be used in a diet, varying amounts of the flour were added to balanced diets to give a content of 4—18% of protein. The 18% diet gave practically normal growth in the rats, although the second generation were slightly undersized. With a 12% diet the growth was slightly below normal, with a 6% diet there was very little growth, and with a 4% diet the rats lost weight rapidly at first, but continued alive and active.—J. H. J.

Perraporation, perdistillation, and percrystallisation. Koher. See I.

PATENTS.

Food substances; Preserving —. L. Fulda, Bow. Middlesex. Eng. Pat. 108,616, Nov. 25, 1916. (Appl. No. 16,937 of 1916.)

AN intimate mixture of about 92% of sodium bisulphite and 8% of sodium bisulphate, both powdered finely to pass through a sieve with 60 meshes to the inch, is stored in air-tight vessels for use as a food-preserving material. In use, a very small proportion of the mixture is incorporated with the food, solid or liquid, to be preserved, the substance being heated if necessary to 150° F. (65.5° C.); the contained moisture in the food is sufficient to render the composition active.—J. H. J.

Preserving vegetables, fruits, and the like; Process for —. J. von Epler, New York. U.S. Pat. 1,236,382, Aug. 7, 1917. Date of appl., Jan. 3, 1917.

THE substance to be treated is pulped and the juice separated from the fibrous material by pressure. The juice is concentrated below 212° F. (100° C.) to the consistency of a syrup, the fibrous material is impregnated with fat above 212° F., and the two are recombined, with the addition of 5% of salt if required.—J. H. J.

Milk; Process of drying —. J. Roch, Assignor to Crystallized Milk Co., Spokane, Wash. U.S. Pat. 1,235,161, July 31, 1917. Date of appl., Mar. 14, 1910.

A SMALL quantity of milk is instantaneously warmed under pressure, then heated at about 140° F. (60° C.) until dry, when the temperature is raised to 170° F. (about 77° C.).—J. H. J.

Maize; Manufacture of — into fine flour. J. and F. W. Parker, Limerick, Ireland. Eng. Pat. 108,803, Jan. 8, 1917. (Appl. No. 342 of 1917.)

Method and apparatus for indicating the volumetric flow of gases [for flour bleaching]. Eng. Pat. 108,711. See XXIII.

XIXB.—WATER PURIFICATION; SANITATION.

Iodide of starch; Use of — in treatment of infected wounds. A. Lamière. *Comptes rend.*, 1917, **165**, 376—377.

IN the disinfection of wounds it is desirable to use a reagent which is not destroyed quickly by the tissues, and which will continue active for several days. Experiments proved that 10 grms. of muscle tissue, showing incipient decomposition, decolorised 100 c.c. of iodine solution, containing 25 mgrms. of iodine, in half-an-hour, and putrefaction proceeded in the ordinary course; whereas under the same conditions iodide of starch containing the same weight of iodine retained its blue colour for a month. It was found that iodide of starch, containing one part of iodine in 50,000 parts, was effective in killing *Streptococci*, *B. coli*, and *B. pyocyaneus* in 24 hrs. at 37° C.; and a much weaker solution was effective against *Staphylococci*. Iodide of starch containing 1% of iodine was found a convenient strength in practice to use in dressing battle wounds, and caused them to remain sterile for three dressings. A solution of iodide of starch containing 0.5 gm. of iodine per litre can be used in the irrigation method of treating wounds, and is as effective as Dakin's solution (this J., 1915, 919) and not irritant to the tissues.—J. H. J.

Arsenates; Toxic values of —. A. L. Lovett and R. H. Robinson. *J. Agric. Res.*, 1917, **10**, 199—207.

COMPARATIVE tests of the toxic action of solutions of different arsenates upon the common tent caterpillar (*Malacosoma phucialis*), have shown that lead hydrogen arsenate (Robinson and Tartar, this J., 1914, 1008) is more effective than solutions of calcium or basic lead arsenates of the same strength. The amount of arsenic retained by insects feeding upon foliage sprayed with arsenates varies with the arsenate used. Thus, in the case of lead hydrogen arsenate most of the arsenate is retained in the tissue, whilst a large proportion of basic lead acetate is rapidly eliminated. It requires about 0.1595 mgm. of arsenic pentoxide to kill 1000 small tent caterpillars, and about 1.84 mgrms. to kill 1000 nearly mature caterpillars, irrespective of the particular arsenate used for the spray. Preliminary field tests with sprays of calcium arsenate and calcium ammonium arsenate showed that they cause too severe injury to the foliage of trees to be safe spraying materials.—C. A. M.

Determination of ozone and oxides of nitrogen in the atmosphere. Usher and Rao. See VII.

PATENTS.

Filtration; Art of —. Filtering apparatus. W. M. Jewell, Assignor to Jewell Engineering Co., Chicago, Ill. U.S. Pats. (A) 1,232,805 and (B) 1,233,061, July 10, 1917. Dates of appl., Oct. 23 and Nov. 16, 1915.

(A) IN washing a filter acting under gravity, use can be made of the filtered water for this purpose, by shutting off the inflow of water to the filter, applying suction above the level of the filter material and drawing the filtered water in a reverse direction through the material. (B) The apparatus consists of a chamber containing one or more filter beds, separately enclosed above and connected together at the bottom. Each bed has a separate water inlet situated above the level of the filter material, and a common outlet pipe at the bottom, emptying into a receiver. For washing the beds, suction means are provided

connected with the inlets, whereby water is drawn from the receiver upwards through the material.

—J. H. J.

Boiler-water; Process of treating —. H. Kriegsbom. Assignor to The Permutit Co., U.S.A., New York. U.S. Pat. 1,235,815, Aug. 7, 1917. Date of appl., Apr. 22, 1915.

A HIGH concentration of a corrosion-preventing dissolved salt is established in the water in the boiler, and some of the boiler water is run back into the heated feed-water before the latter is run into the boiler.—J. H. J.

Sterilising apparatus [using ultra-violet radiations]. F. G. Keyes, Boston, Mass., Assignor to Cooper Hewitt Electric Co., Holoken, N.J. U.S. Pat. 1,235,698, Aug. 7, 1917. Date of appl., July 1, 1915.

A GAUZE screen of fibrous material is supported so as to hang in a vertical plane, and the liquid to be sterilised is distributed along the top of the gauze. A source of ultra-violet radiations is provided in proximity to the gauze, and the sterilised liquid is cooled by passing it into a trough at the bottom.

—B. N.

Insecticide or fungicide [Paris green] and method of making the same. R. V. Brown, Chicago. Assignor to The Sherwin-Williams Co., Cleveland, Ohio. U.S. Pat. 1,235,285, July 31, 1917. Date of appl., July 13, 1914.

IN the manufacture of Paris green the solution containing sodium arsenite or sodium and copper arsenites is precipitated by the addition of lime, the precipitate treated with lead arsenate, and copper sulphate and lime added to the mixture. By this method loss of arsenic and copper is prevented, and an insecticide may be obtained containing approximately 58% of calcium and copper arsenites, 8% of lead arsenate, 14% of copper hydroxide, and not more than 20% of inert substances.—B. V. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Tropinone; Synthesis of —. R. Robinson. Chem. Soc. Trans., 1917, 111, 762–768. (Compare Willstätter, this J., 1903, 227.)

SUCCINDIALDEHYDE, acetone, and methylamine in aqueous solution at the ordinary temperature react with formation of a poor yield of tropinone. A better result is obtained by using a mixture of succindialdehyde, ethyl acetonedicarboxylate, and methylamine in alcoholic solution at the ordinary temperature, the primary reaction product, viz., ethyl tropinonedicarboxylate, being subsequently converted into tropinone by boiling with dilute sulphuric acid; a modification of this method applying succindialdehyde, methylamine, and calcium acetonedicarboxylate in aqueous solution at the ordinary temperature, likewise gives rise to

tropinone. The course of the synthesis may be represented thus—

For the identification of the tropinone obtained it was found convenient to convert this into its dipiperonylidene derivative, $\text{C}_{24}\text{H}_{21}\text{O}_5\text{N}$, bright yellow needles, m. pt. 214°C ., which forms a yellow hydrochloride crystallising in microscopic needles.

—D. F. T.

Ginger; Pungent principles of —. A new ketone, zingerone (4-hydroxy-3-methoxyphenylethyl methyl ketone) occurring in ginger. H. Nomura. Chem. Soc. Trans., 1917, 111, 769–776.

ON extracting powdered ginger with ether, a crude solution of a ketonic-phenolic substance is obtained; this can be isolated by removal with dilute sodium hydroxide solution, liberation by carbon dioxide, separation of the accompanying acidic impurities by treatment with sodium carbonate solution, and subsequent distillation under reduced pressure. The resulting zingerone, $\text{C}_{11}\text{H}_{14}\text{O}_3$, forms colourless crystals, m. pt. $40^\circ\text{--}41^\circ\text{C}$., and gives a sodium bisulphite compound, a benzoyl derivative, colourless crystals, m. pt. $126^\circ\text{--}127^\circ\text{C}$., an acetyl derivative, m. pt. $40^\circ\text{--}42^\circ\text{C}$., b. pt. $204^\circ\text{--}205^\circ\text{C}$. at 14 mm., a methyl ether, $\text{C}_{12}\text{H}_{16}\text{O}_3$, m. pt. $55^\circ\text{--}56^\circ\text{C}$.; b. pt. $186^\circ/16\text{ mm}$. (compare Kaufmann and Radosevic, Ber., 1916, 49, 675), and an ethyl ether, $\text{C}_{13}\text{H}_{18}\text{O}_3$, m. pt. 66°C .; the methylzingerone forms an oxime crystallising in colourless needles, m. pt. $93^\circ\text{--}93.5^\circ\text{C}$. From the behaviour of the zingerone in producing these derivatives the presence of one hydroxyl group must be assumed, whilst its reaction with bisulphite and its relative resistance to oxidation by ammoniacal silver nitrate indicate the presence of a ketonic group. On oxidation with sodium hypochlorite, ethylzingerone yields ethylvanillic acid, whilst methylzingerone with potassium permanganate gives veratric acid; with sodium hypobromite the methyl-compound produces bromoform and β -3,4-dimethoxyphenylpropionic acid. These results are in good accordance with the identity of zingerone as 4-hydroxy-3-methoxyphenylethyl methyl ketone, $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_3(\text{OCH}_3)_2\text{OH}$, this structure being demonstrated also by a synthesis based on the reduction of 4-hydroxy-3-methoxystyryl methyl ketone, which is obtainable by the condensation of vanillin with acetone.—D. F. T.

Ginger; Pungent principles of —. I. Chemical characters and decomposition products of Thresh's "gingerol." A. Lapworth, L. K. Pearson, and F. A. Royle. Chem. Soc. Trans., 1917, 111, 777–790.

FROM the alcoholic extract of African ginger there was separated a refined "gingerol," constituting a viscous faintly yellow phenolic oil (compare Garnett and Grier, Pharm. J., 1907 [iv.], 25, 118), the further purification of which proved difficult. It was therefore converted by methyl sulphate and alkali into crystalline "methylgingerol," $\text{C}_{11}\text{H}_{14}\text{O}_4$ or $\text{C}_{11}\text{H}_{16}\text{O}_4$, needles, m. pt. 61°C .; $[\alpha]_D^{20} = +27.3$, in chloroform. This substance on treatment with hydroxylamine gave a hydrated oxime, and also appeared to contain a hydroxyl group. Gingerol, when oxidised with chromic acid, formed *n*-heptic acid and probably *n*-hexoic acid, whilst on treatment with baryta water it yielded *n*-heptaldehyde and zingerone, $\text{C}_{11}\text{H}_{14}\text{O}_3$, a ketonic phenolic substance crystallising in needles, plates, or rhombohedra, m. pt. $31^\circ\text{--}34^\circ\text{C}$., which was further converted into its phenyl-

hydrazone, m. pt. 143° C.; semicarbazone, m. pt. near 133° C.; ethylcarbonato derivative, $C_{11}H_{13}O_5 \cdot O \cdot CO_2C_2H_5$, prisms, m. pt. 45°—47° C., and methyl derivative, colourless needles, m. pt. 55.5°—56.2° C.; the last possessed no phenolic properties but yielded an oxime, $C_{12}H_{17}O_3N$, needles, m. pt. 91°—92° C., and reacted with sodium hypobromite giving bromoform and 3-3-4-dimethoxyphenylpropionic acid, whence it is probable that methylzingerone is to be represented as CH_3O

$CH_3O \text{---} \text{C}_6\text{H}_3 \text{---} CH_2 \cdot CH_2 \cdot CO \cdot CH_3$ (see preceding abstract). Gingerol itself must be essentially a mixture of optically active saturated phenolic compounds derived from zingerone in association with a molecular proportion of the residue of an aliphatic aldehyde, the chief being *n*-heptaldehyde: the constituents of the mixture are probably aldols of the general type—

—D. F. T.

Ginger; Pungent principles of—. *II. Synthetic preparation of zingerone, methylzingerone, and some related acids.* A. Lapworth and F. H. Wykes. Chem. Soc. Trans., 1917, 111, 790—798.

METHYLZINGERONE, needles, m. pt. 55°—56° C., was synthesised by the condensation of veratraldehyde and acetone to 3,4-dimethoxystyryl methyl ketone, $HO \cdot C_6H_3(OCH_3)_2 \cdot CH : CH \cdot CO \cdot CH_3$, with subsequent reduction of this product in alcoholic solution by means of sodium amalgam. Zingerone (4-hydroxy-3-methoxyphenylethyl methyl ketone), was obtained in poor yield by the condensation of vanillin with acetone, and reducing the resulting 4-hydroxy-3-methoxystyryl methyl ketone; much better results were obtained by reducing ethyl vanillylideneacetoacetate, and after hydrolysis of the product, causing the elimination of carbon dioxide by heating, the stages being—

3,4-Dimethoxystyryl methyl ketone on oxidation with aqueous sodium hypobromite gave rise to dimethylcaffeic acid, $C_6H_3(OCH_3)_2 \cdot CH : CH \cdot CO_2H$; ethyl vanillylideneacyanoacetate— $HO \cdot C_6H_3(OCH_3)_2 \cdot CH : C(CN) \cdot CO_2 \cdot C_2H_5$, yellow needles, m. pt. 107° C., prepared by the interaction of vanillin and ethyl cyanoacetate, on successive reduction, hydrolysis, and elimination of carbon dioxide was converted into hydroferulic acid, $C_{10}H_{12}O_4$, needles, m. pt. 89°—90° C. In a similar manner ethyl α -cyanoacrylate, $C_6H_3(OH)_2 \cdot CH : C(CN) \cdot CO_2 \cdot C_2H_5$, a yellow microcrystalline solid, m. pt. 162°—166° C., was obtained by the condensation of protocatechuic aldehyde with ethyl cyanoacetate, and by successive reduction, hydrolysis, and elimination of carbon dioxide, was made to yield hydrocaffeic acid.

—D. F. T.

Gingerol and paradol. E. K. Nelson. J. Amer. Chem. Soc., 1917, 39, 1466—1469.

THE main constituents of gingerol and paradol, the pungent essences of ginger and grains of paradise (*Amomum melegueta*) are monomethyl ethers of a dihydric phenol, the difference between them probably being due to the position of the methyl group. Gingerol is a pungent, yellow oil of which the sp. gr. at 20°/20° C. is 1.0713, $[a]_D = +12.9^\circ$, and $n_D^{20} = 1.5212$. It contains 9.26% of methoxyl. Methylation with dimethyl sulphate gives 43% of a non-pungent methyl ether, m. pt. 65°—65.5° C., $[a]_D = +9.3^\circ$, and 50% of a liquid product. On distillation, gingerol gives a main

reaction boiling at 227°—229° C. at 6 mm. pressure. This fraction is optically inactive, gives a green colour with ferric chloride, and does not give a crystalline ether on methylation. Its sp. gr. at 20°/20° C. is 1.0503, and $n_D^{20} = 1.5212$. Paradol is a pungent yellow oil of which the sp. gr. at 20°/20° C. is 1.0690, $[a]_D = +9.2^\circ$, and $n_D^{20} = 1.5232$. It contains 10.95% of methoxyl. On methylation it gives a crystalline product, identical with the methyl ether of gingerol, and an oil. The main fraction obtained by distilling paradol boils at 230°—234° C. at 8 mm. pressure, its sp. gr. at 20° C. being 1.0415 and $n_D^{20} = 1.5198$. It is optically inactive, and does not give a crystalline methyl ether. Gingerol and paradol differ in their stability on boiling with alcoholic caustic potash, the pungency of gingerol being practically destroyed, while that of paradol is only slightly affected. The work was discontinued when Lapworth's study of gingerol (see preceding abstracts) came to the notice of the author.—F. SP.

α -Hydroxypyridine and adenine; Alleged anti-neuritic properties of—. A. Harden and S. S. Zilva. Biochem. J., 1917, 11, 172—179. (See this J., 1916, 942, 1130.)

BOTH varieties (needles and granules) of crystallised α -hydroxypyridine were injected into polyneuritic pigeons, but no cure or amelioration in the condition of the birds was observed; re-crystallised α -hydroxypyridine also proved to be ineffective. Pure adenine, as well as adenine which had been treated with sodium ethoxide in a sealed tube for 5 hours at 100° C., had no curative action.—W. P. S.

Alkali butyrates; Oxidation of—by hydrogen peroxide with the production of succinic acid. E. Cahen and W. H. Hurteley. Biochem. J., 1917, 11, 164—171.

EXPERIMENTS were made on the oxidation of sodium butyrate (1 grm.-mol.) in aqueous solution by hydrogen peroxide (3, 6, or 12 grm.-mols.) at 37° and 65° C.; the total volume was in most cases 190 c.c. Besides aldehydes, acetone, and carbon dioxide, and small quantities of volatile acids, succinic acid was formed in quantity corresponding under the most favourable conditions to a yield of over 50% of the theoretical amount, referred to the weight of butyric acid oxidised. The results indicate that when oxidised by hydrogen peroxide, the butyric acid molecule may be broken down by attack at the α -carbon atom, with formation of propionic aldehyde and acid, etc.; at the β -carbon atom, with formation primarily of acetoacetic acid and then of acetone and carbon dioxide; and at the terminal carbon atom of the methyl group, with formation of succinic acid. It is considered that the last-mentioned mode of attack is by far the most important.

Gaseous hydrocarbon and chlorine or other gaseous halogen; Manufacture of products from reaction between—, and apparatus for use in such manufacture. B. S. Lacy, Sewaren, N.J., U.S.A. Eng. Pat. 101,708, Sept. 27, 1916. (Appl. No. 13,755 of 1916.) Under Int. Conv., Oct. 6, 1915.

In the chlorination of methane, the chlorine is diluted with a part of the methane and this mixture

then treated with the rest of the methane heated to a suitable temperature. In the apparatus described, the stream of methane is divided into two parts in any desired proportion, one part passing into the chlorine supply tube and the other part passing through a heating chamber and then joining the chlorine-methane stream just before its entry into the reaction chamber. The leading-in pipes for the chlorine and the heated mixed gases are made of silica, or similar substance unaffected by chlorine, and the reaction chamber, made of metal, is lined with similar resisting material, assisted by packing such as ground flint between the lining and the metal outer case and on the floor of the chamber. The heat supplied to the one portion of methane is arranged to supplement the heat of reaction so as to give a temperature of 300° — 500° C. and the reaction chamber is supplied with external heating appliances sufficient to keep the outer shell at the temperature of the interior. For instance, in the manufacture of monochloromethane, about 5 parts of methane is mixed with the chlorine and a further 10 parts heated to about 300° — 500° C. and then mixed with the first mixture. The method is applicable to other hydrocarbons and to other halogens.—B. V. S.

Oil gas; Chlorination of — B. T. Brooks and D. F. Smith, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,235,283, July 31, 1917. Date of appl., Mar. 16, 1916.

OIL-GAS is chlorinated by the progressive action of sulphuryl chloride at a temperature of 10° — 40° C.—B. V. S.

Ether; Apparatus for the continuous manufacture of — E. Barbet et Fils et Cie., Paris. Eng. Pat. 101,721, Oct. 6, 1916. (Appl. No. 14,236 of 1916.) Under Int. Conv., Oct. 7, 1915. Addition to Eng. Pat. 100,406, May 5, 1915 (this J., 1917, 569).

ALCOHOL passes through the valve, R, into the heater, D'. D' is heated by the condensed

water from the steam-heated vessel, C, and D' may be heated by steam, the supply of which is controlled by the float, H, and the valve, S. From D' the alcohol passes, either as vapour by d, d, or as hot liquid by d', d, according as D' is heated or not, to the mixing chamber, D, containing regenerated sulphuric acid from a previous operation. The ethylsulphuric acid then passes into a lead coil in the heated vessel, C, where it is decomposed and the mixture forced upwards by its own vapour pressure into the separator, F. The acid separated in F passes back by the pipe, c, into the pipe, d. Greater strength and durability of the coil and chamber, C, as well as cheapness are obtained by having the steam outside the coil, since only the coil is made of lead, the chamber and the coil supports being of iron or steel.—B. V. S.

Aldol; Process of making — N. Grünstein, Frankfurt, Germany. U.S. Pat. 1,231,156, July 24, 1917. Date of appl., Dec. 13, 1916.

ACETALDEHYDE, mixed with a little water, is treated with the oxide of an alkaline-earth metal, such as strontium oxide. The resulting solution is neutralised with acid and distilled *in vacuo*. —B. V. S.

Products of condensation [aldol]; Manufacture of — from acetaldehyde. N. Grünstein, Frankfurt, Germany. Eng. Pat. 101,636, Sept. 27, 1916. (Appl. No. 13,751 of 1916.) Under Int. Conv., Sept. 25, 1915.

SEE U.S. Pat. 1,234,156 of 1917; preceding. Alkaline-earth carbides may be added to serve as catalysts, and the reaction may be started with only part of the acetaldehyde, the remainder being added as the reaction proceeds.

Vitamine preparation; Highly active — thoroughly freed from inactive ingredients. A. Gams and B. Schreiber, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,235,198, July 31, 1917. Date of appl., Feb. 2, 1917.

ORGANIC food products are extracted with dilute alcohol and the alcohol removed from the extract by distillation *in vacuo*. The aqueous solution of the extract is treated successively in acid condition with lead acetate and in neutral condition with basic lead acetate for the removal of impurities. After freeing the solution from lead it may be evaporated to dryness, or may be first further purified by treatment with an alkaloid precipitant, decomposition of the precipitate, and re-solution of the alkaloid. The resulting vitamine products are yellowish-brown hygroscopic substances, soluble in water forming solutions feebly acid to litmus, and giving with alkalis yellow solutions with a strong smell of methylamine. The aqueous solutions give precipitates with tannin, silver nitrate, phosphomolybdic and phosphotungstic acids, the last of which gives characteristic colour reactions with sodium carbonate and diazobenzene-sulphonic acid.—B. V. S.

Medicament [antipyretic] and process of producing the same. A. D. Barr, McHuo, Ark. U.S. Pat. 1,235,278, July 31, 1917. Date of appl., Oct. 1, 1913.

A STIMULATING antipyretic is obtained by heating a solution of an aniline derivative containing the acetyl group, such as acetanilide (24.68%), with an organic acid, such as citric acid (36.56%), adding a vegetable alkaloid, such as caffeine (38.74%), heating and evaporating the solution, and crystallising the compound formed.—B. V. S.

Coca extracts: Process of preparing—F. R. Eldred, F. E. Bibbins, and R. N. Reed, Assignors to The Eli Lilly and Co., Indianapolis, Ind. U.S. Pat. 1,235,450, July 31, 1917. Date of appl. Feb. 5, 1917.

Coca leaves are steam distilled and then extracted with boiling water. The concentrated extract is treated with alcohol to remove ecgonine, benzoyl-ecgonine, and most of the cocaine, and the aqueous solution of the residue is treated with fuller's earth and filtered. The clear solution is concentrated and the extract mixed with the original distillate.—B. V. S.

Alcohols; Method of manufacturing polyvalent—O. Matter, Cologne, Germany. U.S. Pat. 1,237,076, Aug. 14, 1917. Date of appl. July 11, 1915.

POLYVALENT alcohols are produced by heating a chlorinated hydrocarbon in a closed vessel with a solution of an alkali carbonate and/or bicarbonate in presence of copper, the amount of water greatly exceeding that of the unaltered chlorinated hydrocarbon present.—F. W. A.

Tobacco; Method of dehydrating and curing—G. H. Benjamin, New York. Eng. Pat. 169,618, Apr. 4, 1917. (Appl. No. 1877 of 1917.)

SEE U.S. Pat. 1,224,703 of 1917; this J., 1917, 608. The temperatures stated should be read as degrees Fahrenheit instead of degrees centigrade.

Preparation of radioactive mineral waters containing radium-precipitating acids. Eng. Pat. 101,295. See VII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Photographic film. P. W. Lovejoy, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,232,702, July 10, 1917. Date of appl. Jan. 19, 1914.

THE base of the film consists of separate layers of two substances which develop respectively positive and negative electric charges when excited frictionally. For instance, a film of cellulose nitrate is coated on one side with a layer of mixed cellulose acetate and cellulose nitrate and on the other side with a light-sensitive film.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitro-derivatives of toluene; Preparation of—T. Kidokoro, Kogyo-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 460—480.

o-NITROTOLUENE is best prepared by addition of a mixture of 1 part nitric acid (sp. gr. 1.40) and 2 parts of sulphuric acid (sp. gr. 1.84) to 1 part of toluene, with stirring, at 30° C. for 6 hrs., the product being washed with water and dilute alkali, and distilled *in vacuo*; yield, 55.1% of theory. p-Nitrotoluene is obtained by nitration of 1 part of toluene with 2 parts of fuming nitric acid (sp. gr. 1.47) at the ordinary temperature for 15 hrs., purifying as described for the *ortho*-compound; yield 60% of theory. 2,4-Dinitrotoluene is prepared by addition of 110 c.c. of toluene to 230 c.c. of fuming nitric acid at the ordinary temperature, with stirring; the mixture is cooled, and 230 c.c. of sulphuric acid (sp. gr. 1.84) added; the mixture is warmed on a water-bath for 30 mins., poured on to ice, and the crystals of dinitrotoluene recrystallised from alcohol; yield, 98% of theory (m.pt. 71° C.). 2,4,6-Trinitrotoluene is obtained by

dissolving 40 grms. of dinitrotoluene in 88 c.c. of sulphuric acid (sp. gr. 1.84), adding 10 c.c. of nitric acid (sp. gr. 1.52), and heating the mixture for 1—5 hours on a water-bath until evolution of bubbles has ceased; yield, 96% of theory. Trinitro-*tert*.-butyltoluene (artificial musk) is prepared in the following stages: 50 grms. of strongly cooled butyl alcohol is saturated with dry hydrogen chloride and heated in a sealed glass tube for 24 hrs. at 100° C. giving 49 grms. of iso-butyl chloride; 50 grms. of toluene, 10 grms. of iso-butyl chloride, and 2 grms. of powdered aluminium chloride are heated for 1 hr. at the b.pt. of toluene, giving 16.61 grms. of *m-tert*.-butyltoluene; nitration of *m-tert*.-butyltoluene with a mixture of 1 part of 18% oleum and 2 parts of fuming nitric acid (sp. gr. 1.52) in 20 hrs. at 100° C. gives trinitro-*tert*.-butyltoluene (recryst. m.pt. 96°—97° C.). Certain reduction products of the above nitro-compounds are also dealt with.—F. W. A.

PATENTS.

Explosives; Process of drying—W. A. Phillips, Philadelphia, Pa., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,237,551, Aug. 21, 1917. Date of appl. Aug. 13, 1913.

Lubricant testing machine. J. W. Lowry, Chicago, U.S.A. Eng. Pat. 101,975, Oct. 25, 1916. (Appl. No. 15,202 of 1916.) Ender Int. Conv., Oct. 25, 1915.

THE lubricant to be tested is supplied to grooves in a bearing, in which a shaft is rotated at a known speed. The bearing may be divided horizontally and a predetermined load applied to the upper half, and an opening is provided for a thermometer. The shaft is rotated from driving pulleys through a clutch comprising two rings, carrying co-operating cam flanges. A spindle is held between the cam edges, and is forced axially against a resistance to a position depending on the pressure between the clutch members, due to the resistance opposed to the rotation of the shaft by the viscosity of the lubricant. The axial resistance to the movement of the spindle is provided by a pivoted stem, acting on a spring, and the movement is measured by the rotation of a pointer.—W. F. F.

[*Viscosity of fluids; Apparatus for ascertaining the properties*—W. M. Groszner, Ridge-wood, N.J., Assignor to Perkins Ghe Co. U.S. Pat. 1,236,706, Aug. 14, 1917. Date of appl. July 11, 1914.

THE liquid to be tested is placed in a removable cylindrical container supported on a constantly rotating turntable. A solid cylindrical body is suspended concentrically in the liquid by means

which measure the torsion exerted on the body by the rotation of the liquid. The bottom of the suspended body is recessed so as to enclose a volume of air to prevent contact of the liquid with the body except on the cylindrical surface.

—W. F. F.

Gases: Method of and apparatus for indicating the volumetric flow of—. E. E. Werner, St. Louis, Mo., U.S.A. Eng. Pat. 108,714, Aug. 14, 1916. (Appl. No. 11,473 of 1916.)

Gas to be measured is supplied through the pipe, 6, bulb, 5, and trap, 4, to the helically coiled tube, 2, sealed into the vessel, 1, containing liquid.

At the top of each coil, 7, a small orifice, 8, is provided through which bubbles of gas escape. The rate of flow of gas is measured by the number of orifices, 8, from which bubbles of gas are rising. The gas passes upward through a bulb, 11, for the collection of moisture, to the outlet, 15, where it may be mixed with air supplied by the pipe, 18.

the mixture passing out by the pipe, 19. The apparatus is particularly applicable for regulating the flow of gas used in bleaching flour. In a modification, the tube, 2, may be vertical and provided with successive enlargements along its length, each enlargement having an aperture in its upper surface. In another modification the tube, 2, may be straight but inclined, and provided with orifices along its upper wall.—W. F. F.

Trade Report.

MINERAL PRODUCTION OF CANADA IN 1916.

The accompanying statistics (subject to revision) of the mineral production of Canada during the year 1916 are taken from a preliminary report on the subject issued by the Canadian Department of Mines, Ottawa; the definitive figures for 1915 are added for purposes of comparison.

The value of the metal and mineral output of Canada last year was the highest yet recorded, the previous record being 145,634,812 dols. in 1913. As regards copper, it is notable that while the output increased by 18.8% in quantity as compared with 1915, the value increased by 87.1%. With the exception of a small production in experimental work, there was no recovery of zinc spelter or refined zinc in Canada prior to 1916. In 1915 the shipments of zinc ores to American smelters for reduction amounted to 14,895 tons, valued at 551,938 dols., and containing 12,231,439 lb. of zinc. Assuming a probable recovery of 80% of the metal, the production of zinc in 1915 from Canadian ores may be put at 9,785,151 lb., valued at 1,294,575 dols. Adding to the result of a similar estimate for 1916 the actual output of zinc at Trail, it would appear that the production of zinc from Canadian ores in that year was 23,515,030 lb., valued at 3,010,864 dols. According to the Report for 1916 of the British Columbian Minister of Mines, the output of zinc from the smelter at Trail in that year was approximately 15,000,000 lb. At the beginning of 1917 the output of the smelter was from 25 to 30 tons per day.

		1915.		1916.

Official Notices.

NEW MEMBERS OF COUNCIL.

At a Meeting of Council held on the 23rd October, the following gentlemen were elected Members of the Council to fill two vacancies which have occurred since the last Annual General Meeting:—

Mr. W. J. A. Butterfield, of London, in place of Professor H. E. Armstrong, F.R.S., resigned; and Mr. E. F. Hooper, of Stroud, Glos., in place of Mr. R. D. Pullar, deceased.

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council desires to remind intending competitors for the Cross and Bevan prize that Essays must be received at the offices of the Society before the close of the present year.

The Essay prize is open to all members of the Society who are British subjects. The Research Grant is limited to competitors under 25 years of age at the time of sending in the essay.

Full particulars were published in the issues of the Journal for 15th January and 15th and 28th February, 1917.

CENTRAL COMMITTEE ON SUPPLIES OF MATERIALS.

Dr. Addison, the Minister of Reconstruction, after consultation with other Government Departments concerned, has appointed a Committee to consider and report upon questions connected with the supplies of raw materials which will be required by British industries for the purpose of restoring and developing trade after the termination of the war, and the best means of securing and distributing supplies, due regard being had to the interests of the Allies. The Committee is requested, in regard to any commodities which might not be available in sufficient quantities and at reasonable prices through the ordinary commercial channels, to consult members of the trades concerned with regard to any steps that may be necessary to safeguard the needs of industry and to secure convenient and equitable distribution. The Committee, which will be known as the Central Committee on Supplies of Materials, consists of the following:—Sir Clarendon Hyde (Chairman), Sir Henry Birchenough, K.C.M.G.; Mr. Cecil Budd, Sir Charles W. Fielding, K.B.E., Sir H. Babington Smith, K.C.B., Mr. Wallace Thorneycroft, and Mr. Andrew Weir. The Secretary to the Committee is Mr. J. F. Ronca (Board of Trade), communications to whom should be addressed at the Ministry of Reconstruction, 2, Queen Anne's Gate Buildings, Westminster, London, S.W.1.

POTASSIUM COMPOUNDS.

MINISTRY OF MUNITIONS ORDER, OCT. 17TH, 1917.

The Minister of Munitions, in exercise of the powers conferred upon him by the Defence of the Realm Regulations and all other powers enabling him, hereby gives notice and orders as follows:—

1. No person shall as from the date hereof until further notice offer to purchase, purchase, or take delivery of any potassium compounds as defined in Clause 3 hereof except under and in accordance with the terms of a licence issued on behalf of the Minister of Munitions by the Controller of Potash Production, or offer to sell, sell, supply or deliver any such potassium compounds to any person other than the holder of such a licence and in accordance with the terms thereof

provided that no such licence shall be required (a) By the Admiralty or War Office. (b) By any person for the purchase and delivery of potassium compounds in quantities not exceeding in weight an aggregate of 3 lb. avoirdupois during any one calendar month.

2. All persons shall furnish returns to the Controller of Potash Production at the times and in the manner prescribed by him of all potassium compounds held in stock by them or otherwise under their control or manufactured, produced, bought, sold or otherwise dealt in by them.

3. The potassium compounds to which this order relates are caustic potash (KOH), chloride or muriate of potash (KCl), carbonate of potash (K_2CO_3), and sulphate of potash (K_2SO_4), whether in a pure or in a commercial form, and any material (other than blast furnace dust referred to in the Order of the Minister of Munitions of 7th August, 1917) of which more than 10% consists of any one or more of the above.

4. All applications in reference to the above Order to be addressed to The Controller of Potash Production, Ministry of Munitions, 117, Piccadilly, W.1.

MAXIMUM PRICES FIXED FOR COMPOUND FERTILISERS.

The Minister of Munitions has made an Order, dated 13th October, fixing maximum prices for sales of compound fertilisers. The Order took effect as from 17th October. The prices fixed are for sales during December, and reductions or increases in prices are to be made according as the month for delivery precedes or is subsequent to December. Schedules appended to the Order prescribe (1) the maximum unit rates authorised to be charged for specified constituents, and (2) the limits of error allowed in the invoice statement of the percentage of constituents which must be made in respect of each sale. These provisions do not apply to any sale of compound fertiliser for export from the United Kingdom.

The Order also requires persons producing and dealing in compound fertilisers to make such returns with regard to their businesses as may be required by the Minister of Munitions.

All applications in reference to this Order should be addressed to the Director of Acid Supplies, Ministry of Munitions, Department of Explosives Supply, Storey's Gate, Westminster, London, S.W.1., and marked "Fertilisers."

TAR OILS ORDER (see page 1110).

Edinburgh Section.

Meeting held at Edinburgh, on Tuesday, October 16th, 1917.

MR. D. B. DOTT IN THE CHAIR.

The CHAIRMAN gave a short address dealing with the teaching of science in schools, with special reference to recent reports and speeches on the subject.

THE UTILISATION OF FATTY ACIDS FOR FEEDING PURPOSES.

BY ALEX. LAUDER, D.S.C., F.I.C., AND T. W. FAGAN, M.A.

The great increase in the manufacture of glycerin during the last three years for the making of explosives has caused a corresponding increase in the production of fatty acids. As the amount produced is much in excess of what can ordinarily be utilised, the most suitable means of making

use of the increased production has frequently been under consideration.

During the early months of the present year, when there appeared to be every prospect of a serious food shortage, the possibility of utilising the free fatty acids to replace fat in feeding stuffs for cattle was considered.

The difficult question as to how fats are absorbed in the intestine has been the subject of much investigation and discussion. It is now held that the neutral fats are split in the intestine and the free fatty acids are in part absorbed in solution in the bile, and, in part, combined with alkalis to form soaps. After absorption, the neutral fats are regenerated again from the fatty acids. The soaps are also absorbed and decomposed, the alkali set free being secreted again into the intestine and used for the re-formation of soaps (Moore and Richmond, Hammersten's *Physiol. Chem.*, 1914, 536).

There does not appear to be, therefore, any reason from the physiological standpoint why free fatty acids should not be assimilated. The formation of fats from carbohydrates is now well established, and it appeared reasonable to conclude that an animal if supplied with a fatty acid should be able to convert it into a fat.

Munk (*Bied. Centr.*, 1881, 106) found that a dog fed with flesh and fatty acids from mutton suet deposited fat 96% of which had the same composition as ordinary suet. He consequently concluded that the fat had been formed from the fatty acids and not from the proteins, since the latter would have yielded dog fat. Experiments to test if the free fatty acids could be used to replace a certain amount of carbohydrates and fat in a ration were therefore undertaken with pigs.

Samples of various mixtures of fatty acids were obtained: these differed considerably in their average molecular weight and in the amount of unsaturated fatty acids which they contained.

The fatty acids from coconut oil were finally selected, not because the mixture was the most palatable or had the most agreeable smell, but because it could be obtained in sufficient amount without delay. The average molecular weight was 212 and the iodine value was 8.2.

The pig-feeding experiments were carried out by the kind permission of the Edinburgh District Board of Control, at the Bangour village farm, Dechmont, Linlithgowshire, where pigs from the well-known herd of "Large Whites" were placed at our disposal.

A preliminary experiment with 10 pigs was commenced on April 18th, 1917. These were divided into two lots of five each, but as the pigs varied considerably in age and weight it was not possible to get the lots sufficiently equal to enable very definite conclusions to be drawn.

The most suitable ration to feed along with the fatty acids was a question of some difficulty. It was desirable that it should have a low fat content, and owing to the restricted number of feeding stuffs available and to the fact that it was impossible to get potatoes, the choice was somewhat limited. Finally a mixture of equal parts of maize meal and sharps was selected for the ration for the control lot of pigs.

The average composition of maize meal and sharps is as under:—

	Maize meal.	Sharps.
	o/o	o/o
Proteins	10.5	15
Oil	5.0	4.5
Soluble carbohydrates	70.0	57.0
Crude fibre.....	2.0	8.0

For the other lot, about 5% of the weight fed was replaced by fatty acids, it being assumed

that the fatty acids were equivalent to 2.4 times their weight of carbohydrates. The "starch equivalent" of the mixture of maize meal and sharps was taken as 70. A weighed amount of green food was also used in addition.

This experiment was continued for four weeks, until a supply of young pigs, from which a better selection of animals could be obtained, was available. The fatty acids were melted in hot water and mixed with the meals; the pigs ate the mixture readily and made, as far as could be judged, quite as satisfactory live weight increases as the pigs in the control lot.

A more accurate experiment was commenced on May 7th, 1917, when 10 newly weaned young pigs, about seven weeks old, were carefully selected from a large number which were then available.

The weights of the two lots at the beginning of the experiment were as under:—

No.	Lot 1.	Lot 2.
	lb.	lb.
1	32.5	31.0
2	28.5	31.0
3	29.0	27.0
4	23.5	24.0
5	24.0	24.5
Total	137.5	137.5
Average	27.5	27.5

The following table shows the daily ration supplied for each lot of five pigs:—

Date.	Lot 1.	Lot 2.
	lb. meals.	5.25 lb. meals plus 5.0 oz. fatty acids.
1917.		
May 7	6.25	6.5
" 17	8.0	6.5
" 24	9.0	7.5
" 31	10.0	8.25
June 7	10.0	8.25
" 14	10.0	8.25
" 21	10.0	8.25
" 28	10.0	8.25
July 5	11.0	9.25
" 12	11.0	9.25
" 19	12.0	10.0

During the latter period of the experiment the pigs were given about 3 lb. cabbage per lot per day, in addition to the above rations as the diet was rather monotonous. The health of both lots of pigs was excellent and no difference could be detected between the lots in this respect.

The pigs were weighed in the morning and always, with one exception, in a fasting condition.

Pig No. 3 in Lot 2 never did well and was ill from time to time with some chest disease. It recovered to a certain extent as the experiment went on, but it will be noticed that it did not put on weight with the same regularity as the other pigs.

The pigs were weighed weekly; the table on p. 1071 shows the live weight increases obtained.

The results show that the increase in weight of the two lots is practically identical, and, as the amount of the ration was intentionally kept low, there can be no doubt that the fatty acids were assimilated and that they replaced about 2½ times their weight of carbohydrates. It had originally been intended to continue the feeding until the pigs were fat and to obtain specimens of their fat from the butcher after they had been killed in the ordinary way. By the end of July, however, neither lot was making the normal increase

Weight in pounds.

Lot 1 (Meals only).						Lot 2 (Meals and fatty acids).

Total increase: Lot 1=145.5 lb.

Lot 2=113.0 lb.

Notes.—(*) Interval of 10 days. (†) The pigs were fed before being weighed; this explains the abnormal gain in weight and the apparent low increase the following week. (‡) No. 3 ill.

in weight for pigs of their age, due probably to the great heat experienced about that time and to the monotony of the diet. It was therefore judged better to discontinue the experiment and put the pigs back to their ordinary diet.

We have to express our indebtedness to Professor James Walker, F.R.S., who suggested the experiment and who procured the necessary supplies of fatty acids for us.

We have also to express our thanks to Lt.-Colonel Keay, M.D., R.A.M.C., in command of Bangour Military Hospital, and to Mr. William Smith, Chairman of the Edinburgh District Board of Control, for the facilities afforded us in carrying out the experiment.

College of Agriculture,
Edinburgh.

Communications.

A NOTE ON THE CORROSION OF STEEL WATER PIPES.

BY A. B. BRADLEY.

During the last few months the writer has experienced considerable trouble arising from the corrosion of hydraulic steel pipes used in a deep well water service at Bermondsey. The water itself is of interest, being particularly hard when compared with other well waters from the immediate neighbourhood. The following is the average composition of the water, taken from 12 monthly analyses.

	Parts per 100,000.
Total solids	131.8
Calcium carbonate	32.6
Magnesium carbonate	8.0
Magnesium sulphate	19.7
Sodium sulphate	33.3
Sodium chloride	31.1
Sodium nitrate	0.82
Silica, iron oxide, etc.	1.72

Temporary hardness, 33; permanent hardness, 29.

The water when freshly pumped is perfectly clear, with a very slight smell of hydrogen sulphide, but, on standing for an hour or more, it becomes slightly turbid, with the evolution of gas. The water was found to be suitable for domestic purposes from a bacteriological point of view, and was in use in the factory for nearly all purposes (boilers excepted). The service had been working for about four years without com-

plaint, when suddenly considerable trouble arose through the raising main, which conveyed the water from the pump house to the main supply tank at the top of a block of buildings becoming perforated. The pipes in question were hydraulic steel tubes 6 in. and 4 in. bore, having a wall thickness of $\frac{3}{8}$ in. to $\frac{1}{2}$ in. In every case where a perforation was found the pipe was in a horizontal position, and the perforation always formed at the top. On cutting sections through a defective pipe the steel was found to have been eaten away the whole length, a channel having been formed about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. wide; leaving the steel wall of the tube about $\frac{1}{8}$ in. thick at the top. Several perforations have formed on a single length of pipe at different times. This defect was thought to be so serious that efforts were made to ascertain the cause. Glass cylinders of 2000 c.c. capacity were filled with freshly pumped well water and left in a horizontal position, continuous observation being made. After a short time, minute bubbles of gas were seen to have formed on the surface of the cylinder and gradually rose to the top, so that after about an hour a continuous string of bubbles had formed the whole length of the cylinder. After standing for 12 hours, 6.2 c.c. of gas had been evolved from 2000 c.c. of well water. The gas was found to consist chiefly of carbon dioxide, with a small amount of hydrogen sulphide. Carbon dioxide, as is well known, readily attacks most metals in the presence of moisture, so that this suggested itself as the cause of the trouble. Two perfectly bright weighed steel rods were placed in a 2000 c.c. cylinder filled with freshly pumped well water, in such a position that one was at the bottom covered with water, the other being fixed at the top so as to be in contact with any gas evolved. After a few hours both rods were seen to have been attacked, the top much more vigorously than the bottom one. After 100 hours' contact both rods were taken out, carefully wiped dry, and weighed. The top rod was found to have lost 0.6% of its weight, and the bottom one 0.16%. Microscopically the bottom rod was observed to be perfectly even on the surface and of a dull grey colour, as if a film of sulphide had formed, whereas the top rod was seen to have been eaten quite badly, almost the whole surface being etched quite deeply. Cast iron elbows used in the service, when in a horizontal position, were found to be in almost perfect condition, except where the thread had been cut into them, the water thus coming into contact with the soft under metal, the hard surface metal being unaffected.

The conclusion arrived at was therefore as follows:—The action of pumping water highly charged with carbonates and carbon dioxide liberates some of the gas which, so long as it is being driven through the pipes, is carried upwards with the water, but as soon as pumping ceases the gas rises to the top of the horizontal sections, where it has free play on the metal until driven off by the next pumping. It should be mentioned that pumping is not continuous, the supply tank being fed to overflow when pumping ceases. No trouble has been experienced with pipes which lead from the supply tank, most of the free gas having escaped. A perfect coating of pitch or similar material should protect the pipes, and this experiment is being carried out; pipes thus treated are to be examined at yearly intervals. If the pipes were laid out of the horizontal in such a manner that the gas rose to a common angle joint as soon as formed, a greater part of the trouble could doubtless be overcome, the gas being removed from the angles through a small tap.

VULCANISATION CATALYSTS.

BY D. F. TWISS.

Under the above heading (this Journal, 1917, 950) Mr. S. J. Peachey has recently made reference to my paper on the "Chemistry of Vulcanisation" (this J., 1917, 782) and suggests that this "is likely to give rise to an erroneous impression that basicity is an invariable concomitant of accelerating power."

Such an impression was far from intended, as indeed is indicated by my statement "*almost* the whole of the known effective organic accelerators are basic" (p. 780). My investigations in this direction have not been restricted to a working theory that basicity is essential in an accelerator, but the fact that strongly basic substances generally appear capable of exerting an accelerating effect on vulcanisation is suggestive of a common mode of action for this class of vulcanisation catalyst; the consideration of the mechanism of acceleration given on p. 787 was therefore definitely restricted to the case of basic accelerators.

Experiments which I have made with nitroso-compounds as vulcanisation catalysts have not been limited to those containing also an amino-group, but *p*-nitrosodimethylaniline, being the first discovered and also, as Mr. Peachey agrees, probably the most effective, may be regarded as the best example of the nitroso-class. In my paper, results were given showing that *p*-nitrosodimethylaniline is much inferior to some of the strongest of the basic accelerators (organic or inorganic) and my statement (p. 787) that "the nitroso-compound is much more effective in mixings containing a high percentage of sulphur . . . and that mixings . . . with a low percentage of free sulphur have been found to behave less satisfactorily with the nitroso-compound" serves to emphasise this point. It is certainly most desirable that investigations of the acceleration of vulcanisation should be made in as many different directions as possible especially because, in our present state of knowledge, there appears to be no satisfactory explanation as to the manner in which the effect is produced.

Mr. Peachey's fear lest my paper should impart the idea that only basic vulcanisation catalysts exist will, I hope, prove to be without justification. It is, however, my decided opinion, the grounds for which are not restricted to published experimental results, that no known accelerator of the nitroso-type nearly approaches in activity the best basic accelerators.

Institute of Metals.

The Autumn Meeting of the Institute of Metals, held under the presidency of Sir George Beilby in the rooms of the Chemical Society on September 19th, proved to be of great interest. Dr. Haigh's paper on the fatigue of brasses described experiments with an alternating stress machine, in which the stress, produced by electro-magnetic means, varies in a perfectly regular manner according to a sine curve, so that the experimental conditions may be reproduced exactly with different metals, and an exact comparison with the resistance to static stresses may be made. Among the observations which attracted attention in the discussion was the influence of corroding agents, such as ammonia, in reducing the resistance to alternating stresses. The effect of comparatively small surface scratches in starting failure by fatigue was also well shown, indicating the desirability of polishing machine parts subject to alternating stress. Prof. Turner raised the general question of the nature of hardness and of the mechanism of hardening by cold work, and in the course of a review of the subject, expressed the opinion that the increased rigidity of a work-hardened metal is due to the existence of tension in the films of amorphous material which, as shown by the President, are formed at the internal surfaces on which slipping has taken place during deformation. The discussion turned largely on the terms employed, it being well known that different methods of determining hardness do not really measure the same property. The numerous experiments on the softening of cold-rolled aluminium sheet by heat, described by Prof. Carpenter and Mr. Taverner, showed that whilst softening was very rapid at temperatures above 300° C., the tenacity of the annealed metal being independent of the temperature of annealing, it took place much more slowly as the temperature was reduced, and it was not yet quite clear whether the same final value would be obtained, say, at 100° C., if the heating were continued for a sufficiently long time. The fact of an actual rise in tenacity at one stage of the annealing process was observed, and its meaning discussed. The President pointed out that the absolute dimensions of the metal were of importance in such low-temperature annealing experiments, thin wires behaving quite differently from larger masses. Other speakers discussed the influence of the impurities in commercial aluminium, silicon especially having an important effect in modifying the softening. A note by Prof. Jeffries, which was taken as read, disposed of a statement by Hanriot, which has been accepted in many quarters, to the effect that permanent hardening may be produced by uniform hydrostatic pressure. The source of the error was shown, and new experiments described to prove that hardening only occurs where there is deformation, this view being in accordance with Beilby's hypothesis.

The evening session was devoted to a further discussion of some of the problems of metal melting, which had aroused such a lively interest at the Spring Meeting. Mr. Ionides had arranged a demonstration of his new system of gas-firing, and the lecture table was occupied by an elaborate installation of burners, measuring instruments, and furnace equipment. A hot and steady flame was produced, using air under pressure and the ordinary gas supply. It was not easy to understand from the paper the exact nature of the new method, but Dr. Harker, in opening the discussion, showed that the principle was that of burning an explosive mixture of gas and air in such a way as to prevent firing back, the ratio of gas to air being maintained constant, in spite of accidental

variations in the supply, by an ingenious and delicate pressure balance. Figures were given showing the efficiency of the system as applied to melting and billet heating furnaces, but the figures of gas consumption by other systems given for comparison aroused much discussion, several of the speakers claiming that equally good results were obtained from gas furnaces of different types. This point led to a lively controversy, and it will be interesting to compare the experimental data furnished by the speakers concerning the systems of which they had personal experience, when the printed record of the discussion appears. The second paper, by Mr. Harvey, dealt with fuel economy in brass melting, and gave many figures, the author's preference being for firing by means of powdered coal, but this opinion was not shared by subsequent speakers. Among other objections, the use of powdered raw coal does not overcome the difficulty of the loss of by-products, which is inevitable in any system which does not provide for a partial or complete gasification of the raw coal. However, the paper also contained useful suggestions as to the improvement of efficiency in gas-heated brass furnaces. Taken together with the discussion at the Spring Meeting, the series of papers on metal melting contributed to the Institute form an invaluable source of information on this important subject.

It was announced that Prof. Carpenter, of the Imperial College of Science and Technology, had been chosen as the next President of the Institute.

Abstracts of the papers read at this meeting will be found in this Journal, 1917, pp. 1051 and 1097-1099.

Industrial Notes.

DEVELOPMENT OF IMPORTANT CHEMICAL INDUSTRIES IN RELATION TO THE WAR.

The following is a summary of a paper by Prof. E. Molineri, in *Annali di Chimica Applicata*, 1917, 8, 13-41.

Sulphuric acid.—Prior to the war Italy produced about 318,000 tons of sulphuric acid, about 80% of which was used in the manufacture of superphosphate, and only about 18,000 tons for explosives. In France about 70,000 tons, and in Germany and Austria about 300,000 tons were used in the manufacture of explosives. In 1916 Italy consumed over 160,000 tons for explosives; France not less than 1 million tons; England about 800,000 tons; Russia and other allied countries about 500,000 tons; whilst Germany and Austria must have used at least 2 million tons. In Germany the pyrites used in the manufacture is utilised efficiently, the cinder containing not more than 0.8 to 1% sulphur, and the leaden chambers produce up to 10 kilos. of sulphuric acid per cb. m. of space in 24 hours, whereas in Italian works the pyrites cinder contains 3 to 4% of sulphur, and the output of acid does not reach more than 4 to 5 kilos. per cb. m. A new process has recently been introduced in Germany, in which calcium sulphate is heated to a high temperature in a suitable furnace in the presence of silica and bisulphate (nitro cake). In Italy and France the difficulty of increasing the output is due to want of plant and not, as in Germany, to insufficient material.

Nitric acid.—In peace time Germany annually imported about 800,000 tons of sodium nitrate, about 80% of which was intended for artificial manures, and only about 20% used in chemical industries, chiefly for the manufacture of nitric

acid. The amount of nitrate used by the other nations in chemical industry varied from 10 to 15% of their imports of nitrate. The estimated consumption of nitric acid by Germany in 1915 is 500,000 tons. It has been established that to fix 1 kilo. of atmospheric nitrogen in the form of nitrate or nitric acid Pauling's process, established at Innsbrück, requires 70 kilowatts per hour, the Birkeland-Eyde process 60 kilowatts, and Schönherr's process, applied by the Badische Anilin und Soda Fabrik, 58 kilowatts. Pauling's process has been adopted in works in Rome and elsewhere in Italy. The nitric acid thus obtained requires concentration before it can be used in the manufacture of explosives. Prior to the war, Germany produced about 150,000 tons of ammonia from the distillation of about 40 million tons of coal, and this output has probably been doubled by now. Formerly, only about 1800 tons of calcium cyanamide was produced in Germany, whereas in 1916 the output reached 450,000 tons. To this may be added the ammonia recovered by the Mond process from coal dust, lignite, and peat, and that obtained by direct synthesis from atmospheric nitrogen and hydrogen by the process of Haber and Rossignol. In England, ammonia is now oxidised on a large scale by the Kuhlmann-Ostwald process; and a large plant has been put up at Angoulême (France), which produces 10,000 kilos. of concentrated nitric acid per day.

Distillation of coal.—The amounts of coal distilled for gas or metallurgical coke in 1910 were as follows:—United States, 60 million; Germany, 40 millions; England, 46 million; Russia, 5 million; Belgium, 4 million; France, 8 million; Austria, 4½ million; and Italy, 1.4 million tons. By distillation of all the coal tar then obtained throughout the world there would be at most an output of 100,000 tons of crude benzene and toluene, whilst by recovering the benzene and toluene from the illuminating gas it would have been possible to produce 1,700,000 tons. Coke ovens with plant for recovering benzene accounted for only 5% of the possible yield in 1900, and 16% in 1909 in the United States. In England, the corresponding figures were 10% in 1900, and 28% in 1909; whilst in Germany the output increased from 10% in 1900 to 82% in 1909. Phenol and picric acid are now prepared synthetically from benzene, by processes which had not been found suitable in times of peace. Benzene is treated with chlorine in presence of iron as catalyst, and the monochlorobenzene is nitrated and the product saponified; or, benzene is sulphonated, the sodium salt of the resulting benzenesulphonic acid fused with caustic soda to produce phenol, which is then nitrated to obtain picric acid. Picric acid thus manufactured in England, France, and Italy, furnishes the greater proportion of the explosives used in the war. In Italy alone, one plant produces 16,000 kilos. of synthetic phenol per day from pure benzene obtained from Italian coal and from light tar oils imported from England. From 50,000 to 60,000 kilos. of picric acid is produced daily by various factories in England by means of these processes, whilst, in France, the Soc. Usines du Rhône now produces daily up to 150,000 kilos. of phenol for the manufacture of picric acid. Other factories in France produce from 30,000 to 50,000 kilos. per day; whilst others, again, produce immense quantities of dinitrophenol. It is estimated that during 1916 approximately 1,805,000 tons of explosives was produced throughout the world, the chief consuming countries being as follows:—England, 200,000; Germany, 540,000; France, 300,000; Italy, 45,000; United States, 160,000; Russia, 100,000; Japan, 90,000; and Austria, 150,000 tons.

Dyestuffs.—In 1911 Italy imported 6823 tons of coal tar dyestuffs and derivatives, and in 1913.

7663 tons. Owing to the war, the conditions are now changed, and the existing plant in Italy is capable of producing 12,000 tons of pure benzene, and 2000 tons of toluene per annum, in addition to 560 tons of phenol, about 3000 tons of naphthalene, and 560 tons of anthracene. These quantities should be sufficient to meet any future demand for dyestuffs in Italy.—C. A. M.

REPORT OF THE FUEL RESEARCH BOARD.

The Fuel Research Board has presented to the Committee of the Privy Council for Scientific and Industrial Research a report on their scheme of research and on the establishment of a fuel research station.

In their First Report (which was not published) the Board stated that they had in view two main lines of research: First, a survey and classification of the coal seams in the various mining districts by means of chemical and physical tests in the laboratory, and, second, an investigation of the practical problems which must be solved if any large proportion of the raw coal at present burned in its natural state is to be replaced by the various forms of fuel obtainable from coal by carbonisation and gasification processes.

In preparation for the organisation of the first line of enquiry, an experimental study of standard methods for the examination of samples of coal in the laboratory has been made. Hitherto in the systematic examination of coals in the laboratory there has been no generally accepted low-temperature carbonisation test. Certain existing tests are designed to ascertain the suitability of coal for gas or coke making, but as both these methods of carbonisation are carried out at temperatures above 900° C. they give little or no direct information as to the behaviour of the coal when carbonised at 500° to 600° C.

A test has been elaborated which by direct weighing and measurement gives the yields of gas, oil, water, and carbonaceous residue which result from carbonisation at any definite temperature. The apparatus is simple and is so arranged that the progress of the distillation can be watched from start to finish. The products can be weighed or measured with reasonable accuracy, and any or all of them can, if desired, be submitted to further examination. The method has been tested on certain typical coals and at a variety of temperatures, but before publishing the results it is proposed to make further tests with a wider range of samples.

It is not proposed to start any extensive organisation for the collection and registration of samples till the preparations for the second line of enquiry are further advanced.

The gas retort and the coke oven have become highly developed appliances for the carbonisation of coal at temperatures ranging from 900° to 1200° C. In the former the primary object of the carbonisation is to obtain the maximum yield of gas suitable for domestic and industrial lighting and heating, while in the latter coke is regarded as the principal product. In considering the broad question of the replacement of any considerable proportion of the coal which is at present being burned in its raw or natural state by manufactured forms of fuel, the part which may be played by high temperature methods of carbonisation will need to be taken into account. For this purpose a great amount of experience is available, and trustworthy data on which to base the calculation of the economic possibilities are in existence.

The distillation of oil shales at low temperatures for the production of mineral oils, paraffin wax, and ammonia is a highly developed industry, but

the oil shales are totally unlike coal in their nature and in the products which they yield so that the experience gained in this industry, though undoubtedly valuable, is only indirectly useful so far as coal is concerned.

As regards the carbonisation of coal at low temperatures there is no corresponding body of experience in existence and there are very few properly accredited data available. Some work has been done by individual inventors and syndicates and a certain amount of experience has been gained. While only portions of this experience have been disclosed enough is known to justify the conclusion that much still remains to be done in devising the special forms of apparatus required for the economical carrying out of this type of carbonisation.

The way is clearly open for a serious attempt to determine whether an economical and efficient apparatus can be devised for the carbonisation of coal at low temperatures and whether, by the use of such an apparatus for the carbonisation of properly selected coals, products will be obtained of a collective value greater than that of the original coal plus the cost of carbonisation and handling. Obviously the evolution of an economical and efficient apparatus is at the root of the whole matter, for only after a thoroughly practical apparatus is available can trustworthy tests of the various classes of coal be made and the economic possibilities of the method be fully weighed and considered.

The solution of these fundamental problems will supply a new base from which to attack questions like the following:—

(1) Can the 35 to 40 million tons of raw coal which is used every year for domestic heating be wholly or partially replaced by smokeless fuel, solid and gaseous, prepared by the carbonisation of this coal?

(2) Can adequate supplies of fuel oil for the Navy be obtained by carbonisation of the coal which is at present used in its raw form for industrial and domestic purposes?

(3) Can supplies of town gas be obtained more economically and conveniently by methods of carbonisation and gasification other than those at present in use in gas-works?

(4) Can electric power be obtained more cheaply if the coal used for steam raising is first subjected to processes of carbonisation and gasification?

(5) Will the more scientific development of the preparation and use of fuel, which would be implied in the successful working out of the foregoing questions, enable the peat deposits of the United Kingdom to take a serious place as economic sources of fuel for industrial purposes?

(6) Can the use of gaseous fuel in industrial operations be forwarded by the development of more scientific methods of combustion in furnaces, muffles, and ovens used in metallurgical, ceramic, and chemical operations?

The answers to these questions will only be obtained by co-ordinated research carried out on the lines of a broad and well-considered scheme. The subjects to be dealt with are already attracting the attention of serious workers in the industries, and it is to be expected that solutions of some of the problems will be supplied by these workers. The Board sincerely hope that this will be the case. They would regard it as a great misfortune if the establishment of a Government organisation for Fuel Research were to result in the discouragement or limitation in any way of the activities of outside workers or organisations. They venture to hope rather that many of these workers will be disposed to welcome a national scheme of research, the aims of which are broad and yet definite and in which the more specialised contributions from all sides will naturally take their place.

In considering new and extensive schemes of carbonisation it is necessary to bear in mind that outlets for all the products of carbonisation must be found. The gas, coke and shale oil industries are all of old standing and each has had to develop outlets for its products by patient and continuous effort. No new carbonisation scheme can be justified economically if it can only live by poaching on the preserves of the existing industries. Even if an efficient method of low temperature carbonisation is evolved it will be valueless in the wider sense unless profitable outlets for all the important products can be developed. It is obvious that the Fuel Research Board, which is in official touch with the Admiralty, the Ministry of Munitions, the Board of Trade, and other public Departments, is exceptionally placed for the furtherance of schemes which involve the finding of large outlets for products new and old. It is known for instance that the Admiralty attach great importance to the development of supplies of fuel oil from home sources, so that it may be taken for granted that this requirement alone would absorb all the oil which could be produced by the carbonisation of tens of millions of tons of coal per annum. This fact alone gives an entirely new aspect to the extension of carbonisation in hitherto untried directions, but while it will undoubtedly help on the economic side of the problem it in no way relieves the pressure on the technical side. In a way, moreover, it accentuates the problem now to be referred to, the profitable disposal of the coke or carbonaceous residue left when the volatile products are distilled from the coal. The percentage of coke obtained varies with the quality of the coal and the temperature at which it is carbonised, but it may be taken on the average that each ton of coal carbonised will give about 15 cwt. of coke. Thus to obtain one million tons of fuel oil for the Navy it would be necessary to carbonise twenty million tons of coal, and the coke produced would amount to 15 million tons.

The disposal of this very large quantity of coke or char at a profitable price must be regarded as the vital question if low temperature carbonisation is to be established on a sound economic basis. The research scheme must therefore include a very complete enquiry on three main lines:—

(1) The use and value of this coke for the direct firing of steam boilers.

(2) Its gasification in producers for the manufacture of low-grade fuel gas and the recovery of its nitrogen as ammonia.

(3) Its use for industrial and domestic heating either directly, as it comes from the retorts, or after its conversion into briquettes.

The second of these enquiries will involve the development of a special form of gas producer and auxiliary plant if the best results are to be obtained from the coke. It will also involve the development of a system of boiler firing in which fuel gas of 130 B.T.U. can be burned at least as efficiently as coal both as regards thermal efficiency and the effective evaporation per square foot of heating surface.

In all that concerns the preparation and use of special forms of fuel there are two distinct stages of development to be successfully passed. In the first stage apparatus and methods have to be evolved and tested till a practical standard of efficiency is reached. In the second stage the consumers of fuel must be induced to study the new apparatus and methods till they thoroughly understand and in the end adopt them. This second stage will be most readily passed, if an expert staff trained at a fuel research station is available to undertake the education of those who desire to adopt the new methods and appliances.

The use of town gas as a fuel for industrial purposes has made great strides during the past

few years and a number of experts are to-day engaged on the design and adaptation of furnaces and apparatus for these purposes. The actual practice of gas-heating still lags a long way behind the ideals of economy and efficiency and there is room for much useful experimental enquiry into principles and methods.

The use of the lower grades of fuel gas, though successfully carried out in certain directions, is very imperfectly understood in the majority of industries in which gas might be used for heating and power purposes. In this direction there is scope for much useful work both in research and in the education of experts and consumers.

A single illustration may be given of the complicated enquiries which will have to be conducted before an answer can be given to what seems to be a simple question.

There is a very general belief among electrical experts that the future of British industry will be greatly affected by the cost at which power in bulk can be supplied in the form of electricity. It has been proposed, for instance, that large electro-chemical works should be established in this country for the manufacture of products which in the past have been manufactured in parts of the world where cheap water power is available. In this connection it has been suggested that the cost of producing power from coal in this country would be substantially reduced if instead of burning the coal directly under the steam boilers it were first subjected to carbonisation and gasification processes which in addition to fuel gas would yield valuable by-products. Plausible statements have been issued showing the enormous savings or profits which would accrue if schemes of this sort were adopted. Unfortunately these estimates have generally been made on a very slender foundation of knowledge and experience. On the other hand those who by experience and practice are best qualified to judge, hesitate to prophesy as to what the economic result of a combined carbonisation and power generating scheme would be, but they agree that the interests at stake are so great that the question ought to be authoritatively answered once for all. But no answer can be accepted which is not founded on the complete working out of the scheme, no important step in the series of operations being omitted or slurred over. This series of operations will start from the mechanical preparation of the coal and its conversion into solid, liquid and gaseous products by carbonisation. It will end with the delivery of a known weight of high-pressure steam under the conditions most favourable for power production by turbo-generators. In the proposed scheme of research it will be seen that the investigation of each of the steps involved in the above enquiry is provided for. Three, at least, of these steps involve pioneering work on an industrial scale and the work may occupy a considerable time. The Board realise that it is possible that the net result of this particular enquiry may be to show that purely as a means of cheapening the cost of electric power the use of carbonisation methods has not much to commend it, but that certain incidental advantages will justify its use in particular cases.

Fuel research station.

The scheme of research which has been outlined in this Report can only be efficiently carried out in a Fuel Research Station designed and equipped for the purpose in which operations on an industrial scale can be carried out under proper working conditions. A description is given of the equipment which will be required for the research work at present in view.

It was realised that the Research Station should be situated in the neighbourhood of a large gas works, and Dr. Charles Carpenter, on behalf of

the Board of the South Metropolitan Gas Company, has made the following very generous offer to this Board: (1) To lease to the Government at a peppercorn rent sufficient land at the East Greenwich Gas-Works for the erection of a Research Station, (2) to prepare drawings and specifications for this station on lines to be laid down by this Board, and to make contracts for its erection, (3) to give every facility for the transport of coal and other supplies to the Station and to take over at market prices the surplus products, gas, tar, liquor, and coke resulting from the operations at the Station. The proposed site is a strip of level ground about 250 feet wide by 700 to 800 feet long situated on the main siding which connects the gas-works with the South-Eastern Railway and with access to an existing road.

The foregoing scheme of research is obviously not intended to cover the whole of the territory which is open for exploration to-day. Still less ought it to be regarded as setting any limits to the exploration of new territories in the future. The root idea of the scheme is that certain fundamental changes in the preparation and use of fuel which have been proposed are of such far-reaching importance that the solution of the technical and economic problems involved ought to take precedence of all other matters. This does not mean that other lines of research will be ignored, but only that the larger issues must be kept well to the front till definite solutions of those technical and economic problems can be given. Though no direct reference has been made to the preparation and use of fuels from oil shales, brown coals, and peat, it is obvious that experimental enquiries on these matters will naturally find a place in the developments of the present scheme.

The Research Station, as planned, will be capable of any extensions which will be required for future researches. Out of the four acres which it is proposed to lease for the Station, only one acre will be occupied by buildings under the present scheme. Further, a large part of the equipment of these buildings will be of a permanent character and will serve all the general purposes of a Research Station. Future extensions will, therefore, not repeat this permanent equipment but will be based upon it.

COMMONWEALTH ADVISORY COUNCIL OF SCIENCE AND INDUSTRY.

The Executive Committee of the Australian Advisory Council of Science and Industry has issued a report of its work covering the period from the date of appointment (Apr. 14, 1916 to June 30, 1917).

In the introductory part the constitution of the Committee and the policy and nature of its work are outlined, and a list of the Special Committees appointed is given.

Agricultural and pastoral industries.

Attention has been given to numerous questions concerning the control and eradication of pests and diseases of stock and crops and to the cultivation of new or improved crops. In connection with flax cultivation, mention is made of a new process of chemical retting in which an extract of linseed is used. The subject of cotton cultivation is considered at some length. Mention is also made of the desirability of a systematic soil survey of the Commonwealth.

Forest and vegetable products.

Wood-pulp. As far as the Committee have been able to ascertain, the only plant erected in Australia for the manufacture of wood-pulp is

that belonging to the Queensland Pine Co., Ltd., at Yarraman Creek. At this mill hoop pine (*Arucaria cunninghami*) and bunya bunya (*A. bidwilli*) were treated by the sulphate process, and a good type of wood-pulp prepared, which obtained a ready sale. The mill had to close down in 1916 owing to lack of water, and has not been reopened. The company state that some form of assistance to the enterprise by the Federal Government would be necessary to induce them to re-start operations. Some years ago the Australian Paper Mills Co. prepared some excellent wood-pulp, utilising the filamentary waste of the mountain-ash (*Eucalyptus regnans*). The Queensland Pine Co. experimented with ironbark, spotted-gum, crowfoot, and yellow-wood, and found them unsuitable.

Destructive distillation. Messrs. Cuming, Smith, and Co.'s works at Yarra Junction, Victoria, and Mr. J. V. Vale's works at Wyee, New South Wales, are at present the only works in Australia distilling timber, as far as the Committee can ascertain. The former firm's works have been in operation for a number of years, during which they have distilled all available eucalyptus timbers, and they report that the yield from all the species is very similar. There are, however, certain difficulties in treating eucalypts which are not present in the case of European and American hardwoods, and a serious obstacle to the development of the industry is the lack of markets in Australia for many of the chemical products of distillation and the comparatively small demand for charcoal. Mr. Vale's works have only recently commenced operations, and have at present dealt with swamp oak (*Casuarina glauca*), the yield from which is satisfactory. The New South Wales Forestry Commission has arranged with Mr. Vale to have tests made on 1-ton samples of about 30 other timbers. In the so-called myrtle (*Fagus cunninghami*) of Tasmania and Victoria, Australia possesses a true beech closely akin to the beeches of Europe and America, whose timber is one of the main raw materials used in those countries in the distillation industry.

Sources of tannin. The supply of tan-bark for use in Australian tanneries has for many years past been obtained mainly from two species of wattle—the golden wattle (*Acacia pycnantha*) of South Australia, and the black or green wattle (*A. decurrens*) and its varieties. As a result of the gradual destruction of wattle-trees the Australian supply has become inadequate, and has been largely supplemented by wattle-bark imported from Natal, where plantations have been formed by the utilisation of Australian seed. Owing to the cheap labour available in South Africa, and the fact that the wood from the wattles is in demand for firewood in that country, where timber is scarce, there seems little chance of Australia being able to compete with Natal in the production of wattle-bark. In addition to the wattles, a valuable tan-bark is yielded by the mallet (*Eucalyptus occidentalis*) of Western Australia, but though the useful properties of this bark were only discovered in 1903, its exploitation was so rapid that only comparatively small quantities now remain. Four possible means have been suggested to insure a local supply of tannin for the future, viz.: (1) Regulation of bark collecting to prevent the destruction of young trees, and thus secure the maximum amount of bark. (2) Plantation of wattles for the production of bark. Many such plantations were formed some 30 years ago, but owing to the slow growth of the trees and the great danger from bush-fires, wattle-plantations are not successful in Australia. (3) Discovery of new sources of tannin. Barks of about 150 species of Australian trees have been analysed as to their tannin content, and fifteen have been found to average over 20% of tannin.

Of these, nine are wattles, but, except for the two species already mentioned, they are not very abundant trees, though some of them are utilised locally to some extent. Two are cypress-pines, and one of these (*Callitris calcarata*) is a plentiful tree in Eastern Australia, and is utilised to some extent. Three are mangroves, but the bark from these trees has hitherto not been utilised to any extent in Australia, owing to the fact that mangrove-bark contains a dye which gives a red colour to the leather. The Executive has appointed a Special Committee to consider the best means of utilising the bark and possible methods for decolorising the tan-liquors obtained from it. The remaining species is the mallet, already referred to. In addition, the kino (gum) produced by the redgum of Western Australia (*Eucalyptus calophylla*) contains a high percentage of tannin, which is also present in the kino-saturated portions of the bark. As in the case of the mangrove, a dye is also present which stains the leather a red colour, and largely prevents the use of this bark for tanning purposes. The redgum is a very abundant tree in Western Australia, and the Executive has appointed a Special Committee to investigate the whole question. (1) Manufacture of tannin extracts. This is perhaps the most promising solution of the shortage of tanning materials, as it allows of the utilisation of leaves, twigs, etc., as well as of barks containing too little tannin to be used directly. It would be a means of avoiding the great amount of waste involved in the present methods of collecting wattle-bark, in which the tree is cut down and the bark stripped from the trunk whilst the smaller branches and twigs are not utilised. Extracts have been prepared from wattle-twigs, etc., by several Australian firms, but one of the difficulties is that gums and dyes are also extracted in the process, and the extracts have to be decolorised, whilst the presence of the gums is detrimental. Before the war large quantities of Australian barks, including those of wattle, mallet, and mangrove, were utilised in Germany for the production of extracts, and these German extracts were imported into Australia. Chemical research in Germany had solved the problems of decolorisation and of the removal of undesirable gummy matter, and these problems should be investigated in Australia.

Other vegetable extracts.—The Executive Committee has received numerous suggestions as to possible methods of utilising several native Australian vegetable substances. A number of correspondents have prepared dyes of brown and khaki shades from mangrove bark, and similar dyes have been prepared from the resin of the grass-tree and from eucalyptus barks, and the investigation of native plants, with a view to their utilisation as sources of dyes, is being carried on at the Technological Museum, Sydney. The camphor-laurel (*Cinnamomum camphora*) is commonly cultivated in Queensland, and it was suggested that it might be utilised for the production of camphor. A native Queensland tree known as the sassafras (*Cinnamomum oliveri*) has also been shown to contain camphor. A special committee in Queensland is making an investigation of this question. A committee has also been appointed to investigate the chemical composition of grass-tree (*Xanthorrhoea*) resins.

Mining and metallurgy.

There is wide scope in Australia for investigational work, with a view to developing new or improved processes, especially for the treatment of low-grade ores, and determining the properties of various alloys. One of the matters originally suggested to the Committee as requiring immediate consideration was the question of the best means of extraction of zinc from its ores, with special

reference to the electrolytic process. Since the Committee was formed, however, the Amalgamated Zinc Co. have taken up the problem of the electrolytic extraction of zinc, and as a result, the Electrolytic Zinc Co. has been formed and has made arrangements for carrying it out on a large scale.

Another matter suggested for early consideration was the production of ferro-alloys for high-speed steel. Research on this problem had already been begun by Messrs. A. J. Higgins and E. B. Brown at Melbourne University, under the auspices of the Federal Munitions Committee, and a request was received from that body that further financial assistance for this work might be given by the Advisory Council. This was granted, and the work has since proceeded as a research by a Special Committee of the Advisory Council. Up to the present the work has been confined to investigations of the manufacture of ferro-chrome and ferro-tungsten. The experiments on the manufacture of ferro-chrome prove that there is no difficulty in manufacturing this alloy at a reasonable cost, providing a sufficiently cheap source of electric supply is available. Ferro-tungsten has presented more difficulties, and the Committee is not yet able to give final conclusions as to the best method to adopt in its manufacture. A very pure alloy has been made by the reduction of wolfram ore with carbon in the electric furnace, but the yield was very low, owing to the fact that the ore contains manganese and that a prolonged treatment was necessary in order to volatilise that impurity. A number of experiments have been made with charges of wolfram ore and carbon, with a view to ascertaining whether it would be possible to produce a pure alloy direct from the ore without an excessive loss of tungsten. The Committee has succeeded in reducing the loss of tungsten to 1%, but the alloy produced was very impure, containing too much manganese, silicon, and carbon. Some of this alloy was refined by smelting in the electric furnace with hematite iron ore, lime, and fluorspar, but the refined metal was still too impure for use. As the ores of tungsten are liable to contain impurities which become reduced together with the iron and tungsten in the electric furnace, thus rendering the alloy impure, it was thought that more satisfactory results would be obtained by the use of pure tungstic oxide instead of wolfram ore. A number of experiments have been made with pure tungstic oxide, and so far the results obtained confirm this opinion. The pure tungstic oxide was made by fusing the wolfram ore with sodium carbonate, extracting the sodium tungstate with water, filtering, and decomposing the sodium tungstate with hydrochloric acid. The tungstic oxide thus produced was washed till free from salt, and dried. A small charge of the tungstic oxide was then mixed with carbon and iron, and the mixture reduced in the electric furnace. The alloy produced was very pure, much purer than that made by the direct reduction of wolfram ore, but it is more expensive to produce, owing to the cost of preparing the pure tungstic oxide.

The Committee has made some inquiries on the production of aluminium in Australia, but has been unable to obtain any information as to the amounts of aluminium or aluminium ware imported into Australia. The best methods of utilising alunite for the extraction of potash and alumina have formed the subject of the investigations of a Special Committee (see p. 078).

The Committee has made inquiries as to the probability of finding rock phosphates and mineral oils in Australia, and also in connection with the utilisation of materials of which large deposits are known to occur in Australia, but which have not hitherto been fully utilised. Under this heading information has been collected in connection with brown

coal, iron and aluminium phosphates, alunite, and clays. The scientific problems connected with the utilisation of these minerals are mainly chemical, and the work on alunite and phosphates is dealt with later. Clays are dealt with in connection with the pottery industry. The Victorian New Industries Committee and the State Government are taking active steps to promote the utilisation of brown coal.

Chemical industry.

A Special Committee has been appointed to investigate and report on the possibilities of local manufacture of chemicals now imported.

The Committee confined its enquiries in the first instance to the possibility of producing locally the so-called heavy chemicals. In order to produce alkalis at a price comparable to pre-war European prices, works would have to be established on a very large scale, and the output of such works would be equal to the amount consumed in Australia. It is obvious that if more than one company undertakes the manufacture of alkali here the chances of making the enterprise a success are considerably reduced, owing to the very limited market in Australia. This applies not only to the alkali industry but to many other chemical industries. The Committee has been informed that a large chemical company is seriously considering the establishment of an alkali works in Australia.

Fertilisers.—Australia is largely dependent on outside sources for the raw material of artificial fertilisers, and the Executive Committee have devoted much attention to the consideration of possible local sources of phosphates, potash, and nitrogenous fertilisers with a view to reducing this dependence of our agriculture on foreign countries. Of most pressing importance is the need for developing local sources of potash. The sources of potash which have been suggested are—(a) alunite; (b) kelp; (c) suint; (d) molasses; (e) wood-ashes; (f) ground igneous rocks; (g) saline deposits.

There is a very large deposit of alunite at Bullahdelah, in New South Wales, and smaller though purer deposits in South Australia. A Special Committee was appointed to consider the best means of utilising alunite, of which the Australian deposits are the most extensive in the world, specially with a view to ascertaining the best treatment for the extraction of the potash. It was found that a comparatively simple process, *i.e.*, that of heating alunite to bright redness for a short period, is the most satisfactory method of treating the mineral. A furnace of the reverberatory type is required. The calcined material contains nearly 30% of potassium sulphate and about 60% of alumina, and may be employed as a potash fertiliser without further treatment. In this case, however, no use would be made of the alumina. By treatment of the calcined material with hot water, the potassium sulphate is separated from the alumina. No serious technical difficulties stand in the way of producing potassium sulphate and alumina from Australian alunite, and the Committee is of opinion that the manufacture of potassium sulphate could be carried on with profit if done on a sufficiently large scale by means of modern appliances, always provided that a local market for the output of the plant could be obtained.

A small plant for treating kelp has been established in Tasmania, and is producing potassium chloride. If the whole Australian wool clip were scoured in Australia and the potash extracted, this would probably suffice for local needs. The recovery of potash in wool-scouring is considered in connection with the production of lanoline (see below). The recovery of potash from molasses

has been considered by a sub-committee of the Queensland State Committee. They had before them details of a method for absorbing the molasses in megass, producing charcoal and gas therefrom, and then burning the charcoal to an ash from which the potash could be recovered. They reported that all methods hitherto tried for recovery of potash from molasses have led to only small proportions being finally recovered, and that the prospect of burning to ash with megass did not appear at all promising, even in war-time. The extraction of potash from the wood ashes of saw-mills and of eucalyptus distillation plant has been suggested, but the amount of potash is probably too small to render this a commercially profitable source. Experiments are being conducted as to the feasibility of extracting the potash from the ash left when prickly pear is burnt. The utilisation of ground igneous rocks as potash fertilisers has often been discussed. The Committee considers that leucite-bearing rocks are unlikely to be able to compete with alunite as a source of potash.

The most satisfactory solution of the potash difficulty would be the discovery of a saline deposit in Australia rich in potash salts. It seems not improbable that such a deposit might exist in some of the lake-basins of Central Australia.

The possibility of increasing the local supply of phosphate fertilisers depends on either (a) the discovery locally of rock phosphates suitable for the manufacture of superphosphates, or (b) the discovery of means whereby the phosphates of iron and aluminium, of which there are considerable deposits in Australia, can be made available as sources of phosphorus to crops. The known deposits of calcium phosphate on the mainland are small. Experiments as to the fertiliser value of iron and aluminium phosphates under different conditions are in progress in Victoria and Western Australia.

The question of the production of nitrates from atmospheric nitrogen has also been considered, and it seems possible that ultimately the Tasmanian hydro-electric scheme may be utilised for this purpose. The Committee have come to the conclusion that, as there is no immediate prospect of Australia being cut off from the supply of Chili saltpetre, the matter should be left until the conclusion of the war.

Other chemicals.—The production of a number of other chemicals in Australia has been considered by the Executive and the Chemical Committee. Amongst these may be mentioned lanoline, cream of tartar, copper sulphate, casein, pepsin, rennet, and other by-products of the meat industry, starch, glucose, and industrial alcohol. The latter is dealt with in connection with alcohol engines in the section on Engineering (see page 1080).

In Australia there is as yet no recovery of lanoline and the other valuable by-products of wool scouring. Hitherto only a very small proportion of the wool exported from Australia has been scoured before shipment, but it is thought that in the future a much greater proportion will be treated here. The Committee has, therefore, taken steps to bring together possible users and producers of lanoline.

During the year 1914-15 the value of the cream of tartar and tartaric acid imported into Australia was over a quarter million sterling. Only a very small proportion of the crude cream of tartar is recovered in the wine-producing States of Australia. The estimated production of cream of tartar in Australia, if recovered, would not equal the amount imported, but co-ordinating committees have been appointed in each of the wine-producing States for the purpose of investigating the matter.

Copper sulphate is now being produced on a considerable scale in Australia, and extensive

establishments for the manufacture of electrolytic zinc and calcium carbide respectively are under construction in Tasmania. The production of white lead in Australia is not equal to the demand, but a factory capable of producing 5000 tons of white lead per annum will be in operation before the end of this year.

The question of the production of casein was investigated, and the evidence obtained showed that the small local demand was already met. In normal conditions the largest gross return is obtained from milk by using it for the manufacture of cheese, the smallest by producing butter and casein. Under these circumstances the manufacture of casein, beyond that required to satisfy local demands, is not likely to be undertaken permanently in Australia, though under present war conditions it would probably be more profitable than cheese-making.

At least one firm has undertaken the manufacture of rennet on a commercial scale, and a factory for the production of starch and glucose from maize has recently been established in Victoria.

Other secondary industries.

Leather and tanning.—The leather industry is one of the most important secondary industries in Australia, yet it seems probable that it will become even more important when tanning is placed on a more scientific basis. The Executive has appointed a Special Committee to investigate processes of extraction of tannin from wattle-bark with a view to the determination of a standard and scientific method of procedure under practical conditions (see also p. 1076).

Food supply.—A Special Committee appointed to examine problems connected with the sterilisation of milk, found that certain thermophilic spore-bearing organisms not only survived, but multiplied at a temperature of 50°–55° C. The changes they produced in the milk were slight and progressed slowly, but the presence of a number of organisms was revealed on culture. In another experiment an alternating current was passed through agar jelly seeded with coliform organisms; no evidence of sterilisation due to electrolysis was apparent, the growth of the organisms being apparently as abundant in the immediate proximity of the electrodes as at a distance from them.

Another Special Committee has studied the growth in a malt wort of yeast leading to rapid ripening of dough. The doughs have been prepared with 270 lb. flour, including the weight of flour used on the table, and 160 lb. water. The average yield of bread has been 175 loaves, weighing, approximately, 355 lb. The doughs have usually stood six hours in the trough, at a temperature of 83° F. For some time doughs standing five hours in the trough were used. The quantity of yeast has been determined by counting the number of yeast cells in a given amount of wort. The weight of yeast obtained from a wort containing a given number of yeast cells has been ascertained. The weight of yeast used in the doughs has varied from 2½ to 5 oz. The acidity of the worts has been usually less than 10 c.c. N/10 acid in 100 c.c. wort, when estimated by titration with methyl orange as indicator. In the preparation of yeast it has been found that the temperature of the wort during the growth of the yeast should be less than the temperature at which the dough stands. Abundant oxygenation favours the development of yeast fermenting rapidly. The presence of flour in the wort prevents any check to fermentation when the yeast is mixed in the dough. The worts have contained about 15% solid matter, of which one half consists of reducing sugars. In the bake-house, the wort is made with a decoction of hops, to which flour and

ground malt are added. This mixture stands at 155° F., until the whole of the starch disappears. The mash is strained from the liquor. The wort is boiled and cooled rapidly. It is placed in a large flat enamel pan, which has been sterilised by boiling water in it for some time. The wort is beaten with a whisk to aerate the liquid, and is inoculated by the addition of a considerable amount of stock from the previous brew. The yeast grows for 16 hours. The multiplication of yeast cells in this time is about ten times, but varies greatly.

Pottery.—Australia possesses an abundance of clay and kaolin suitable for the manufacture of bricks, tiles, stoneware, and various grades of porcelain ware, but deposits of "ball" clay—the white burning, highly plastic clay—are rare. A certain proportion of "ball" clay is required in porcelain work, and it has been found necessary to import this from England. In the manufacture of certain grades of stoneware Australian potteries are not behind other countries, and stoneware pipes have been exported in large quantities to eastern countries, notably the Philippines. In regard to the better grades of clay products the industries are in a very backward state, due chiefly to the need of trained technologists. The Committee is strongly of opinion that active measures should be taken to collect and co-ordinate the data on clays published by the various State Geological Departments, to encourage the establishment of schools of pottery, to assist competent research chemists and physicists in carrying on ceramic investigations, and to induce manufacturers to produce the higher grades of porcelain ware, including domestic porcelain.

The Executive are also endeavouring to arrange for investigations on enamels, glazes, and pottery colours.

Paper-making.—Australia is at present almost entirely dependent on the outside world for its supplies of paper-making materials. The question of the local production of wood-pulp has been discussed above, but, in addition, the Committee have considered the possibility of utilising wheat-straw, marram-grass, and lalang or blady-grass. Preliminary tests of a number of materials have given promising results, but the main difficulty would probably be to obtain a sufficient supply of any except wheat-straw, to enable them to be successfully utilised on a commercial scale. Weeds such as prickly-pear, St. John's-wort, bracken-fern, and lantana, of which large quantities are available, do not appear very promising as sources of paper-pulp. Blady-grass and various weeds are being utilised for paper-making by a company which has recently started operations at Cairns, Queensland.

Textiles. Steps have been taken by the Executive to assist the growing of cotton and flax. A fibrous material of which a large supply is available locally, but for which the best treatment and usages do not appear to have been yet discovered, is the marine-fibre derived from *Posidonia australis*. The fibre has almost no elasticity, so that material made from it will not stretch, and it is unique amongst vegetable fibres in the readiness with which it can be dyed. Owing to its non-conducting and dyeing properties, it is suitable for mixing with wools for the production of low-grade materials. It is also extremely resistant to rot, and not affected by damp or heat. This property may lead to its utilisation in place of jute for bags. As a source of cellulose in the manufacture of cordite, *posidonia* fibre is unlikely ever to compete with cotton, at any rate for military purposes. As a material for paper-making, *posidonia* is fairly promising, but it seems unlikely that it will be able to compete with other materials for this purpose, as it could not be raised, washed, and delivered at a cheap enough rate. Boiling the fibre with caustic soda produces little effect upon it, but it responds readily to

treatment with chlorine, and this might be effected while it is still damp with sea-water, by submitting it to electrolysis.

Engineering. The question of manufacturing compressed gas cylinders in Australia is under consideration, and a Committee has been appointed to examine the design and manufacture of internal combustion engines using alcohol as fuel.

The Committee is of the opinion that the supply of alcohol is likely to prove a much more difficult problem than the question of the design of the engines for its use. The most economical source at the present time for the production of alcohol is sugar molasses; but even if the whole available supply of molasses in Australia were used for the purpose in view, it would be sufficient for the production of only about four million gallons of alcohol per annum, whereas the annual importations of petrol are in the neighbourhood of 17 million gallons. The total average annual quantity of molasses available in Australia for distillation is about 50,000 tons, of which about 12,500 tons is now used for that purpose. The remaining 37,500 tons is largely wasted. The present price of alcohol produced from molasses is about 1s. 9d. per gallon ex-store in Melbourne.

It appears unlikely that any considerable quantity of alcohol can be manufactured in Australia from either raw or waste materials not at present utilised. The most important of these materials are waste timber, grass-tree, prickly pear, waste fruit, and straw. The production of alcohol from cellulose, such as waste timber or straw, is costly, and the prospects of producing alcohol from these sources on a profitable basis do not appear encouraging. The whole question is, however, receiving consideration.

If the required supply of alcohol cannot be produced from raw or waste materials not at present utilised, it will be necessary to grow special materials for the purpose. The most promising sources in this respect appear to be maize, wheat, barley, potatoes, and beet. The Committee has obtained information on these matters from various distillers and other persons, and is making further enquiries.

The following figures have been collected from various sources, and represent the approximate yield of alcohol under practical conditions from various substances:—

Material.	Imperial gallons of alcohol (95%) per ton (2240 lb.).
Maize	80—83
Barley	65—70
Wheat	80—85
Potatoes	16—24
Beet	12—16
Apples and pears	9—14
Apricots and peaches	9—13
Grass-tree	12
Sawdust (soft woods)	20
Grapes	18
Molasses	65—70

It has been proposed that alcohol should be used as a fuel in admixture with other materials, such as benzene, ether, or acetylene. The Committee consider, however, that it is desirable to aim primarily at the adoption of stationary engines using alcohol alone, in view of the higher thermodynamic efficiency of that substance as a fuel. Concurrently with the development of such an engine, the Committee propose to take steps with a view to bringing alcohol, either as an admixture or alone, into general use for motor-

car work. The Committee are, accordingly, making enquiries with a view to the production in Australia of suitable materials to be used as an admixture with alcohol, and as to the efficiency of the various admixtures.

The denaturants at present necessary for industrial methylated spirits, under the Excise Act and Regulations, are as follows, viz.:—2% of wood naphtha, $\frac{1}{2}$ % each of pyridine and mineral benzene. The cost of these denaturants is 1.74 pence per gallon of alcohol. In order that power alcohol may be available at as low a price as practicable, it is desirable that an alteration should be made in the existing regulations as to denaturation. The Committee are in communication with the Comptroller-General of the Department of Trade and Customs on the matter, and have asked if the addition of 1% of pyridine only would be satisfactory. This would reduce the cost of denaturants to 0.9 penny per gallon of alcohol. The suggestion was not acceptable to the Customs authorities, who have, however, granted permission for the Committee to obtain a supply of a quarter-cask (32½ gallons) of spirit for experimental purposes denatured in the manner suggested.

The Committee are making enquiries, and are collecting data with a view of determining upon a cheap and efficient denaturant which can be produced in Australia. In this matter, particularly it is proposed to co-operate with the Imperial Motor Transport Council, London, with a view to obtaining a denaturant which will be generally acceptable throughout the Empire.

Standardisation.

General.—The Committee consider that it is of importance that arrangements be made for the following standardising work to be carried out, viz.:—(a) The standardisation of scientific apparatus and instruments. (b) The testing of electric lamps, apparatus, and machinery. (c) The testing of instruments of precision used in industry. (d) The physical testing and standardisation of materials used in industry and by the Commonwealth Government.

A beginning in this direction has been made in respect of standardisation of analytical methods in the chemical industries, and the appraisalment of alcohol in spirituous liquors. During the past two years the Society of Chemical Industry of Victoria has, in co-operation with various scientific, industrial, and commercial interests, formulated the details of a scheme for a series of investigations with a view to determining standardised methods of analysis for use in the chemical industries. The scope of the work planned may be summarised as follows, viz.:—(a) To review the best methods of analysis of materials. (b) To compare the standard methods of other countries. (c) To study the results of investigations made with those methods by various workers. (d) To conduct comparative tests on proposed methods. (e) To recommend methods for general adoption. (f) To keep in touch with all current work on analytical methods, and to report on new methods, and on old methods in the light of new research. The work is to be carried out gratuitously by members of the society.

The appraisalment of alcohol in spirituous liquors.—Under the existing system alcoholic liquors are valued in terms of "Proof spirit" (spirit of specific gravity 0.9198 at 60° F.). Proposals have been made that such liquors should be valued in terms of percentage of alcohol, and a memorandum has been forwarded to the Reconstruction Committee with a suggestion that it should be referred to Lord Balfour of Burleigh's Committee on Trade Policy after the War.

NITROGEN FIXATION.

In connection with the efforts that are being made in the United States to secure an adequate supply of nitric acid and nitrates, Dr. C. L. Parsons, as a result of enquiries and visits to plants in Italy, France, England, Norway, and Sweden, has prepared a report on the different processes in use. His conclusions are based on an estimate of the U.S. Government's maximum requirements of nitric acid for munitions purposes, viz., 20,000 tons in peace time and 180,000 tons in time of war. Dr. Parsons says: With these quantities as a maximum, and a sufficient supply of sodium nitrate in storage to meet the requirements of the Government for a period of six months to one year, no serious emergency problem confronts the Government. The increase in the output of ammonia from by-product co-ing since 1915, if oxidised to nitric acid, is alone more than sufficient to meet this requirement. The oxidation of ammonia, including that produced from the destructive distillation of coal, presents no serious difficulties, and the necessary plants using the emergency procedure adopted in Germany could in case of need be quickly installed to meet the Government requirements. Such installation would involve much cruder procedure, such as lower efficiency of oxidation and absorption of the nitrous oxides in soda lye, than would be adopted after careful experimentation and experience in the operation of the most efficient plants, but it would nevertheless furnish the country with the nitric acid required.

In my opinion, the following methods include the only ones which need to be considered in the final choice of the procedure to be employed by the Government in providing a source of nitrate supply.

Arc process.

The arc process is now installed in Southern Norway, employing 250,000 kilowatts of electricity developed from the cheapest large installation of hydro-electric power in the world. This is the only large installation of the arc process, but small installations of an experimental nature have been made in other countries. The method is one of the most inefficient known as regards production in relation to power consumed. Nevertheless, on account of the very cheap horse-power available in Norway, nitric acid can there be produced by the arc process at a cost less than by any other commercial process. Incidental to the production of nitric acid, a large excess of heat is developed, which can be, and is in part, converted into steam, which may be, and is, used for concentrating the weak nitric acid obtained in the absorption towers to the strong acid required for munitions works. The excess of steam is so large that many other methods for its application have also been devised. As the labour costs also are low, when once under way the operation goes on almost automatically. As the formation of nitric acid is direct and involves only the nitrogen and oxygen of the air and water as raw materials, no complicated processes involving intermediate products are necessary, as is more or less the case with all other processes.

In spite of these manifest advantages, however, it appears to be the general opinion of the European engineers with whom I came in contact that even with the cheap horse-power enjoyed by the Norwegian plants, they might have had to discontinue their operations except for the stimulus given by the present European war. Even as it is, the Norsk Hydro Company, operating the arc plants at Notodden and Rjukan, have been obliged to install large ammonia-producing plants in order that they might convert their nitric acid

to ammonium nitrate and thus render it transportable to markets where it was needed.

The cost of horse-power used for the production of nitric acid in Norway is less than \$5 per horse-power year. With horse-power at \$10 per horse-power year, the cost of finished strong nitric acid at the plant should be as cheap as by any other process now in operation. However, the low cost of producing nitric acid by the arc process is outweighed by so many other disadvantages that, in my opinion, the process is entirely inapplicable to the use of the United States Government, and this opinion appears to be shared by all who have given careful thought to the subject. The cost of installing the arc process is high, and it involves the use of an amount of horse-power that seemingly is not available on the American continent within reach of the points where the nitric acid would have to be used.

The great difficulty that has faced the Norwegian plants from the beginning, namely, a market for their products, would in peace times be a serious obstacle to the operation of a large arc plant in the United States. An arc plant at its best involves the use of 2-33 horse-power years per ton of weak nitric acid. This means that a water-power development of at least 50,000 horse-power would be necessary for the peace requirements of the Government, and a development of 440,000 horse-power would be required for war purposes. These figures are minimum figures on the basis of the relatively high efficiency reached in Norway. No installation should be considered by the Government of less than 75,000 horse-power for peace requirements or 550,000 horse-power for war requirements. If the arc process is to be used it would also be advisable to arrange for the production of explosives at the point where the arc plant was located. This would, of course, involve the transportation of all other raw materials needed to the plant and transportation of the finished explosives therefrom to the place of consumption. As these materials are highly combustible and for the most part carry high freight rates, it has been found necessary the world over to locate the plants intended for the production of munitions near to the point where the munitions are likely to be consumed.

An arc plant of sufficient size to meet the requirements of the Government in time of war would probably have to remain idle for the main part during times of peace, owing to the difficulty of disposing of the nitric acid that the plant would produce if in operation. On account of the large amount of horse-power required and the consequent extent of the necessary plant and tower absorption capacity, the cost of installing an arc plant to meet the war time requirements of the Government would be several times the total appropriation made for the purpose by Congress.

Haber process.

The Haber process has grown very rapidly in the last three years. It was first commercially installed in Germany in 1913 with a plant capacity of 30,000 tons of ammonium sulphate. Seemingly, it actually produced in that year some 20,000 tons of ammonium sulphate. This grew to 60,000 tons in 1914; 150,000 tons in 1915; and 300,000 tons in 1916; and it is authoritatively stated that with new works now under construction by the Badische Company, the 1917 output of ammonia by the Haber process would be equivalent to over 500,000 tons of ammonium sulphate.

The production and purification of hydrogen made either by the reducing action of coal or iron upon steam involve one of the chief items of cost in the Haber process. The fact that the

combination of nitrogen and hydrogen takes place at temperatures above 500° C., and at pressures of 125 to 150 atmospheres, involves some danger and many other technical difficulties which have, however, seemingly been overcome in Germany. The technical control of the Haber process is of such great importance and requires so high a degree of training and skill that it is reported if the Badische people were to lose their present technical staff of experts, familiar with the process, many months would be required to train another staff capable of applying the process in practice.

The Haber process is not at present in use outside of Germany on account of the lack of detailed information regarding plant construction and operation, and also owing to the very large royalty demanded by the Badische Company for its use by other concerns. It is, however, more than probable that the Badische Company will itself install and develop the process outside Germany when the war is ended.

Trustworthy information regarding the costs of production of ammonia by the Haber process indicates that pure anhydrous ammonia can be produced in liquid condition at a cost slightly less than 4 cents per pound. It is improbable that any arrangement could be made for the United States Government to use the Haber process pending the conclusion of the European war. It is probable that when the war is ended, the Haber process will be installed or will be available for installation in the United States. It is the cheapest process for the production of synthetic ammonia. It is independent of cheap power—the power being a small fraction of its cost. If desirable, it could be readily installed in moderate-sized units in connection with ammonia oxidising plants at any munitions plant.

Cyanamide process.

The cyanamide process has been developed in many parts of Europe, but in the Western Hemisphere only at Niagara Falls, Ontario, Canada. It requires cheap power for its successful operation and has obtained its greatest development owing to the fact that it requires only about one-fifth the horse-power per ton of fixed nitrogen per year that is required by the Haber process.

Ammonia from cyanamide, with power at 88 per horse-power year in a plant to be constructed by the Government, would cost 1 to 2 cents per pound more than by the Haber process. On the other hand, royalties for using the cyanamide process would undoubtedly be less. The technical problems involved are understood by many engineers both in this country and abroad, the manufacture of calcium carbide and cyanamide being established in many plants, and the basic patents having only some four years more to run. Peculiarly favourable conditions exist for its installation in certain sections of the South. If a hydro-electric plant is to be installed by the United States Government, and the electrical power so developed be used for the fixation of nitrogen, the cyanamide process has advantages over all other processes now developed, and should be adopted as the best means of utilising hydro-electric power for the fixation of nitrogen.

In Germany in 1913 there were produced 30,000 tons of cyanamide. The growth has not been so rapid as in the case of the Haber process, although the process has been subsidised by the German Government to assist in its development. However, the 1917 German production will be not far from 400,000 tons. The cyanamide interests in Germany have also endeavoured to induce the German Government to establish a nitrogen monopoly which will ensure the continu-

ation of the cyanamide industry in Germany in competition with the Haber process and ammonium sulphate from coke ovens after the war. Cyanamide has not found favour with American fertiliser manufacturers, and is not well suited as an addition to the mixed fertiliser demanded by American farmers. It is, however, successfully used in Europe where labour is much cheaper. To meet the Government's requirements of 20,000 tons and 180,000 tons of nitric acid through the medium of cyanamide would require the continuous use of 11,000 horse-power and 99,000 horse-power respectively.

If cyanamide is to be converted into the most popular form of fertiliser material, namely, ammonium sulphate, it would cost approximately 1 cent per pound to convert the nitrogen present into the form of ammonia before it could be absorbed to form sulphate. It is the necessity of converting the combined nitrogen into ammonia, if the cyanamide process is used as a source of nitric acid, that makes up a considerable portion of the difference in cost between cyanamide ammonia and Haber ammonia.

By-product ammonia.

In the United States less than one-tenth of the bituminous coal burned is coked in by-product ovens. Of the coke produced in America, over one half is still produced in beehive ovens in which the gas, ammonia, and all other by-products are ruthlessly destroyed. There has been nevertheless a rapid increase in the installation and operation of by-product ovens, and an increase in ammonia production that would not have been thought possible two years ago. By the end of the present year we will be producing at least 115,000 tons of ammonia per annum—an equivalent of 450,000 tons of ammonium sulphate. Six thousand tons of this ammonia in time of peace, or 55,000 tons in time of war, would meet the nation's requirements of nitric acid for military purposes, as estimated by the War Department. The growth of our ammonia production from by-product coking has been extremely rapid, and is still on the increase. More than fifty million dollars' worth of by-product coke ovens have been contracted for within the past twelve or thirteen months, and are now completed or in process of erection.

The general use of coke instead of coal throughout the United States would produce, besides other by-products, approximately 1,000,000 tons of ammonia. The day is far off before this highly desirable result will be reached, but it should none the less be striven for. Already legislation abroad requires the use of coke instead of bituminous coal for certain industrial purposes. By-product coke ovens, however, cannot be installed by the United States Government for the purpose of producing ammonia. The ammonia should be simply a by-product incidental to the production of coke for industrial purposes. Under war conditions, however, the output of ammonia from by-product coke ovens could, by Government regulation, be greatly increased. This has been accomplished in Germany, the by-product coke ovens furnishing Germany to-day with over one-third of the nitrogen consumed in that country. Germany has had an increase from 100,000 tons to 154,000 tons of nitrogen from this source since the war began. The possibilities for an increase in America are much greater than in Germany.

Ammonia from by-product ovens has to be purified before it can be oxidised to nitric acid. The cost of purification is, however, very small, and where purification apparatus is installed at the original ammonia absorption plant, adds but a small fraction of a cent a pound to the cost of crude ammonia liquer.

The use of by-product ammonia for the production of nitric acid for munitions purposes has the great advantage that it is already available, and that the plants, being situated in numerous parts of the country, could furnish ammonia to several small oxidising plants. Accordingly, the country's source of munitions supply would not be at any one place, and subject to capture and destruction.

The use of by-product ammonia has the great disadvantage that the present selling price of ammonia from by-product coke is high, and unless considerable price concessions could be obtained by the Government, it could not afford to utilise this source of raw material for nitric acid. The actual cost of pure ammonia, considered as a by-product from the coking of bituminous coal, is much less than by any other method now producing this substance.

Cyanide process.

The cyanide process is not yet a commercial success, but it has great possibilities. There is no difficulty whatever in the chemical reactions. No power factor of any consequence is involved, and it appears certain that if the mechanical difficulties are solved, nitrogen will be fixed in this form cheaper than by any other known synthetic process. There are also large quantities of waste nitrogen available in connection with the sodium carbonate plants of the country, where the sodium carbonate required would also be available, and there are large amounts of nitrogen that could be obtained without cost in a sufficiently pure condition at the wood-pulp plants using the sulphite process.

When the sodium cyanide is once formed it can be readily converted into ammonia, as is the case with cyanamide, but the process has the advantage that in the conversion the sodium carbonate can be recovered to be used over again. The iron can also be repeatedly used in the process. Small installations are now working successfully in the country, but the mechanical difficulties of production on a large scale are yet to be solved. Four large American corporations are engaged on the problem with ample funds for its solution.

The process has the further advantage that it would also make cheaply available cyanide which is so greatly needed by our mining industries.

Nitric acid from ammonia.

All processes for the synthetic production of nitric acid, except the arc process, involve the oxidation of ammonia. The processes commercially in use involve the direct oxidation of ammonia gas in the presence of air in contact with metallic platinum. In Germany, according to the latest published figures, approximately 100,000 tons of nitric acid are annually produced through the Frank-Caro process, which involves passing mixtures of ammonia and air through electrically heated platinum nets of 80 to 100 mesh. The platinum is heated to a dull red heat, and serves as a catalytic agent under whose influence the ammonia, instead of burning to nitrogen and water, as normally would be the case, is oxidised to nitric oxide.

In the Kaiser process, also used in Germany, the air is heated before its mixture with the ammonia, and under these conditions it is claimed that no electric heating of the platinum net is necessary. The Kaiser process does not appear to have reached any large commercial development.

In the Landis process, installed in a small experimental plant at Warners, N.J., the gas is passed downwards through the net instead of upwards, as is customary in the Frank-Caro process, and, according to the Landis patents, the gases are cooled before they are allowed to come in contact with

the net instead of being heated as in the Kaiser process. The platinum-net process is also understood to be installed in a small plant in Long Island City, and is being installed in Syracuse, N.Y., by the Semet-Solvay Company in co-operation with the Bureau of Mines.

The Ostwald-Barton process, first developed at Villevalde, Belgium, and brought there to a commercial success at the time of the opening of the war, is now installed in two large plants—one at Angoulême, France, and the other at Dagenham, England. The principle of the process is essentially that originally patented by Ostwald, but the catalyser is distinctly different from that used by him, although it consists of metallic platinum. The details of the preparation of this catalyser are kept secret, but it is known to have a very small cross-section, and is placed at the end of a 60-mm. tube, so that the products of combustion passing through the tube heat the mixed ammonia and air by radiation as they approach the catalyser. By this means no external heat is necessary. The reaction when once started continues without interruption for weeks. It is simply necessary, by means of blowers, to force the mixture of ammonia and air through the catalyser. The present commercial efficiency and output by the Ostwald-Barton process is higher than by any other concerning which exact figures have been obtained. It is higher than the published figures for the Frank-Caro process, but as figures for that process have been published only on a minimum basis, it is impossible to state whether as high an efficiency of conversion and capacity of catalyser has been reached by that process as by the Ostwald-Barton.

The processes for the oxidation of ammonia are seemingly free from any complicated patent situation. The Europeans engaged in ammonia oxidation admit freely that they have no important patent rights to sell, but they claim that they have plans, specifications, and details of processes, the purchase of which would be cheaper than the necessary experimentation to work out the details.

By the oxidation of ammonia, nitric oxide gases are obtained of much higher concentration than those produced by the arc process. Accordingly, much less tower space is necessary for their absorption, and much stronger acid can be directly obtained by concentration. Although in the arc process the concentration of 30 to 35% nitric acid to strong acid is required, in the oxidation process an acid of 50 to 55% strength is easily obtained directly from the towers, and the concentration thereof is accordingly a simpler matter.

A method has been developed in Sweden, details of which are unknown, for the oxidation of ammonia or cyanamide direct to ammonium nitrate in solution. Plants have been erected near Gothenburg, Sweden, and near Berlin, Germany. It is claimed that this process will produce ammonium nitrate much cheaper than any other.

The nitrogen situation.

In view of the fact that Germany has invested millions of dollars in synthetic nitrogen plants which will continue to produce nitrogen compounds after the war; that Germany is producing more than twice the amount of combined nitrogen that she formerly imported in the form of Chilean saltpetre; that accordingly the German market for Chilean saltpetre will be essentially non-existent after the war; that the present large American and allied consumption for munitions will cease; and that during the war the American production of ammonia from by-product coke ovens has increased to a point in excess of our apparent normal consumption, it seems certain that the

price of combined nitrogen for industrial and agricultural purposes must greatly decrease when the war is over.

It is evident at once that the peace-time requirements of the Government for nitric acid could be supplied from coal-tar ammonia with little effect on the market for the material and practically no effect on the country's nitrogen resources. It seems equally certain that in the case of war by-product ammonia could furnish 180,000 tons of nitric acid per year for at least one or two years without seriously affecting the nation's agriculture. This is particularly important when it is remembered that over 60% of the nitrogenous material used in fertiliser, consisting of organic nitrogen from cottonseed meal, tankage, dried blood, etc., would not be decreased at all, but would rather be increased through the cutting off of exports of cottonseed meal.

Furthermore, it is well known that several of our largest corporations are engaged in active plans for installing synthetic nitrogen plants of various kinds to meet their own industrial requirements, and that in all probability the Haber process will enter into active industrial competition for our ammonia markets in American plants as soon as the war is over. Plants for the oxidation of ammonia can be quickly erected in crude form, as they were erected and utilised in Germany, should the need arise.

I accordingly feel that no serious emergency problem confronts the United States that could not be met with reasonable celerity in time of war, and that our first problem, after securing a reasonable reserve of Chilean saltpetre, is to familiarise ourselves with the most efficient method for the oxidation of ammonia and to train the necessary men to construct and operate ammonia oxidation plants.

Cost of nitric acid.

The cost of nitric acid, *per se*, whether as weak nitric acid or as concentrated nitric acid, is lowest by the arc process with hydro-electric power delivered to the furnace at a cost of \$10 per horse-power year, or less. The difficulties of its transportation, the large amount of power required, and other economic reasons, as already explained, make the arc process inapplicable to American conditions.

The cost of nitric acid obtained by the oxidation of pure ammonia is independent of the source of the ammonia, and must therefore depend upon the cost of ammonia gas in the gasholders ready to be passed to the oxidising apparatus.

Cost of ammonia.

The cost of ammonia has at the present time no relation to its selling price. The actual cost of collecting, absorbing, and purifying ammonia from the gases developed by the destructive distillation of bituminous coal, in other words, the cost of ammonia considered as a by-product, is less than by any other process. The selling price of by-product ammonia is entirely a question of competition with other nitrogenous products, and has been fixed in the past almost wholly by the market price of sodium nitrate, with which it enters into competition. Even should ammonia be placed on the market by the Haber process at a price as low as 4 cents per pound, by-product ammonia will still be sold in competition therewith at a profit to the producer. The Haber process can produce, and is producing, ammonia synthetically cheaper than any other synthetic process now industrially applied. The cyanamide process stands next in order.

If mechanical difficulties now confronting the cyanide process are solved, it will produce ammonia cheaper than either the Haber or the cyanamide

process, and in close competition with the actual costs of saving by-product ammonia. The details of costs by all of the above methods will be considered in the final report.

Summary of conclusions.

(1.) The Government should obtain its nitric acid by the oxidation of ammonia. It should begin the erection of an ammonia-oxidation plant of moderate capacity at an early date in order to train men and obtain experience in the most efficient method of procedure.

(11.) The Government should proceed slowly in the matter of the erection of plants for the production of ammonia, as developments in the cyanide process and the availability of the Haber process may render valueless within a short time any large expenditure for the production of cyanamide. This is doubly true in view of the fact that present appropriations are not nearly sufficient to install water power and erect the nitrogen fixation plants necessary to meet the Government requirements as estimated by the Ordnance Department.

The adoption of the above procedure involves:—

1. Purchase by the Government of a reserve supply of sodium nitrate of at least 200,000 tons.

2. The purchase of ammonia on the open market.

3. The reservation of a supply of platinum.

4. The construction of a hydro-electric plant only if the arc or cyanamide process is to be used. The oxidation of ammonia requires very little power, and the Haber, cyanide, and by-product ammonia processes are all independent of cheap power cost. The development of water power, however, cannot but be of benefit to the country even if it is not used for the fixation of nitrogen.

I seriously doubt whether hydro-electric power will be necessary or desirable three years from now for the most efficient process of fixing nitrogen, and accordingly I deem it unwise to install such hydro-electric power, at great cost, with the sole purpose of fixing nitrogen. If, however, such water power can be utilised by the Government in the production of certain ferro alloys absolutely essential for ordnance and other munitions; can be sold to commercial companies who will take upon themselves the financial risk involved in the erection of plants for nitrogen fixation, under guarantee of cheap ammonia to the Government; or can be sold during peace times to companies requiring power for purposes which would allow instant requisition of the power by the Government in time of war without handicapping the supplies of other needed war material, the development of such hydro-electric power would be highly desirable.

The first and third recommendations have already been adopted, and are progressing towards fulfilment.

In a supplementary report, dated April 30th last, Dr. Parsons states that a small plant for the oxidation of ammonia erected at Syracuse, N.Y., is progressing successfully; another experimental oxidation plant at Laurel Hill, Pa., has developed other new features. At Syracuse two new forms of apparatus for the oxidation of ammonia are now being tried—one of which, if successful, will do away entirely with the use of platinum in the production of nitric acid.

Development has been rapid during the last two months. A synthetic ammonia process and a cyanide process have now reached a state of development where I am prepared to recommend definite action by the Government.

General Chemical Company process.

During the past four years the General Chemical Company, working on the basis that it should be

possible to develop conditions under which the synthetic production of ammonia by the direct combination of nitrogen and hydrogen should take place at lower pressures than those deemed necessary by the Haber patents, has achieved success. This process has been in successful operation on a large experimental scale with several small units for ammonia production, and one unit larger than those supposed to be used in Germany. The General Chemical Company has also developed and brought to a commercial basis the production of a mixture of nitrogen and hydrogen from coke, air, and water which will yield hydrogen at a cost lower than heretofore obtained in this country, and probably lower than that obtained in Germany. Complete engineering plans have been prepared and bids obtained on the main items of construction, so that the erection of a plant for the synthetic production of ammonia can be proceeded with without delay. The company itself would have already had a plant in operation save for the present high construction costs and other difficulties incident to operations at the present time.

The General Chemical Company has offered the free use of their process to the Government, and the full help of the Company in installing and operating the process.

It is estimated—I believe conservatively—that even under present conditions a 30-ton-per-day plant can be built for an expenditure of \$3,000,000, and can be operated at a cost of not to exceed 4 cents per pound of ammonia produced, allowing \$5.00 per ton of product for repairs and 12½% of the cost of the plant for interest and depreciation. It is believed that the charges for repairs, interest, and depreciation are excessive, as, together, they comprise more than 50% of the total cost of the ammonia production. In the estimates \$3.00 per ton of product is allowed for general expenses and overhead charges.

It is estimated that a smaller plant of at least 7½ tons per day capacity can be built at the present time for approximately \$1,100,000, including land and building. Such a plant would yield 2700 tons of ammonia per year—equivalent to 8700 tons of 96% nitric acid, assuming 85% recovery. Such a plant would require about 500 horse-power.

I recommend that an initial plant to produce 60,000 lb. of ammonia per day be immediately constructed, and to this end I recommend that the War Department set aside the sum of \$3,500,000, and that the initial plant be constructed at some point to be selected by the War Department in South-West Virginia, or adjoining territory in West Virginia, reasonably near to the sulphur, sulphuric acid, and coal supplies of that region, and so situated near to plenty of good water that an ammonia oxidation plant and a powder plant may later be erected near by.

Cyanide process.

The cyanide process, too, has greatly developed in the last few months.

The president of the Nitrogen Products Com-

pany considers the process a certain commercial success, and a probable competitor with any other process for the production of fixed nitrogen. The Company is operating two experimental plants by the cyanide process—one at Saltville, Va., in a coal-fired furnace, and one at Niagara Falls in an electric furnace.

After careful examination of this process, I am not convinced that it has yet reached a point where plant installation should begin, as I believe a few months' experimentation will add greatly to the efficiency of the furnace proposed. It is my belief, however, that the process will become an important factor in the world's nitrogen market; that it may become a strong competitor even of other processes on account of the simplicity of its operations and the low cost of plant construction; and that a furnace which I believe I see in embryo can be developed which will be much more efficient than either of those now used.

The process is so promising that I recommend that active experimentation on a large scale be conducted, that a sum not to exceed \$200,000 be set aside for this purpose. With this amount available I feel confident that this process can be put upon a commercial basis; that it will become a real competitor in the production of ammonia for nitric acid and of nitrogenous material for fertiliser.

Estimates of construction and operating costs.

In order that the recommendations made above may be considered in comparison with the older processes now operating on a large scale, I submit herewith a table summarising confidential data obtained from books of many companies bearing upon the cost of nitrogen production.

Data per ton of nitrogen—by the Arc, Cyanamide, Haber and General Chemical Company Processes.

	Arc.	Cyanamide.	Haber.	Gen. Chem.*
Product	35% HNO_2	NH_3	NH_3	NH_3
Power required	10.5	2.2	0.2	0.2
Investment	\$1410(a)	\$440(a)	\$340	\$300
Operating costs†	170	150(b)	119	97
Product	96% HNO_3	96% HNO_3	96% HNO_3	96% HNO_3
Power	10.8	2.3	0.3	0.3
Investment‡	\$1550	\$670	\$570	\$530
Operating costs§	220	270	230	217

* Estimates on General Chemical Co. process are based on present war time construction costs. All others on normal prices.

† Amortisation for cyanamide as charged by operating companies. Amortisation for Haber 20% of plant cost for repairs, interest, depreciation. Amortisation for Arc and Modified Haber 12½% interest and depreciation. \$5.00 per ton of product for repairs.

‡ Except for Arc process, includes ammonia plant as given power additional \$10, oxidation and absorption, \$140; concentration \$40; steam plant \$40.

§ Except for Arc process, includes ammonia costs as given; oxidation \$50; concentration \$70. No allowance made for unoxidised ammonia.

(a) Power plant investment reckoned at \$100 per horse power.

(b) Cyanamide production \$122, ammonia from cyanamide \$28, total \$150.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron 8, Paris (3e.)
Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Furnace; Gaseous fuel.—A. C. Ionides, jun., London. Eng. Pat. 108,701, Aug. 11, 1916. (Appl. No. 11,371 of 1916.)

A MIXTURE of gas and air in nearly theoretical proportions is delivered, by one or more jets, into a combustion chamber, and the hot products of combustion pass upwards into the heating chamber through narrow annular or longitudinal passages. The waste products pass out of the top of the heating chamber and thence down through narrow passages between the wall of the heating chamber and the outer wall of the furnace, to the waste gas flue below.—W. H. C.

Heating water or other liquids; Apparatus for.—Ajax Heaters, Ltd., and R. C. Bussell, London. Eng. Pat. 108,737. (Appl. Nos. 11,969, Aug. 23, 1916, and 811, Jan. 16, 1917.)

A TRUNCATED conical chamber which may be formed of superposed sections, is surrounded by an outer casing. The heating medium is supplied to the interior of the chamber, and is directed towards the walls by baffles. Annular perforated channels are formed at intervals round the outside of the chamber, which may have annular corrugations on the outside. The liquid to be heated is fed into a perforated annular trough at the upper end of the chamber and passes through the perforations on to the wall of the chamber, down which it flows as a film. The annular channels serve to re-distribute the liquid as a film, and the heated liquid collects in the annular space between the bottom of the chamber and the outer casing, and flows away through a superheater situated within the lower part of the conical chamber.—W. H. C.

Exhaust gases from heat engines; Method of and apparatus for the utilisation of the heat of.—W. A. Mitchell, Plymouth. Eng. Pat. 108,744, Aug. 30, 1916. (Appl. No. 12,283 of 1916.)

THE exhaust gases pass first round a steam boiler which projects into the exhaust pipe. The steam produced passes into a chamber filled with iron turnings which surrounds the continuation of the exhaust pipe. The steam is decomposed by the iron, hydrogen and iron oxide being formed, and the hydrogen is conducted to the combustion chamber of the heat engine.—W. H. C.

Refrigeration; Apparatus for mechanical.—A. S. Cachemaille, London. From J. C. Bertsch, Edgewood Park, Pa., U.S.A. Eng. Pat. 108,759, Sept. 13, 1916. (Appl. No. 13,011 of 1916.)

A ROTARY pump compresses a volatile fluid and delivers it into a coil in a cooling chamber, where the liquid evaporates and produces cold, the vapour passing to a coil cooled by water and connected through a separator with the inlet of the compressor. The inlet and outlet ports, the lubricant-distributing chamber, and all pipe connections are within the cylindrical wall of the compressor.—W. H. C.

Ice or refrigerative effects; Apparatus for the production of.—W. R. Ormandy, London, and W. E. Calvert, Halifax. Eng. Pat. 108,894, Aug. 21, 1916. (Appl. No. 11,855 of 1916.)

IN a refrigerating apparatus of the type in which a gaseous refrigerant such as ammonia is absorbed by an absorbent such as ammonium nitrate mixed with kieselguhr (see Eng. Pat. 107,040 of 1916; this J., 1917, 917), means are provided for reducing the quantity of heat supplied to or taken from the surrounding pressure-resisting casing. The casing is lined internally with insulating material to avoid contact with the supports for the trays which carry the absorbent material. The material is cooled or heated by spiral pipe coils in the trays supplied from and discharging into common headers, one at the side and the other in the centre of the casing. The refrigerant is supplied by a pipe at the top of the casing.—W. F. F.

Refrigerating apparatus.—B. E. D. Kilburn, London. From Sulzer Frères Soc. Anon., Winterthur, Switzerland. Eng. Pat. 109,320, Oct. 6, 1916. (Appl. No. 14,228 of 1916.)

THE apparatus consists of a pump, jet, and cooler for compressing and liquefying the refrigerating gas, the working liquid of the jet flowing through the jet and the pump and also in a closed circuit through the cooler. The pump is surrounded by the cooler, and the jet compresses and also liquefies the refrigerating medium.—J. H. P.

Filter-presses.—W. Guerrero, Madrid. Eng. Pat. 108,869, May 1, 1916. (Appl. No. 6215 of 1916.)

FILTER-PLATES for supporting and separating the filter cloths are constructed of intertwined helical coils of wire, forming an openwork grating with an interior free space through which the filtered liquid may be withdrawn. The frame carrying the grating may be supported between two outer frames carrying cross-bars to support the grating. The grating may be held in position in a groove in the frame or in a groove formed by the two outer frames projecting slightly beyond the inner frame. Alternatively the grating may be secured to the frame by straps or screws, or the frame may be cast on to the grating to form a solid body.—W. F. F.

Filters.—E. C. R. Marks, London. From Zahn Manufacturing Co., Buffalo, N.Y., U.S.A. Eng. Pat. 108,897, Aug. 25, 1916. (Appl. No. 12,068 of 1916.)

LIQUID to be filtered enters an inlet chamber of circular cross-section containing porous filtering tubes projecting inwards from one of its flat sides. Each filtering tube is provided with a tubular neck passing through the side of the chamber into a similar outlet chamber placed face to face with the inlet chamber. The adjacent sides of the inlet and outlet chambers are slightly separated and one of them is provided with a projecting circumferential flange seating upon the other, with an intermediate packing ring, thus forming an intermediate chamber for leakage from the inlet chamber. The intermediate chamber contains a network of stiffening ribs and a number of spacing bosses.—W. F. F.

Drying apparatus for use in drying fruit, vegetables, herbs, chemicals, powders, seeds, minerals, fibre, and the like. F. Hewett, London, Eng. Pat. 108,915, Sept. 8, 1916. (Appl. No. 12,742 of 1916.)

In apparatus for drying fruit, vegetables, and other products, of the type described in Eng. Pat. 106,549 (this J., 1917, 858), tiers of trays are used having front and back rails, A, B, and inner rails, J, F.

supporting gauze, G, for carrying the material to be dried. Hot air enters at D, and passes upwards through the material to the outlet flue, I. In a modification, the rail, J, may be inclined downwards towards the rail, A. In another modification, the rail, B, may be omitted and replaced by the wall of the casing and the trays may be supported on runners. The trays may be reversed so that the air current passes downwards through the material to be dried. The width of the flues, D, I, may be varied, or the trays may be arranged at an angle to the horizontal so as to overlap one another.—W. F. F.

Elevating liquids; Apparatus for automatically — W. A. Coxon, London, Eng. Pat. 108,921, Feb. 14, 1917. (Appl. No. 13,310 of 1916.)

AN upper chamber in the receptacle for the liquid to be elevated contains an oscillating valve for controlling the supply of compressed air and the air exhaust. This valve is operated by means of a slotted hollow float which is actuated by the rise and fall of the liquid in the receptacle. When the liquid in the receptacle reaches a certain level, the oscillating valve closes the air exhaust and admits compressed air, which expels the liquid through a rising delivery main fitted with a non-return valve. The rising main is connected with the liquid-supply pipe, and the back pressure set up by displacement of the liquid lifts and closes a valve on the liquid-supply pipe. When the liquid in the receptacle falls to a certain level, the oscillating valve shuts off the supply of compressed air and opens the air exhaust, whereupon the valve on the liquid-supply pipe drops by the action of gravity and admits a further supply of liquid to the receptacle.—J. H. P.

Moistening, humidifying, and otherwise treating air and the like with liquids; Apparatus for — G. F. Jackson, Blackburn, Eng. Pat. 109,913, Mar. 21, 1917. (Appl. No. 4099 of 1917.)

Air is forced through a spraying device mounted inside a main conduit and is discharged through lateral ducts. Any condensed moisture is caught by sleeves which extend slightly beyond the outer orifices of the ducts. The moisture is carried back by a main channel to the space within which the spraying device is situated.—J. H. P.

Mixing machines or the like. J. Miller, and G. Fletcher and Co., Ltd., Derby, Eng. Pat. 109,038, June 28, 1917. (Appl. No. 9278 of 1917.) Addition to Eng. Pat. 102,034, Aug. 5, 1916.

In a mixing machine in which a pair of archimedean spiral mixing blades rotate in adjacent troughs, the troughs meet at an edge, 8, which forms part of a detachable blade, 7. To lock the

blade without any projecting bolts, interlocking lugs, 11, 12, are provided at intervals along the parts, 7, 10, so as to engage when the blade, 7, is inserted and then moved longitudinally. Further

longitudinal movement is prevented by a spacing block between the end of the blade, 7, and the casing, the block being locked by a set screw. The edge, 8, of the blade may be grooved transversely.—W. F. F.

Mixing of powdered substances [explosives, etc.]. W. Dalton, Washington, D.C., U.S.A. Eng. Pat. 108,450, Sept. 7, 1916. (Appl. No. 12,692 of 1916.) Under Int. Conv., July 18, 1916.

Dry powdered ingredients are separately sifted on to a moving supporting surface in such a manner that they are deposited in successive thin layers of each ingredient, and the deposit is broken up and repeatedly re-layed. When highly sensitive explosives are to be mixed, the materials are wetted and the angle of the supporting surface so arranged as to prevent slipping of the ingredients. The material is sifted into a rotary hopper which discharges it on to the mixing surfaces, which are preferably conical. The hopper is sealed with a liquid to prevent any escape of powder.—J. H. P.

Roller mills. F. C. Bettison, and Greenwood and Batley, Ltd., Leeds, Eng. Pat. 109,116, Apr. 30, 1917. (Appl. No. 6087 of 1917.)

The pressure of the rolls in a roller mill is regulated and maintained by means of levers, the long arms of which carry weights, or alternatively by springs, in which case provision is made for adjusting the tension or compression.—J. H. P.

Catalyser and method of preparing the same. E. C. Kayser, St. Brelade's Bay, Jersey, Assignor to The Hydrogenation Co., Cincinnati, Ohio, U.S. Pat. 1,236,446, Aug. 14, 1917. Date of appl., June 12, 1914.

A NON-CATALYTIC compound of nickel is reduced by hydrogen in the presence of a relatively small proportion of copper.—W. H. C.

Recovering solvents; Apparatus for — F. Kniffen, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,236,719, Aug. 11, 1917. Date of appl., Oct. 16, 1912.

A CURRENT of gas is circulated by convection through an evaporating chamber and a condensing chamber situated below. The chambers are connected by vertical conduits, a cooling coil being located in the conduit leading from the evaporating

chamber to the condensing chamber, and a heating coil in the conduit by which the gas returns to the evaporating chamber.—W. H. C.

Evaporating apparatus. A. A. Dunham, Bainbridge, N.Y., Assignor to The Dry Milk Co. U.S. Pat. 1,236,825, Aug. 14, 1917. Date of appl., Oct. 24, 1916.

A ROTATING drying cylinder is partly surrounded by a hood provided with curved deflecting wings which have their concave sides opposed to the direction of a current of air which is passed between the cylinder and the hood. The dried material is removed from the cylinder by a scraper, and part of the heated air current is deflected as it leaves the discharge end of the hood so as to act on the material being removed from the cylinder.—W. H. C.

Vacuum: Method of producing —. I. Langmuir, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,237,210, Aug. 14, 1917. Date of appl., May 15, 1914.

THE residual gases left in an exhausted space are arranged to consist at least in part of hydrogen. Phosphorus pentoxide is then introduced into the partly exhausted space and metallic tungsten is rendered incandescent therein. The tungsten is partly vaporized and combines with the gases other than hydrogen forming solid products, whilst the hydrogen is rendered chemically active and is removed in part by combination with the tungsten and in part by oxidation by the phosphorus pentoxide.—W. H. C.

High vacua: Production and maintenance of — and the purification of noble gases. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 109,358, Dec. 14, 1916. (Appl. No. 17,983 of 1916.)

A RARE metal, for example thorium, is heated in an X-ray bulb which has been filled with dry air or nitrogen and evacuated to such an extent that a pure electron discharge can pass without positive gas ionisation. The metal glows and absorbs the gases, producing a vacuum so high that no gas ionisation effects can be observed when an electric current is transmitted. Impurities in argon, neon, and similar gases can be removed by filling the bulb with the gas and burning thorium in it.—J. H. P.

Homogenising liquids: Arrangement for —. W. G. Schröder, Lübeck, Germany. U.S. Pat. 1,237,222, Aug. 14, 1917. Date of appl., Aug. 26, 1916.

A CYLINDRICAL vessel, with a base of inverted conical form, is provided with a similarly-shaped inner concentric chamber which can be rotated by means of a vertical shaft. The inner chamber can also be raised or lowered inside the slightly wider containing vessel. The liquid to be homogenised is admitted by a side tube near the top and withdrawn through a lower side tube leading from the vertical stem below the conical base of the outer vessel.—J. N. P.

Separating liquids from solids in fluid suspension; Apparatus for —. A. L. Blomfield, Colorado Springs, Colo., Assignor to The Dorr Co. U.S. Pat. 1,237,715, Aug. 21, 1917. Date of appl., Nov. 13, 1915.

A SETTLING tank contains two inverted conical settling surfaces, one above the other, and of substantially the same diameter as the tank. The liquid containing suspended solid is fed to the upper part of the tank, and the solid material which settles on the conical surface is moved by rotating sweeps towards a central outlet pipe leading to the lower compartment. Similar sweeps are provided to move the solid material on the

lower surface towards a central outlet. Liquid is discharged from the upper and lower compartments by pipes at the side, the pipe leading from the lower compartment being provided with a regulating valve.—W. F. F.

Separating solid matters from fluids or fluids from fluids; Apparatus for —. F. E. Mass, Kilhey Court, nr. Wigan, and W. H. Smith, Wigan. Eng. Pat. 109,315, Sept. 11, 1916. (Appl. No. 13,026 of 1916.)

THE liquid or gas to be treated flows through a conduit which is provided with pockets which project inwards and act as baffles. The currents set up by these baffles cause the heavier or more viscous bodies to be deposited in the pockets.—J. H. P.

Condenser. A. K. Whitelaw, Woodriver, Ill. U.S. Pat. 1,237,818, Aug. 21, 1917. Date of appl., Apr. 24, 1917.

A CONDENSER consists of a pair of concentric cylinders, with a column of superposed horizontal baffle-plates inside the inner cylinder. The cooling liquid flows upwards through the annular space between the cylinders, overflows at the top into the inner chamber, and then flows downwards, falling from one baffle-plate to the next alternately at the centre and at the periphery. The vapour flows upwards through the inner chamber.

—H. J. H.

Concentrating liquids; Method of —. M. K. Serailian, Berkeley, Cal. U.S. Pat. 1,237,962, Aug. 21, 1917. Date of appl., Oct. 2, 1913.

LIQUIDS containing essential or aromatic ingredients are evaporated while flowing in a closed circuit, and the distillate is fractionally condensed. The first portion of distillate is returned to the concentrated liquid.—W. F. F.

Conveying materials [e.g., to metallurgical furnaces] by means of a current of air or other gas; Process of and apparatus for —. J. Westly, Christiana. Eng. Pat. 104,512, Mar. 1, 1917. (Appl. No. 31,059 of 1917.) Under Int. Conv., Feb. 21, 1916.

A CLOSED vessel maintained under constant pressure by means of compressed air is used as a reservoir for the material. The material drops from the reservoir into a conduit where it is carried along by a rapidly varying pressure of air. The variations of pressure are secured by a revolving valve in the conduit.—J. H. P.

Fumes; Apparatus for withdrawing — from confined spaces. J. A. Campbell, Annan, N.B. Eng. Pat. 109,338, Nov. 7, 1916. (Appl. No. 15,921 of 1916.)

AN ejector has two vertical inner nozzles, the lower orifice of the larger one being connected with a high pressure fan; the lower end of the smaller nozzle is bent at right angles to project some distance through the larger one, and is connected with the space from which the fumes are to be withdrawn. The high-velocity air current draws the fumes through the small nozzle.—J. H. P.

Filler bodies; Method of testing —. F. C. R. Marks, London. From Zahn Manufacturing Co., Buffalo, N.Y., U.S.A. Eng. Pat. 109,074, Aug. 25, 1916. (Appl. No. 12,067 of 1916.)

SEE U.S. Pat. 1,218,154 of 1917; this J., 1917, 494.

Furnaces and like structures. U. Wedge, Ardmore, Pa., U.S.A. Eng. Pat. 109,381, Jan. 24, 1917. (Appl. No. 1225 of 1917.)

SEE U.S. Pat. 1,208,217 of 1916; this J., 1917, 142.

Centrifugal apparatus for cleansing liquids. R. A. Sloan and J. E. L. Barnes, Liverpool. U.S. Pat. 1,239,731, Sept. 11, 1917. Date of appl. Nov. 7, 1913.

SEE Eng. Pat. 25,817 of 1912; this J., 1913, 1118.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Hydrogen sulphide; Liberation of — from gob fires in coal mines. T. J. Drakeley. Chem. Soc. Trans., 1917, 111, 853—863.

EXPERIMENTS were conducted showing that hydrogen sulphide is produced: (1) By passing sulphur dioxide over heated coal; (2) by heating mixtures of coal and sulphur; (3) by heating mixtures of coal and iron pyrites; (4) by passing water vapour over heated iron pyrites; (5) by passing hydrogen over heated iron pyrites. In each experiment the coal or iron pyrites was heated in a glass tube in an electric furnace to 500° C. The gases evolved were freed from tarry matter, dried by bubbling through concentrated sulphuric acid, and the hydrogen sulphide absorbed by copper sulphate acidified with hydrochloric acid. The presence of moisture in the stream of gases was found to increase the formation of hydrogen sulphide. It is concluded from these results that it is possible for iron pyrites to assist in the ignition of a gob fire, forming sulphur dioxide, and then for a series of reactions to take place during the initial stages of the fire whereby the sulphur dioxide is reduced and hydrogen sulphide is liberated.—L. A. C.

Flame; Uniform movement of — in mixtures of acetylene and air. W. A. Haward and S. G. Sastry. Chem. Soc. Trans., 1917, 111, 841—843.

MIXTURES of acetylene and air of known compositions were ignited in a tube 12 mm. in diameter and the speed of the flame was measured electrically between two points 40 cm. apart. The maximum speed was observed in mixtures containing 8—10% of acetylene, a rather higher percentage than the mixture for complete combustion (7.75% acetylene). In a 9 mm. tube the speeds were somewhat slower, but gave a curve (% acetylene—speed) of the same shape. The curves differed in shape somewhat from that described by Le Chatelier (see this Journal, 1896, 188) obtained by similar experiments. With a 25 mm. tube the duration of uniform speed was too short to admit of accurate measurement by the means employed.—L. A. C.

Utilisation of Italian products [petroleum and lar oils] in the preparation of benzol. Rodano. See III.

Action of coal gas on plants. II. Action on green plants. Wehmer. See XVI.

PATENTS.

Gas; Process of purifying —. W. O. Felt, Brooklyn, N.Y. U.S. Pat. 1,237,767, Aug. 21, 1917. Date of appl. Sept. 6, 1912. Renewed Nov. 1, 1916.

A HYDROCARBON gas is mixed with glycerin under a pressure of approximately 300 lb. per sq. in. and the temperature is then reduced to about 60° F. while under compression, whereby glycerin and impurities separate, and the gas is liberated in a relatively pure condition.—J. E. C.

Washing coke, breeze, and the like; Apparatus for —. A. L. Jennings, Cleckheaton. Eng. Pat. 108,955, Oct. 27, 1916. (Appl. No. 15,324 of 1916.)

COKE, breeze, or the like is delivered into the section, *i*, of a washer. The water is agitated by

a vaned roller, *o*, which also forces the floating material beneath the surface of the water. The refuse sinks to the bottom, being directed by the inclined plates, *b*², to a bucket elevator carried by the sprocket wheels, 16, and 9. The water passes

under the partition, *j*, and the floating, washed breeze is discharged through the opening, 5, by the alternate rise and fall of an ejector plate, *y*. The vaned roller, *o*, the bucket elevator, and the ejector plate, *y*, are operated simultaneously from the shaft, 1.—J. E. C.

Volatile organic bodies [cracked spiril, etc.]; Deodorising and clarifying —. W. A. Hall, London. Eng. Pat. 109,077, Aug. 26, 1916. (Appl. No. 12,100 of 1916.)

A TANK containing oil is arranged over a furnace, or as an alternative may be filled with superheated steam. Inside the tank is a series of columns so connected that they may be joined up in any order, and any one may be cut out as desired. The first of these is filled with Raschig rings of wrought iron, and is surrounded by a coil entering the column at the bottom; the others are packed with fullers' earth (flourine). The material to be heated (crude-cracked spirit, naphthalene, or fatty acids), is fed under pressure through the coil into the first column, which acts as a dephlegmator and pre-heater, and then into one or more of the other columns as desired. In order to heat the fullers' earth throughout, the vapours are passed through a triform series of pipes within the column to the lower end, and pass upwards through the earth to the outlet at the top. The temperature of the bath is maintained above the boiling point of the distillate required and any portions of higher boiling point collect at the bottom of the first column, whence they can be withdrawn. The vapours after treatment are passed through suitable condensing apparatus. By this process, the oil is not subjected to fractionation, and thus portions of different boiling points are condensed together, avoiding loss of valuable low boiling-point constituents.—L. A. C.

Paraffin wax: Treatment of — for the production of oxygenated and other compounds [fatty acids]. A. Schmidt, Troisdorf, Germany. Eng. Pat. 109,386, Feb. 13, 1917. (Appl. No. 2163 of 1917.)

PARAFFIN wax in a molten condition, at a temperature of 100°—120° C., is treated with a blast of air or oxygen for a prolonged period. The colour changes to light red, light yellow, reddish-yellow, and finally to a deep yellow. At this stage about 70% of the wax has been converted into a mixture of fatty acids, and small quantities of formaldehyde, alcohols, and the like. The different products are separated, e.g., by distillation, and the unchanged wax treated again. Mercuric oxide, or paraffin wax which has already been subjected to the treatment, may be used as a catalyst.—L. A. C.

Lubricating compounds: Process of making plastic —. E. F. Burch, Laurel Springs, N.J., Assignor to Crew Levick Co. U.S. Pat. 1,238,101, Aug. 28, 1917. Date of appl., June 16, 1916.

A PARAFFIN oil having approximately the physical properties of dodecane is mixed with an asphaltic oil, heated to 400°—450° F. (205°—230° C.), and air is blown through the mixture till it becomes plastic. The product is suitable for use in contact with water.—W. F. P.

[Petroleum] oils: Apparatus for dehydrating —. P. W. Prutzman, Berkeley, Cal. U.S. Pat. 1,238,331, Aug. 28, 1917. Date of appl., May 6, 1913.

A RETORT contains at the bottom a steam coil definitely spaced from it; preheated oil is fed on to this coil by means of a second coil having small apertures on the under side. The pressure in the retort is approximately atmospheric.—L. A. C.

Hydrocarbon vapours: Producing and treating — during the distillation of the same. J. H. Robertson, New York, Assignor to Robertson Motor Fuel Process Corporation. U.S. Pat. 1,238,339, Aug. 28, 1917. Date of appl., Apr. 25, 1916.

THE vapours produced during the distillation of crude oils are heated and subjected, under pressure, to a current of electricity, thereby increasing the yield of gasoline.—L. A. C.

Gasoline: Process for making —. S. Davidson, Buffalo, N.Y. U.S. Pat. 1,238,644, Aug. 28, 1917. Date of appl., Apr. 19, 1916.

NATURAL gas is compressed and mixed with a volatile liquid of low specific gravity; the mixture is then subjected to high compression and condensed. The condensed liquid is passed into a suitable storage tank and the hydrocarbon vapours are led off to be mixed with further natural gas before compression.—L. A. C.

Gas-producers: Working of by-product-recovery —. T. Rigby and G. W. Andrew, Dunfries, Scotland, Assignors to Wetcarbonizing, Ltd., London. U.S. Pat. 1,239,969, Sept. 11, 1917. Date of appl., May 7, 1914.

SEE Eng. Pat. 10,981 of 1913; this J. 1914, 852. The water used for the first stage of the cooling operation may be utilised for supplying steam to the air for the gas producer.

II B.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Flaming arc: Chemistry of the — in relation to luminescence. W. R. Mott, Amer. Electrochem. Soc., May, 1917. [Advance copy.] 16 pages.

THE subject is considered under the heads: (1) Comparison of carbon arc and flaming arc. (2) Magnified arc image (describing apparatus and method of investigation). (3) Colour of arc parts for nearly all elements. (4) Divided and diffused negative craters. (5) Volatility and crater distance. (6) Materials less volatile than carbon: pitting residues. (7) Typical characteristics for analytical purposes. (8) Light sources due to reactions with calcium fluoride in arc. (9) Effect of alkali salts on cyanogen bands. The following are among the more important conclusions drawn. From an electrochemical standpoint, the arc has considerable analogy to an electrolytic cell: the anode material moves to the cathode; the anode heat is probably due to a high resistance layer; the most electropositive elements, especially those with two or more high-temperature valencies (e.g., CaF, CaF₂) tend to give a bright arc shell due to chemiluminescence; and the electronegative (non-metallic) elements do not give light in a carbon arc as elements, but may do so as compounds. As regards the colour of different parts of the arc, in every case except with barium and vanadium, the core is blue or violet and the shell green, yellow, or red; no case of a blue arc shell is known. The easily reduced metals, excepting the iron (magnetic) group, give no arc shell, the lack of light being explained by the low energy of reaction at high temperatures. With a carbon arc, the flow of material is from positive to negative in nearly every case; but with salts of potassium, rubidium, and cesium in admixture with calcium fluoride, there is also a strong blast which comes from the negative crater, causing a marked dimness near the negative part of the arc. Dim negative craters, such as those produced by barium salts volatilised from the positive, are probably connected with nitrogen reactions at fairly high temperatures. The oxides of yttrium, zirconium, thorium, and other rare earth elements allow cratering, whilst beryllium oxide is the least volatile of the oxides which are so insulating as to inhibit cratering. Tungsten is easily the least volatile of all known elements, tantalum being second. The light sources of a yellow flame arc are due to reactions involving calcium fluoride, oxide, and carbide and elemental calcium, in addition to the usual carbon arc light sources.

—W. E. F. P.

PATENT.

Lamps: Cleaning and renewing electric (incandescence) —. F. G. Koyes, East Orange, N.J., Assignor to Cooper Hewitt Electric Co., Hoboken, N.J. U.S. Pat. 1,237,653, Aug. 21, 1917. Date of appl., Jan. 28, 1914.

FILAMENT lamps, which have been darkened or blackened by the spattering of material on the walls of the transparent portion, are cleaned by forming on the walls a volatile compound of tungsten, then removing the compound, and rinsing the lamp with air. A "restringent gas" is finally introduced.—B. N.

III.—TAR AND TAR PRODUCTS.

Benzol; Utilisation of Italian products [petroleum and tar oils] in the preparation of —. A. G. Rodano. *Annali Chim. Appl.*, 1917, 8, 7—11.

APART from illuminating gas, which is now used in Italy, to a limited extent, in the production of benzene, it would be possible to utilise, by a cracking process, crude petroleum from Ripi, and coal tar oils from which all benzene has been extracted, for the same purpose. In experiments to determine the yields from these products, the liquids were made to fall, drop by drop, into a retort, whence the vapour passed through a long tube which was packed with copper foil. This tube was heated to redness in a furnace, and was connected with a condenser. Coal tar oil freed from benzene and light oils distilling up to $170^{\circ}\text{C}.$ yielded, when cracked in this apparatus, a tar which, on distillation, gave 3.5% of light oils (b. pt. up to $170^{\circ}\text{C}.$), of which less than 2% boiling at $122^{\circ}\text{C}.$ was a mixture of benzene and toluene. Under the same conditions crude Ripi petroleum yielded about 10% of tar, rich in light oil. This had sp. gr. 0.810, and consisted of hydrocarbons rich in hydrogen. A mixture of equal parts of the original substances (coal tar oil and Ripi petroleum) gave about 7% (calculated on the original mixture) distilling up to $170^{\circ}\text{C}.$ Of this product 4.5% distilled up to $122^{\circ}\text{C}.$; 1.25% between 122° and $142^{\circ}\text{C}.$; and 1.25% between 142° and $170^{\circ}\text{C}.$ The fraction distilling up to $122^{\circ}\text{C}.$ consisted of a mixture of benzene and toluene, and yielded, on nitration, about equal parts of nitrobenzene and *o*-nitrotoluene. The yield thus obtained was about six times as great as that obtainable from an equal weight of coal.

—C. A. M.

Phenol and the cresols; Compounds of — with pyridine. W. H. Hatcher and F. W. Skirrow. *J. Amer. Chem. Soc.*, 1917, 39, 1939—1977.

THE authors draw attention to the fact that crude phenols must be extracted from coal-tar oils by means of sodium hydroxide before pyridine can be completely extracted by sulphuric acid, and they describe experiments conducted with a view to studying the extraction of mixtures of pyridine and phenol in benzene solution using pure materials. It was found that phenol can be extracted almost completely from benzene in presence of an equimolecular amount of pyridine by just sufficient sodium hydroxide to extract the same amount of phenol in the absence of pyridine, and if the pyridine be increased to four mols., the extraction of phenol is reduced by less than 5%; on the other hand, although if equimolecular amounts are treated with dilute sulphuric acid, the percentage extraction of pyridine is almost as great as though the phenol were absent, if four molecules of phenol are present, the extraction is reduced by about 75%. Freezing point curves for mixtures of pyridine with phenol, and *o*- and *p*-cresol indicated the formation of definite compounds by molecular association. The dissociation of these compounds in benzene and naphthalene solution was studied by the cryoscopic method, the compounds being present in equimolecular amounts, and it was shown that there is considerable dissociation, increasing rapidly with increased dilution.—L. A. C.

PATENTS.

Phenol; Manufacture of — [from cresols]. H. Terrisse, Geneva, Switzerland. Eng. Pat. 108,938, Oct. 4, 1916. (Appl. No. 14,118 of 1916.)

A MIXTURE of cresols is fused with a large excess of caustic soda (or potash) and treated with an oxidising agent, such as copper oxide, or peroxide of lead, manganese, barium, iron, or the like,

in order to convert the cresols into the corresponding hydroxybenzoic acids. The product may then be treated by one of two methods. (1) The fused mass is cooled on iron plates, pulverised, and heated to about $300^{\circ}\text{C}.$ in iron tubes through which a stream of carbon dioxide is passed. The phenol is condensed in suitable receivers. (2) The free hydroxybenzoic acids are isolated, dried, and heated in a still with crude anthracene oil to about $250^{\circ}\text{C}.$ when carbon dioxide is liberated and phenol distils over. This method is not so satisfactory as the first, owing to the large amount of acid required to neutralise the caustic alkali; also, in the first method, the residual alkali carbonate can be causticised and used again.—L. A. C.

Anthraquinone compounds. P. Nawiasky, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,238,932, Sept. 4, 1917. Date of appl., May 8, 1915.

SEE Ger. Pat. 288,464 of 1914; this J., 1916, 355.

Deodorising and clarifying volatile organic bodies [e.g., naphthalene]. Eng. Pat. 109,977. See II.A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Paper pulp; Waste products for —. G. E. Walsh. *Paper Making*, 1917, 36, 283—285.

THE by-product of the Indian corn (maize) crop in the United States offers an attractive raw material for paper manufacture, as, at the rate of one ton of corn stalks to the acre, the annual supply would be 100,000,000 tons, not more than one-third of which is put to practical use at the present time. The valuable part of the corn-stalk for paper making is the tough outer fibre, this portion being also of least value for cattle fodder. Thus by stripping the outer fibre a double purpose would be served, and the residue would be compressed into a concentrated form of fodder. Corn stalks have been used for rough paper and cardboard, but so far not for fine printing paper. Corrugated cardboard boxes made from corn stalk pulp are capable of replacing wooden boxes for the despatch of goods and would liberate a large amount of lumber for more important uses. Broom corn offers a more valuable raw material than ordinary Indian corn, the yield of fibre is much higher (42%), and the quality is suitable for the manufacture of white book papers. The quantity of broom corn stalks available, however, is only about 500,000 tons annually, and it is not certain what would be the effect on the broom industry if the crop were greatly enlarged. In the United States about 720,000 acres are devoted to rice cultivation, the yield of rice straw being about two tons to the acre, most of which is wasted. At present, only four paper mills are using the rice straw as a raw material, but the fibre, though short, is of excellent quality and produces paper of fine texture. The fibre lint which remains after the ginning of cotton is a valuable material which, although not suitable alone for the manufacture of paper, can be digested with corn stalks or broom corn and gives softness and improved texture to the paper. Cotton stalks are not a very promising material, but flax straw should become an important source of paper supply. There are about 2,500,000 acres devoted to flax seed cultivation in the United States, yielding over 3,000,000 tons of straw; as yet this material has not been utilised.—J. F. B.

PATENTS.

Woolen fabrics; Treatment of woven— to extract vegetable matter therefrom. F. H. Heppleston, Assignee of J. Nelson, Napier, New Zealand. Eng. Pat. 160,685, June 7, 1916. (Appl. No. 8069 of 1916.) Under Int. Conv., June 11, 1915.

WOOLLEN fabric, direct from the loom and while still in its greasy state, is heated in a "tenting" or drying machine to about 170° F. (77° C.) or higher, so as to render seed and other vegetable impurities brittle. The fabric is then fed immediately into an ordinary milling machine, the rollers of which are rotated at a suitable speed; the impurities are thus subjected to a crushing and rubbing action, causing them to be loosened and to fall out of the fabric.—J. F. B.

Yarn or the like; Apparatus for drying—. H. F. Anderton and G. Bailey, Bradford, Yorks. Eng. Pat. 108,681, Sept. 13, 1916. (Appl. No. 2322 of 1916.)

AN apparatus for drying hanks of yarn consists of a series of perforated cylinders or hollow rollers mounted within a closed chamber, the rollers being formed with comparatively large axial openings so that heated air may be circulated through them and out through the openings in their peripheries, from heating apparatus adjoining the chamber. The hanks are carried over the rollers by two series of tapes and are pressed in contact with the rollers while passing through the chamber, being subsequently delivered outside.—J. F. B.

Waterproof material and process of making same. Fibre product. J. McIntosh, Norristown, Pa., Assignor to Diamond State Fibre Co., Bridgeport, Pa. U.S. Pats. (A) 1,236,460 and (B) 1,236,461, Aug. 14, 1917. Dates of appl., (A) Apr. 25, 1916. Renewed July 5, 1917. (B) June 23, 1916.

(A) VULCANISED fibre is impregnated with a solvent of bakelite, e.g., alcohol, and the solvent is displaced by a condensation product of phenol and formaldehyde; the material is then heated to convert the condensation product into its solid form. The solvent employed may be used to displace the parchmientising agent in the freshly made vulcanised fibre and be then itself displaced by the condensation product. (B) Parchmientised fabric or fibre is impregnated with a modified oil, e.g., a sulphonated oil.—J. F. B.

Fibre product; Process of making a—. J. McIntosh, Norristown, Pa., Assignor to Diamond State Fibre Co., Elsmere, Del. U.S. Pat., 1,236,959, Aug. 14, 1917. Date of appl., Mar. 10, 1917. Renewed July 5, 1917.

PARCHMENTISED fibre is treated with a water-soluble material and then with a waterproofing substance which is soluble in the first material. The first treatment may be adapted to remove the water by displacement, and the waterproofing substance may be capable of rendering the impregnated fibre flexible.—J. F. B.

Acetylcellulose and process of making the same. W. G. Lindsay, New York, Assignor to The Celluloid Co. U.S. Pat. 1,236,578, Aug. 11, 1917. Date of appl., Apr. 8, 1911.

CELLULOSE is treated with a preliminary bath, e.g., hydrous acetic acid, which without altering the cellulose, acts so as to induce acetylation when the treated cellulose is subjected to an acetylating bath miscible with the preliminary bath; the treated cellulose is then subjected to the action of a non-solvent acetylating bath at 50°–80° F. (10.5°–26.5° C.).—J. F. B.

Acetylcellulose process and product. W. G. Lindsay, Newark, N.J., Assignor to The Celluloid Co. U.S. Pat. 1,236,579, Aug. 11, 1917. Date of appl., July 11, 1911.

CELLULOSE (100 parts) is impregnated with a mixture of 200 parts of 90% acetic acid and 50 parts of zinc chloride, and then acetylated with a mixture of 450 parts of acetic anhydride and 1650 parts of benzene. The cellulose is not hydrolysed by this treatment, and the acetylcellulose, which is soluble with difficulty in chloroform, retains the fibrous structure of the original cellulose.

Paper-stock from cereal straw; Process of making—. J. E. Lappen, Assignor to Winona Pulp and Paper Co., Winona, Minn. U.S. Pat. 1,236,723, Aug. 14, 1917. Date of appl., Apr. 21, 1916.

STRAW is boiled with water under pressure, and warm water is forced through the mass, whilst it is under pressure, to remove the gummy matter which has been liberated during the digestion; cold water is then forced through the mass while it is still warm and under pressure, to displace the gummy liquor without allowing it to become mixed with the cold water.—J. F. B.

Paper-making. [Sizing.] A. Brannon, Assignor to H. F. Marston, Dayton, Ohio. U.S. Pat. 1,237,864, Aug. 21, 1917. Date of appl., Oct. 22, 1912. Renewed Feb. 10, 1917.

A WEB of paper direct from the driers of the paper machine is immersed in size, the surface portions of the size are removed by squeezing, and the sized paper is subjected to cold until the size has become absorbed by and set in the paper, which is then dried.—J. F. B.

Sulphile liquor; Process of precipitating organic substances in—. H. B. Landmark, Drammen, Norway. U.S. Pat. 1,236,948, Aug. 14, 1917. Date of appl., Dec. 7, 1916.

THE organic sulphonic acid combinations contained in spent sulphile liquor are decomposed and precipitated by treatment with a stronger acid, e.g., sulphuric acid produced by the oxidation of the sulphurous acid contained in the liquor, by the discharge of electric sparks in presence of oxygen or air, or ozonised oxygen or air, within the vessel in which the liquor is under pressure and in which the precipitation takes place.—J. F. B.

Animal hair; Process of cleaning—and producing fertiliser. H. Y. McBride, Artesia, New Mexico, U.S.A. Eng. Pat. 109,149, Nov. 7, 1916. (Appl. No. 15,943 of 1916.)

SEE U.S. Pat. 1,218,573 of 1917; this J., 1917, 450.

Drying machines [for fabrics]. T. Allsop and W. W. Sibson, Mt. Airy, Pa., U.S.A. Eng. Pat. 109,322, Sept. 20, 1916. (Appl. No. 13,367 of 1916.)

SEE U.S. Pat. 1,198,377 of 1916; this J., 1916, 1105.

Paper; Process of manufacturing water-proof—especially for metallic styli. Kimpitsu-Seishi Kabushiki Kaisha, Ltd., and S. Kuroki, Tokyo, Japan. Eng. Pat. 109,200, Jan. 25, 1917. (Appl. No. 1288 of 1917.)

SEE U.S. Pat. 1,231,615 of 1917; this J., 1917, 1001.

Drying apparatus for use in drying fruit, vegetables, herbs, chemicals, powders, seeds, minerals, fibre, and the like. Eng. Pat. 108,915. See I.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Electrical endomose and adsorption. [Theory of dyeing.] T. R. Briggs, H. L. Pierson, and H. S. Bennett. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 11 pages.

THE relation between electrical endomose and the adsorption theory of contact electrification is discussed and it is shown that this theory provides a rational explanation of the phenomena. Experiments made with a modified form of Perrin's endosmometer confirmed the data accumulated by this author, and a careful study was made of the effect and temperature on the rate of electrical endomose. The results of some experiments with acid and basic dyestuffs, using an alundum diaphragm, are given, and it is shown that the phenomena encountered in dyeing are in accord with the ionic adsorption theory.—D. F. T.

PATENT.

Indigo fermentation-vat; Stable concentrated preparations for the —. A. Schmidt, Assignor to Farb- u. v. m. Meister, Lucius, und Brüning, Höchst, Germany. U.S. Pat. 1,239,526, Sept. 11, 1917. Date of appl., Nov. 13, 1914.

SEE Eng. Pat. 22,148 of 1914; this J., 1915, 1245.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Calcium carbonate; Solubility of — in boiling water. A. Cavazzi. Gazz. Chim. Ital., 1917, 47, II., 49—63.

EXPERIMENTS are described which show that calcium carbonate is slowly dissociated in boiling water, with the loss of carbon dioxide. Owing to this dissociation it is not possible to obtain a solution of calcium carbonate, by itself, in boiling water. The dissociation is inhibited in presence of about 15 c.c. of a cold saturated solution of lime per litre of boiling water in which the calcium carbonate is suspended. The substance which dissolves when calcium carbonate is boiled for a long time with water is practically entirely free lime, the quantity dissolved depending mainly on the volume of the liquid, the duration of the boiling, and the concentration of the solution. The addition of a small quantity of sodium carbonate (0.05 gm. per litre) is sufficient to prevent the dissociation by boiling water, and hence the solution of the calcium carbonate, so that the filtrate from the boiling liquid gives no turbidity with ammonium oxalate. When calcium carbonate is precipitated from aqueous solutions, it forms, even in the presence of free lime, supersaturated solutions, the stability of which depends mainly on the temperature and the concentration. —C. A. M.

Di-lead arsenate; Decomposition of — by water. C. C. McDonnell and J. J. T. Graham. J. Amer. Chem. Soc., 1917, 39, 1912—1918.

DI-LEAD arsenate, although only very slightly soluble in water, has been found to have a burning effect on tender foliage when used as an insecticide. Investigations were therefore made as to the action of large quantities of water on this compound. Quantities of the di-lead arsenate were treated under different conditions with freshly distilled water, the solid filtered off, and the filtrates tested. The proportion of arsenic to lead in these was found to be higher than in the original compound, indicating that arsenic acid was liberated and that minute traces of lead were

going into solution. A much smaller amount of lead was dissolved by hot water than by cold. Under certain conditions, e.g., when the compound was washed with cold running water, minute colourless transparent crystals were formed in the filtrate, and these, on examination, proved to be identical with crystals formed in the residues from the filters. This crystalline compound was found to be a basic lead arsenate (hydroxy-mimetite) having the formula, $Pb_4(PbOH)(AsO_4)_2 \cdot H_2O$.

—L. A. C.

Carbon dioxide and ammonia; Adsorption of — by charcoal. L. B. Richardson. J. Amer. Chem. Soc., 1917, 39, 1828—1848.

THE author has investigated the adsorption of carbon dioxide and ammonia by charcoal at pressures up to four atmospheres. In the case of carbon dioxide, equilibrium pressures were measured at twenty-one temperature points between -64° and 200° C.; in the case of ammonia, at seventeen points between -26° and 200° C. The results obtained show that, although below a pressure of 60 cm., the degree of adsorption is in fair agreement with the logarithmic isotherm equation suggested by Freundlich, $a = ap^{1/n}$ (a = vol. of gas adsorbed by one gram of charcoal at a given temperature; p = the equilibrium pressure, a = vol. of gas adsorbed at that temperature under a pressure of 1 cm., and $1/n = [d \log a] / [d \log p]$, a constant), above that pressure the adsorption rapidly decreases, indicating a maximum value for each temperature point. In the case of carbon dioxide, no evidence was obtained of the formation of a chemical compound such as that obtained by Rhead and Wheeler (this J., 1913, 276) in the adsorption of oxygen by charcoal, but in the adsorption of carbon dioxide at low temperatures, certain phenomena suggest that a small quantity of the gas may be absorbed in the charcoal structure.—L. A. C.

Acid-resisting properties of some iron-silicon alloys. Kowalke. See X.

PATENTS.

Ammonium sulphite; Process for oxidising — to ammonium sulphate. Elektrizitätswerk Lonza, Gampel, Switzerland. Eng. Pat. 105,906, Mar. 21, 1917. (Appl. No. 4113 of 1917.) Under Int. Conv., Apr. 25, 1916.

CALCIUM sulphate is employed as an oxygen carrier to accelerate the oxidation of ammonium sulphite by air and prevent loss of ammonia. The process depends on the formation, by double decomposition, of calcium sulphite which is more rapidly oxidised than the corresponding ammonium compound.—W. E. F. P.

Sulphate of ammonia; Production of neutral —. F. Capron, Barcelona, Spain. Eng. Pat. 108,990, Dec. 8, 1916. (Appl. No. 17,648 of 1916.)

IMPURE, acid crystals of ammonium sulphate obtained by the usual processes are washed with a saturated, neutral or slightly alkaline solution of ammonium sulphate until free from acid, and then centrifuged.—W. E. F. P.

Cyanides and ammonia; Process of manufacture of —. L. P. Devauelle, Courbevois, France, and F. Bensa, Genoa, Italy. U.S. Pat. 1,237,185, Aug. 21, 1917. Date of appl., Sept. 9, 1915.

A SUITABLE reaction mass is heated in a retort through which nitrogen is passed to form cyanides. A current of steam is then substituted for the nitrogen; ammonia is thus formed, the temperature of the charge being reduced sufficiently to

prevent the production of cyanates and dissociation of the ammonia, without lowering appreciably the temperature of the furnace and retort.

—J. B. C. K.

Ammonia-oxidation process. C. Ellis, Montclair, N.J. U.S. Pat. 1,237,884, Aug. 21, 1917. Date of appl., Jan. 2, 1917.

AMMONIA and a gas containing oxygen, e.g., air, are brought into contact with an oxidising catalyst containing a compound of silver with an oxygen compound of another element, e.g., silver molybdate. Oxides of nitrogen are produced.

—J. B. C. K.

Spent iron oxide; Furnace for the treatment of —. J. Kershaw, London. Eng. Pat. 108,980, Dec. 1, 1916. (Appl. No. 17,280 of 1916.)

THE apparatus consists of one or more inclined flues, each provided with a feeding device at the upper and discharging means at the lower end. The flues may be arranged one above the other, in spiral form, around a central column, the inclination being such that the spent oxide remains in repose upon the floor of each until the sulphur is expelled, when the residue travels downwards by gravity to the place of discharge. A common collecting flue for the sulphurous gases is provided at the top of the furnace.—W. E. F. P.

Aluminium fluoride; Process for obtaining —. C. A. Doremus, New York, Assignor to J. S. Hoyt, Darien, Conn. U.S. Pat. 1,237,488, Aug. 21, 1917. Date of appl., Feb. 21, 1913.

FELSPAR is treated with 20% hydrofluoric acid to produce soluble aluminium fluoride and hydrofluosilicic acid and insoluble alkali fluosilicate. The mixture is filtered, and the hot solution treated with aluminous material to decompose the hydrofluosilicic acid, after which the liquid is again filtered and evaporated to dryness to recover aluminium fluoride.—W. E. F. P.

Calcium arsenate; Process of making —. G. R. Riches and W. C. Piver, Hoboken, N.J. U.S. Pat. 1,237,815, Aug. 21, 1917. Date of appl., Oct. 27, 1916.

CALCIUM hydroxide is treated with arsenic acid in the presence of an independent electrolyte, such as sodium hydroxide, which prevents the occlusion of a soluble compound of calcium and arsenic by the calcium arsenate formed as a result of the reaction.—J. B. C. K.

Oxide of tin; Process for the direct production of pure —. J. Terwelp, Neuss, Germany. U.S. Pat. 1,237,810, Aug. 21, 1917. Date of appl., Sept. 3, 1914.

A TIN-BEARING material is heated in the presence of a gaseous reducing agent, but in an oxidising atmosphere, to at least the reduction temperature of tin oxide, without producing a melt. The tin vapour formed by the reaction is immediately oxidised and leaves the charge as oxide fumes.

—J. B. C. K.

Iodine; Processes for producing —. R. L. Datta, Calcutta. Eng. Pat. 108,918, Sept. 12, 1916. (Appl. No. 12,878 of 1916.)

THE process depends on the decomposition of gaseous hydrogen iodide by nitrous gases, and the re-oxidation of the resulting nitric oxide by air. Since hydrogen chloride and bromide are not similarly decomposed, the iodine obtained by this means is free from other halogens. In practice, gaseous hydrogen iodide, air, and nitrous gases, at ordinary temperature, are conducted through separate inlets into a glazed earthenware chamber, the iodine being deposited in crystals on the walls;

or a current of air and nitrous gases (3 to 1 by volume) is passed over a slowly heated mixture of dry alkali iodide and sulphuric acid (or sodium bisulphate) in molecular proportions, the liberated iodine being condensed, and the escaping gases mixed with air for further use.—W. E. F. P.

Alkali metal compounds; Process of obtaining from mineral silicates and other materials containing alkalis. A. Mond, London. From W. A. Schmidt, Los Angeles, Cal., U.S.A. Eng. Pat. 109,105, Sept. 5, 1916. (Appl. No. 12,581 of 1916.)

SEE U.S. Pat. 1,200,887 of 1916; this J., 1917, 32. The process may be used for recovering potassium and like compounds as a by-product in cement manufacture.

Production and maintenance of high vacua and the purification of noble gases. Eng. Pat. 109,358, Sec I.

VIII.—GLASS; CERAMICS.

PATENT.

Kiln-baked articles; Method and means for coating —[with glaze]. J. W. Ivory, Assignor to Clay Products Co., Brazil, Ind. U.S. Pat. 1,237,520, Aug. 21, 1917. Date of appl., Jan. 22, 1917.

THE glaze material in the form of slip is fed into a horizontal tube fixed in the side of a kiln. Inside this tube is fixed axially a pipe terminating in a nozzle and connected with a supply of compressed air. The blast of air issuing from the nozzle carries the glaze material in the form of a cloud of spray into the kiln and so coats the charge.—H. J. H.

IX.—BUILDING MATERIALS.

Bauxite for lining furnaces. N. Lecesne, La Céramique, 1917. Eng. and Min. J., 1917, 104, 417.

A MIXTURE of anthracite (1 part) and crude bauxite as quarried (3 parts) is charged into a hot furnace, lined with fused bauxite. Air at an initial pressure of 40 in. water gauge is blown through and the charge rapidly heats up. The pressure rises and may reach 400 in., though usually 160 in. water gauge is the maximum attained. The bauxite gives up its water suddenly and is thereby disintegrated. Aluminium carbide is produced and burns later, raising the temperature to 3000° C. Silica is volatilised. Iron oxide is reduced to metallic iron which is expelled by the air blast with the production of a shower of sparks. The blast is continued so as to burn out excess of carbon and cool the purified product, which can then be used in the manufacture of refractory bauxite bricks.—H. J. H.

PATENTS.

Wood impregnation. H. G. Jennison, Toledo, Ohio. U.S. Pat. 1,237,521, Aug. 21, 1917. Date of appl., May 20, 1915.

THE wood is steamed, superficially impregnated by submersion under increased hydraulic pressure, and the impregnating liquid is then distributed throughout the mass by exposure to increased gaseous pressure. On releasing this gas pressure, the excess of liquid is exuded from the pores of the wood.—H. J. H.

Asphalt limestone: Process of producing synthetic — C. L. V. Zimmer, Berlin-Wilmersdorf, Germany. U.S. Pat. 1,237,852, Aug. 21, 1917. Date of appl., Aug. 11, 1915.

POWDERED limestone or the like is added to an aqueous emulsion of bituminous material, and the stone-like product is heated to 150–200° C. —H. J. H.

Refractory material, and process of making the same. H. A. Kennedy, Clearfield, Pa. U.S. Pat. 1,238,020, Aug. 21, 1917. Date of appl., Nov. 28, 1916.

A BASIC refractory material is produced in clinker form by subjecting an intimate mixture of lime, magnesia, silica, and an oxide fluxing agent to a high temperature in a rotary kiln, in such proportions that the product contains 78–92% of calcium and magnesium oxides and 2–13% of silica in addition to the oxide fluxing agent.—H. J. H.

Impregnating artificial and natural materials [wood, stone, fabrics, etc.]: Process of — B. Schwerin, Assignor to Elektro-Osmose A.-G. (Graf Schwerin Ges.), Frankfurt, Germany. U.S. Pat. 1,238,202, Aug. 28, 1917. Date of appl., Aug. 23, 1916.

Process of obtaining alkali metal compounds from mineral silicates and other materials containing alkalis. Eng. Pat. 109,105. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ores: Present knowledge and practice in regard to the briquetting of — G. Barrett and T. B. Rogerson. Iron and Steel Inst., Sept., 1917. [Advance copy.] 42 pages.

THE processes may be subdivided into four classes: (A) Those in which cohesion is brought about by pressure. The most widely used is the Bonay process. (B) Those in which the ore is pressed, with or without addition of a binder (e.g., lime or clay), and subsequently heated to incipient fusion or vitrification. The Gröndal process is the most satisfactory of this class. (C) Those in which the ore is mixed with a binder, pressed into moulds, and hardened in air, steam, or gas. Magnesium chloride is used in the Schumacher process, granulated slag and lime in the Stütz process, and sulphite-cellulose waste liquor or sulphite pitch in the Trainer, Pioneer, and Pollack processes. (D) Those in which the material is agglomerated by heat alone. The most widely used process is that of nodulising in rotary kilns, which are usually fired with pulverised coal, though oil, producer gas, and blast-furnace gas are also used. The so-called sintering processes include the Dwight-Lloyd, the Huntington-Hieberlein, the Greenawalt, and the West process. As regards the suitability of the various processes for iron ores, those of class A are not likely to produce satisfactory briquettes for the blast furnace, and are expensive to work. Those of class B (e.g., the Gröndal process) can be made to yield suitable products. In class C, the Schumacher process is probably the cheapest of the true briquetting processes, and appears to have

been successful in a number of works. The disadvantage of all true briquetting processes is, that in at least one stage every briquette must be moved by hand, entailing heavy labour cost and risk of breakage. The rotary kiln has a large capacity, is not subject to royalty, and needs little labour. It is effective for reducing the amount of sulphur in the ore, but requires careful working, as rings of clinkered ore are liable to form in the hottest part of the kiln. Sintering has been widely adopted in America owing to its reputed low cost of operation, simplicity, and wide range of applicability. The sintered material is strong and stands weathering and stacking well. Experiments should be made with every new material upon a small scale before agglomerating plant is installed to treat it. Comparative costs at pre-war prices are given, and descriptions of briquetting machines and coal pulverising plant. —W. R. S.

Phosphorus; Determination of — in cast iron. A. Cavazzi. *Annali Chim. Appl.*, 1917, 8, 1–6.

ABOUT 5 grms. of the finely-divided sample is boiled with dilute nitric acid (1:1) until nitrous fumes are no longer evolved, and the solution is treated with 15 to 20 c.c. of dilute sulphuric acid (8 to 9 c.c. of strong acid), and gently boiled until white fumes appear, the heat being then regulated so that the temperature of the ferric sulphate does not exceed 210° C. (decomposition temperature 350° C.). When the evolution of white fumes has practically ceased, the residue is powdered, again heated, and then cooled, and treated with 40 c.c. of a mixture of 5 c.c. of strong nitric acid, 20 c.c. of strong hydrochloric acid, and 15 c.c. of water, and the liquid gently boiled until concentrated to about a third of its volume. It is then diluted with 50 c.c. of water, cooled, and filtered, and the residue washed six times with boiling water acidified with nitric acid. The filtrate is evaporated until viscous, and then treated with about 4 c.c. of nitric acid, to expel any trace of hydrochloric acid, the mass being constantly stirred during the moderate heating. It is next cooled and treated with 30 c.c. of dilute nitric acid (15 c.c. of acid of sp. gr. 1.153 diluted to 30 c.c. with water), and heated for a few minutes to dissolve the ferric sulphate. The solution is mixed with a solution of 15 grms. of ammonium nitrate in 25 to 30 c.c. of water, boiled, and treated with 50 c.c. of a boiling solution of 2.0 to 2.5 grms. of ammonium molybdate, the mixture being well stirred, and then kept at about 80° C. for 30 mins. The supernatant liquid is decanted, and the phosphomolybdate precipitate washed four times with a solution of 25 grms. of ammonium nitrate and 20 c.c. of nitric acid (sp. gr. 1.153) in 500 c.c. of water, then dissolved in 10 c.c. of dilute ammonia solution (1:2), and the solution treated with a solution of 5 grms. of ammonium nitrate in 20 c.c. of water, and 1 gm. of ammonium molybdate in 30 c.c. of water, heated to incipient boiling, and treated with 20 c.c. of boiling nitric acid (sp. gr. 1.153). The re-precipitated phosphomolybdate is washed with ammonium nitrate solution, and dissolved in ammonia solution (1:4), and the solution treated with dilute hydrochloric acid (1:3) until the precipitate begins to appear again, when 10 to 20 c.c. of magnesia mixture is added, and the liquid heated to boiling, and treated, drop by drop, with dilute ammonia solution, with constant stirring, until a slight turbidity appears. The liquid is then cooled, and treated with sufficient strong ammonia solution to increase the original volume by a fifth or a fourth, and the precipitate of ammonium magnesium phosphate separated and converted into magnesium pyrophosphate in the usual way.—C. A. M.

Iron; Microstructure of commercially pure—between A_1 and A_2 . W. J. Brooke and F. F. Hunting. *Iron and Steel Inst.*, Sept., 1917. [Advance copy.] 7 pages.

IN an investigation to determine the causes of the characteristic red-shortness exhibited by "Armco" iron (99.84% Fe) when subjected to mechanical treatment between 900° and 800° C., pieces of the metal were heated to well above the upper critical point and allowed to cool very slowly to temperatures ranging between 1040° and 575° C., when they were immediately quenched and examined mechanically and micrographically. The brittleness exhibited by the hot metal was entirely absent in the quenched specimens. The microstructure varied with the quenching temperature. The piece quenched from 1040° C. had the character of γ -iron with "martensitic" appearance, the crystal boundaries being well broken up and showing small, crystalline grains. This structure slowly altered with the lowering of the quenching temperature, the γ -iron effect changing into a more definite ferrite form with crystal grains gradually increasing in size. At about the A_1 point (900° C.) the ferrite grains had increased considerably in size, and at the junctions of many of the crystal boundaries a constant and characteristic structure appeared, consisting of a clearly defined, more or less pearlitic area or lake, surrounded by ferrite and then by a definite boundary with which the adjacent crystal grains were connected. As the quenching temperature was lowered, this structure became gradually less pronounced until, at just above 800° C., it ceased to exist. It would thus appear that, between the A_1 and A_2 points, iron of the relative purity stated possesses the property of throwing out of solution an eutectoid (probably composed of iron carbide, phosphide, and sulphide, with traces of manganese sulphide and ferrous oxide), and that the pronounced red-shortness of the metal between these temperatures is due to or connected with this cause.—W. E. P. P.

Corrosion of cast iron, and its bearing upon the electrolytic theory of corrosion. E. A. and L. T. Richardson. *Amer. Electrochem. Soc.*, May, 1917. [Advance copy.] 6 pages.

MEASUREMENTS were made on the corrosion of samples of grey cast iron, a low carbon steel, and a commercial pure iron, which were found by chemical analysis and by photomicrographs to possess a wide range of heterogeneity in the different cases. The test pieces were carefully annealed at 750° C., and, after removing the surface oxide coating by filing, were weighed. After exposure to the atmosphere for one month, the pure iron had undergone the least corrosion, while cast iron and steel seemed about equal, and decidedly more corroded than pure iron. The rate of rusting of the cast iron decreased later, and after four months the cast iron appeared about equal to the pure iron, while steel was much more oxidised than either. At the end of seven months the test pieces were cleaned with neutral ammonium citrate and re-weighed. The losses, computed in grms. per sq. cm., were: cast iron, 0.966; steel, 1.546; pure iron, 0.771. No difference could be detected between the cast iron and the pure iron as regards the condition of the surface, the depth of the pits, and the uniformity of rusting. The steel was, on the other hand, very deeply pitted, and the rusting on the surface was irregular. These results agree with the experiments of other observers in showing that the resistance of iron to corrosion does not necessarily depend on its purity or homogeneity, as would be expected from the electrolytic theory of corrosion, and indicate that while initial rusting may be largely electrolytic in character, factors such as the adherence

of rust and the protection thereby given to the metal come into operation and outweigh any electrolytic corrosion.—J. N. P.

Groves-Echells electric [steel] furnace. E. K. Scott. *Met. and Chem. Eng.*, 1917, 17, 243—245. (See also Eng. Pat. 106,626 of 1916; this J., 1917, 891.)

THE rectangular furnace body with a curved base is made of boiler plate with a thick conducting hearth of magnesite, and is supported on grooved steel rollers. By means of a screw and gear wheels the furnace with its electrodes can be tilted backwards and forwards. The dome-shaped roof is made of silica bricks set in a steel frame and made as low as possible so as to reduce the wasting away of the electrodes by the action of the hot furnace gases. A roof will last about 100 heats, and a duplicate one is provided with each furnace to ensure continuity of operation except during the time required for changing the roof. The electrodes pass vertically downwards through apertures in the roof so that arcs can be maintained on the slag and the surface of the molten metal. Each electrode is secured in a bronze or steel holder attached to, but insulated from, a steel jib, projecting from a wheeled carriage. The carriage travels up and down a vertical mast, which is made of two channel sections bolted to the side of the body. With a three-phase current, two of the phases are connected to electrodes above the bath, and the third phase to a copper plate below the conducting hearth. About 12% of the total energy is used in the hearth, and the heat is thus favourably distributed in the lower part of the furnace. The hearth lining is at least 20 in. thick and is constructed of dolomite and magnesite so as to give a graded resistance, this being high on the inside in proximity to the charge and decreasing rapidly towards the outside. The high-tension electric supply is transformed by means of a delta star system of connections to low tension. Short-circuiting of the electrodes is guarded against by the permanent resistance in the path of the current through the hearth and by arranging the connections so that the short-circuit current of one electrode must traverse two transformers in series and in different phase, thus automatically lowering the power factor temporarily. When pouring the metal by tilting the furnace, the spout is arranged to descend in a vertical line by means of compensating rollers which move the furnace bodily forward during the tilting. The capacity of a 260 K.V.A. furnace, which takes 2 graphite electrodes, of 1 in. diam., is $\frac{1}{2}$ ton, and a 2600 K.V.A. furnace, using 1 electrodes of 10 in. diam., has a capacity of 12 tons. When working charges of steel scrap and iron ore, after melting, fluorspar is added in order to eliminate the phosphorus. After the phosphate slag has been skimmed off, a new slag is made by addition of high-grade lime, fluorspar, and white sand, in the proportions of 30, 10, and 5, and a small quantity of powdered anthracite is spread on the slag produced. An atmosphere of carbon monoxide is thus maintained and decoxidation of the steel is brought about through constant reduction of silicon from the slag and may be hastened by the addition of small quantities of ferrosilicon.—J. N. P.

Steel; The Eggertz test for combined carbon in —. J. H. Whiteley. *Iron and Steel Inst.*, Sept., 1917. [Advance copy.] 101 pages.

INVESTIGATION of the carbon dioxide content of the gases given off in the Eggertz test showed that carbon dioxide is given off at a decreasing rate during several hours, in amounts closely proportional to the carbon content of the sample and irrespective of its previous heat treatment, except in the case of austenitic steels. Hydrocyanic acid

is also evolved during solution of the sample; its amount showed unaccountable variations, and was independent of the heat treatment and the manganese or nitrogen content of the steel. Only a minute quantity of hydrocarbon (and possibly also carbon monoxide) is evolved when the test solution of either a normal or a quenched steel is heated. Thus a steel containing 1% of combined carbon when submitted to the Eggertz test would yield in the first 10 minutes 22% of the carbon as dioxide, 5–10% as hydrocyanic acid, and 2–3% as hydrocarbons. The carbon not accounted for was not evolved as a gaseous compound, but was present in the nitric acid solution as a colourless compound or compounds. The colouring matter is formed by the subsequent solution, in the nitric acid, of the brown precipitate that remains when the metal is attacked. It was separated by dialysis into a brown colloidal solution within the dialyser, and a yellowish-green solution in the outer vessel. The colouring matter in the yellowish-green solution slowly changes to a colourless or slightly coloured compound on continued boiling of the test solution. Variations in the colorimetric results are shown to be due to at least two causes: delay in the solution of the brown precipitate, and early formation of excess of colourless products. The two actions may overlap, and their separate effects cannot often be ascertained. The particles of the brown precipitate resemble in shape those of the carbide from which they are formed: as the particles of carbide decrease in size, the precipitate becomes more gelatinous and yields greener tints. The colour of the test solution is also affected by an electrolytic action set up during solution between the iron and the carbide embedded in it; and since larger carbide particles remain in contact with the metal for a greater length of time, the effects of cold-work and quenching affect the colour; drillings, for example, give higher results than cut pieces of the same steel. No simple relation could be found between the Eggertz results and the Brinell hardness of quenched steels, or those quenched and tempered at various temperatures. By adding 15 c.c. of sulphuric acid (1:3) to the cooled test solution before matching the colour, it was found possible greatly to reduce variations in the tints, though a perfect match could not be obtained in all cases.—W. R. S.

Steel; Electrolytic pickling of—. M. de K. Thompson and O. L. Mahman. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 6 pages.

A COMPARISON was made of the consumption of acid and amount of iron dissolved in the chemical and electrolytic methods of removing scale from steel plates. In the chemical treatment the plate was immersed in a boiling solution of about 5% sulphuric acid until the surface was free from scale. In the electrolytic method, the plate was used as cathode with a lead anode in a solution of sulphuric acid (1·2 sp. gr.) at 60° C.; the current density was 40–60 amps. per sq. foot. In both cases the solution was concentrated until the detached scale had all dissolved, and the iron was estimated by reducing and titrating with potassium permanganate. The ratio of the amount of iron dissolved in the electrolytic method to that in the chemical method was about 0·6:1·0, and the saving of iron and acid in the former method was found to be as great as the cost of power required for the electrolysis. The cathodic reduction of magnetic oxide of iron was investigated by conducting electrolyses with cathodes of fused magnetite, and estimating the amount of hydrogen evolved comparatively with that obtained when using a metal cathode with the same current.

The reduction was found to be most efficient at a temperature of about 50° C., and with a current density of 50 amps. per sq. foot.—J. N. P.

Molybdenum and vanadium in steel; Volumetric determination of—. Travers. Comptes rend., 1917, 165, 362–364.

THE steel is dissolved in dilute sulphuric acid, the ferrous sulphate oxidised by the addition of powdered potassium permanganate, avoiding an excess, the mixture is then rendered alkaline with potassium hydroxide, boiled, and filtered. An aliquot portion of the filtrate is diluted, faintly acidified with hydrochloric acid, and treated with an excess of standardised titanium trichloride solution; the excess is then titrated with ferric chloride solution, using potassium thiocyanate as indicator. In solutions containing less than 0·05 grm. of molybdenum per litre and having an acidity corresponding with 1 c.c. of free HCl per 100 c.c., the reduction proceeds according to the equation: $2\text{MoO}_3 = \text{Mo}_2\text{O}_3 + \text{O}$. Vanadium may be determined in a similar way, the reduction being according to the equation: $\text{V}_2\text{O}_5 = \text{V}_2\text{O}_4 + \text{O}$. If molybdenum and vanadium are both present in a steel, they are determined together as described: the vanadium is then determined colorimetrically (with hydrogen peroxide), and the molybdenum is obtained by difference.—W. P. S.

Iron-silicon alloys; Acid-resisting properties of some—. O. L. Kowalke. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 6 pages.

A NUMBER of iron-silicon alloys, containing 1·2 to 19·8% Si, were immersed in 10% solutions of sulphuric, hydrochloric, nitric, acetic, and citric acids for periods ranging from 51 hrs. to 29 days at 20–35° C., and the losses determined. With few irregularities, the resistance to acid attack was a minimum at 1·2 to 3·3% Si, and a maximum at 16–18% Si. The alloys were made from electrolytic iron and ferro-silicon, melted together in graphite crucibles lined with magnesium oxide, and cast in a graphite mould. The alloys of low silicon content made good soft castings, but above 3·5% Si the alloys were brittle; the test-pieces of the brittle alloys were ground to obtain a fairly smooth surface. The alloys containing 3 to 5% Si were not excessively brittle, but were very readily attacked by sulphuric, hydrochloric, acetic, and citric acids. The alloys containing 16 to 18% Si were exceedingly resistant to mineral acids, but were so brittle that they could not be machined.—J. H. P.

Brasses; Experiments on the fatigue of—. B. P. Haigh. Inst. of Metals, Sept., 1917. [Advance copy.] 23 pages.

EXPERIMENTS were made with samples of Muntz metal, naval brass, and phosphor bronze, to ascertain the effects of annealing, using stresses alternating between equal intensities of direct pull and push; to determine the relation between the limiting range of stress required to produce fatigue, and the ratio between the maximum and minimum stresses; to study the phenomena of elongation under stresses greater than the fatigue limit, but less than the ultimate tensile strength of the material; and to study the influence of corrosive agents on the endurance of the alloys under alternating stress. Under alternating stresses varying between equal intensities of pull and push, with a frequency of 2000 per min., the behaviour of the alloys was very similar to that of mild steel under the same conditions; but the limiting fatigue stresses were rather lower, the results more consistent with different specimens of the same

sample, and the fractures somewhat more regular in profile. Under the higher ranges of stress, the metal became warm and soon failed by cracking on a plane perpendicular to the axis of stress; under the lower ranges, the heating effect was imperceptible to the touch, and the endurance increased to millions of cycles before fracture occurred in the same manner. The most regular and useful ratio of comparison appeared to be that between the limiting fatigue stress and the ultimate strength of the metal, this ratio being highest in those metals showing a considerable reduction of area at fracture in the tensile test. The elongations produced by pulsating and steady stresses were found to be of the same nature, the yield point and form of stress-strain diagram of specimens extended first under pulsating and then under steady stresses being the same as for those extended under steady stress alone, and conversely. As regards the influence of corrosive agents, the endurance of annealed Muntz metal and of unannealed naval brass was not affected by superficial etching of the specimens with ammonia before testing, but much reduced when the specimens were tested in the presence of this reagent. On the other hand, the endurance of these alloys when moistened with dilute hydrochloric acid was generally greater than that of the dry specimens under the same ranges of stress, and the fatigue of phosphor bronze was not appreciably accelerated by the presence of either of these reagents or sea water.—W. E. P. P.

Etching agent [for brass and bronze]: Chromic acid and hydrogen peroxide as an —. S. W. Miller. *Inst. of Metals*, Sept., 1917. [Advance copy.] 3 pages.

A FEW drops of a strong solution of hydrogen peroxide are added to a very dilute solution of chromic acid. The specimen is immersed and kept moving in the solution for a few seconds; it is then removed and washed immediately in running water. The reagent is equally satisfactory for all brasses and bronzes, giving much better results than chromic acid alone.—W. R. S.

Aluminium sheet: Effects of heat at various temperatures on the rate of softening of cold-rolled —. H. C. H. Carpenter and L. Taverner. *Inst. of Metals*, Sept., 1917. [Advance copy.] 41 pages.

SEVERELY cold-worked aluminium sheet was subjected to temperatures from 550° to 100° C. over periods of from 1 to 2618 hours, and the loss of work hardness determined at stated intervals by measuring the tenacity and percentage elongation. Heating at 550 to 300° C. caused a very rapid softening of the metal. Over this range, softening was complete in 96 hours, and occurred almost entirely during the first hour at temperatures from 550° to 350° C. At 250° C. the rate of softening was much less rapid, 600–800 hrs. being required for completion, and the same ultimate value for tenacity was obtained as at higher temperatures. From 200° to 100° C. the rate of softening was slow, especially as the latter temperature was approached. A comparatively rapid fall in tenacity occurred during the first hour, after which there was a tendency for the tenacity to cease falling or actually to rise, this period being completed in 100 hrs. in most cases. A relatively very slow fall of tenacity then commenced and was steadily maintained at a rate indicating that from 1 to 3 years would be required for complete softening to be effected. Throughout the series of experiments, no increase of tenacity was observed to result from heating the metal, which thus differs from cold-worked brass and copper. While at

variance with A. Le Chatelier's fourth law of annealing (*Congr. Int. Méthodes d'Essai des Mat. de Construction*, 1901, 2, 1–25; compare this J., 1896, 455), this result is in agreement with Beilby's view—that between the hard and soft states a mechanically unstable condition exists in which the loss of stability is not compensated by the development of plasticity, which only occurs when the whole mass consists of properly developed crystals. The results obtained are regarded as indicating the practicability of employing cold-rolled aluminium for industrial purposes requiring temperatures up to 200° C., especially if such temperatures are only attained intermittently.

—W. E. P. P.

Silver: Addition agents in the electro-deposition of — from uncommon silver salts. F. C. Mathers and T. G. Blue. *Amer. Electrochem. Soc.*, May, 1917. [Advance copy.] 3 pages.

SILVER perchlorate, fluosilicate, fluoride, and ethylsulphate were electrolysed in baths containing glue, peptone, gum arabic, and other addition agents; the deposits were somewhat better than from nitrate baths containing the same addition agents. Phenolsulphonic acid, cresolsulphonic acid, and their sodium or ammonium salts, sodium naphthalenesulphonate, and sodium benzenesulphonate, when added, to the extent of 3% in each case, to the silver baths, including the nitrate, restrained the formation of crystals in the same manner as, but less effectively than, tartaric acid. The use of uncommon salts of silver does not seem to offer possibilities of obtaining much better deposits than those obtained from nitrate baths.

—B. N.

Hydrogen: Evolution of — from cyanide plating solutions. O. P. Watts and A. Brann. *Amer. Electrochem. Soc.*, May, 1917. [Advance copy.] 6 pages.

EXPERIMENTS were made with silver and copper cyanide solutions, with the addition of varying amounts of free potassium cyanide, in order to determine the effect of the latter on the liberation of hydrogen at the cathode. The effect was found to be much greater with copper than with silver solutions. The liberation of hydrogen is direct, and is not due to the solvent action of the free cyanide on the metal, but to the raising of the potential necessary to deposit the metal until it reaches or exceeds the discharge potential of hydrogen.—B. N.

Nickel: Influence of superimposed alternating current on electro-deposition of —. S. A. Tucker and H. G. Loesch. *J. Ind. Eng. Chem.*, 1917, 9, 841–845.

IN the electro-deposition of nickel from a nickel-ammonium sulphate electrolyte, it is necessary to use impure anodes; anodes of pure nickel do not corrode properly but become passive. The authors made comparative tests on the effect of superimposing alternating current on direct current during the electrolysis, using anodes of roughened cast nickel and smooth cast nickel (Ni 91.87, Fe 6.10, C 1.63%), rolled nickel (containing small quantities of carbon and iron), and electrolytic nickel (Ni 99.8%). The effect of superimposing alternating current on the direct current was greatly to increase the anode corrosion with all varieties of anode, and this effect increased with the alternating current density. The increased corrosion at the anode raised the current efficiency at the cathode, especially with the rolled nickel anodes. Alternating current alone caused only slight corrosion at the anode.

Antimony plating baths; Tests of ——. F. C. Mathers and K. S. Means. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 3 pages.

DEPOSITION of antimony from numerous electrolytes was tried, such as the tartrate, chloride, oxalate, and fluoride, with the addition of glue, peptone, aloin, etc., as addition agents. Antimony fluoride is the most satisfactory electrolyte, when mixed with free hydrofluoric acid and a small amount of aloin, resorcinol, α -naphthol, β -naphthol, or salicylic acid.—B. N.

Antimony; Electro-deposition of ——— from fluoride baths containing addition agents. F. C. Mathers, K. S. Means, and B. F. Richard. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 9 pages.

ANTIMONY fluoride (5%) and free hydrofluoric acid (3%) give the best bath for deposition of antimony, with a suitable organic addition agent to prevent a crystalline structure. Of the numerous addition agents tried, the best results were obtained with aloin, α - and β -naphthol, and resorcinol. The addition agent should be added in quantity equal to 0.025 grm. per 100 c.c. of electrolyte every 12 hours during the electrolysis. The deposits are grey and finely crystalline, but too much of the addition agent makes the deposits darker and more glossy; a similar result is produced by adding very small amounts of clove oil (0.0012 c.c. per 100 c.c. of electrolyte). A crystalline rough structure indicates the need of more addition agent, but if dark or shiny in colour, or if it tends to crack, less addition agent must be used.—B. N.

Plating baths; Essential oils as addition agents in ——. F. C. Mathers and A. B. Leible. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 12 pages.

SQUARES of sheet metal, of uniform size, were shaken with aqueous solutions of the oils, and the amount adsorbed determined by difference by titrating the residual solutions. Oil was adsorbed by the metal, and the more readily the oil was adsorbed the greater was its effect as an addition agent in electro-deposition of the metal. The metals adsorb oil in decreasing order as follows: lead, antimony, copper, cadmium, zinc, iron, tin, silver. This is the order approximately of increasing difficulty in preventing rough crystalline deposits by the use of addition agents, and therefore indicates in a general way a relation between the effect of the oils as addition agents and their adsorption by the metals.—B. N.

Cerium chloride; Electrolysis of fused ——. M. de K. Thompson. Met. and Chem. Eng., 1917. 17, 213—215.

METALLIC cerium was obtained in a compact form by electrolysis, in a cast-iron crucible 6.8 cm. inside diameter and 7.5 cm. deep, the fused chloride prepared by dissolving the oxide in hydrochloric acid and dehydrating. The crucible formed the cathode, and the anode consisted of a graphite rod 2 cm. in diameter. A current of 90 amps. at 14 volts was passed, and with 882 amp.-hours, a nugget weighing 310 grms. was obtained with a current efficiency of 21%. By adjusting the current, voltage, and distance between the electrodes so as to give a temperature high enough to melt the cerium but not so high as to cause the formation of cerium carbide, a large amount of the deposited metal was caused to fuse together. The operation was conducted on a larger scale,

with current efficiencies of 20—30%, by melting the chloride in an iron electrolysis vessel of 22 cm. diameter so as to fill it to an initial depth of 2.5 cm. The anode, consisting of a graphite rod 5 cm. in diam., or a group of four of these rods, was preheated so as to prevent the salt from solidifying around it and acting as an insulator, and then inserted in the bath to a depth of 1.7 cm. The voltage between anode and cathode was adjusted to 10, giving a current of 250 to 300 amps. As the metal was deposited, the anode was raised, and chloride, preferably fused, was added. The vessel, after cooling, was broken open and the cerium remelted under sodium chloride and cast into bars in graphite moulds. A black substance, probably an intimate mixture of metallic cerium and cerium chloride, with which the metal is always surrounded, was recovered for another electrolysis by dissolving it in hydrochloric acid and evaporating to dryness.—J. N. P.

Metals; Effect of great hydrostatic pressure on the physical properties of ——. Z. Jeffries. Inst. of Metals, Sept., 1917. [Advance copy.] 5 pages.

CONTRARY to the results of Hanriot (Comptes rend., 1912, 155, 1502; this J., 1913, 606), the author finds that hydrostatic pressure up to 12,400 kilos. per sq. cm., applied at 25—40°C., has no effect on the hardness and tensile strength of aluminium or an alloy of the latter with 12% Cu. This discrepancy is possibly explicable on the ground that kerosene was used as the pressure-transmitting medium in the present work, whereas Hanriot employed vaseline, which freezes hard under pressure and thus renders hydrostatic conditions impossible. From the results obtained it is considered highly improbable that the hardness of metals can be increased without actual, permanent deformation, unless such increase in hardness is due to an allotropic change; even in the latter case, an apparent, permanent deformation would probably occur (owing to a change in volume), and the hardness of the metal would then be as likely to decrease as to increase.—W. E. F. P.

Hardness and hardening [of metals]. T. Turner. Inst. of Metals, Sept., 1917. [Advance copy.] 13 pages.

IN a general discussion of the subject, it is suggested that the hardness conferred on metals by cold-working is of a different kind from that produced by alloying; with a solid solution various methods of testing hardness should give uniform results, whereas the value obtained for the hardness of a cold-worked metal may vary with the method of testing. Cold-working also results, ultimately, in a decrease of density, and in view of these facts it is suggested that work-hardness may be due to the existence of amorphous films, or slip bands, held in tension within the metal, such bands or planes being akin to the surface films of liquids, but only limited in direction by the necessities of crystal symmetry.—W. E. F. P.

Low-temperature electro-thermal processes. Hirschfeld. See XI.

PATENTS.

Iron ore [containing aluminium, etc.]; Method of treating ——. F. A. Eustis, Milton, Mass. U.S. Pat. 1,237,765, Aug. 21, 1917. Date of appl., Jan. 12, 1917.

IRON ore containing aluminium and one or more of the metals nickel, cobalt, manganese, and

chromium is first treated to remove the whole or part of the aluminium. The residue is then subjected to a sulphating roast and, after being leached with water for the recovery of the remaining aluminium and other non-ferrous metals, is smelted for iron as usual.—W. E. F. P.

Copper: Electrolytic deposition of— from acid solutions. F. E. Studd, London. Eng. Pat. 108,688. (Appl. Nos. 6702, May 10, and 14,467, Oct. 11, 1916.)

Ores containing copper and iron are leached with the spent electrolyte recovered from a later stage of the process and containing sulphuric acid. During subsequent electrolysis, the electrolyte is kept saturated with sulphur dioxide which combines with the oxygen formed at the anode, and thus avoids the polarisation due to the accumulation of this gas on the electrode. The sulphur dioxide is introduced during the electrolysis, together with steam, through pipes disposed in the electrolysing vessel and provided with perforations at such angles that the gas and steam impinge on the surface of the anode and continuously circulate and agitate the electrolyte. The steam is regulated to maintain a temperature of 120—130° F. (49—53° C.). The most favourable current density is 13 amps. per sq. foot of anode surface. Ferric sulphate present in the solution is largely reduced by the sulphur dioxide to the ferrous salt, and its deleterious action in dissolving the cathodic copper is thus diminished. After the separation of the copper, use is made of the sulphuric acid which accumulates by dividing the electrolyte into two parts, one of which is applied for the leaching of a further quantity of ore, and the other is used for the preparation of sulphur dioxide by concentrating, and then heating with sulphur or carbon in a closed vessel. The sulphur dioxide evolved is led by pipes to a condenser for the separation of water vapour, then through sulphuric acid drying towers, and liquefied by compression.—J. N. P.

Electrodes for welding purposes. M. M. Irvine, Glasgow. Eng. Pat. 108,789, Nov. 21, 1916. (Appl. No. 16,661 of 1916.)

A WIRE or rod to be used as an electrode in electric welding processes is wound round to a thickness of 1—2 mm. with asbestos paper or pulp which is impregnated with a mixture of 5 parts of iron oxide and an aqueous solution of 5 parts of sodium carbonate and 90 parts of sodium silicate for every 100 parts of asbestos. On applying the mixture, the liquid is absorbed by the asbestos, while the iron oxide remains on the surface. The coated metal is then heated strongly to expel the water. During the process of welding, an arc is formed primarily by the electrode itself, and the external layer of iron oxide on the asbestos is reduced to metal. A conducting ring is thus formed round the crater of the arc, and the continuity of the arc is maintained after the interruption of the primary arc by the dropping of metal from the core.—J. N. P.

Solder or the like and the process of preparing the same. A. P. Bevan, Tavistock, Devon. Eng. Pat. 108,916, Sept. 11, 1916. (Appl. No. 12,806 of 1916.)

THE solder is produced by the incorporation of two metallic components, only one of which is fusible at the working temperature. Either or both components may consist of a metal, metal mixture, or alloy; as, for example, in the product obtained by incorporating finely divided and tinned particles of copper or copper alloy with ordinary soft solder.—W. E. F. P.

Annealing and like furnaces; Gas heated—. Dowson and Mason Gas Plant Co., Ltd., T. Wright, and E. W. Mawby, Manchester. Eng. Pat. 109,230, May 4, 1917. (Appl. No. 6351 of 1917.)

IN a gas-heated annealing or like furnace, gas from a horizontal supply chamber at the top passes downwards through orifices into a horizontal passage into which air for combustion is fed at one end. The mixed gases pass downwards through another series of orifices in the roof of the furnace. To produce a uniform distribution of gas and air among the orifices, these are made progressively smaller towards the inlet for the air supply by the insertion of suitable liners or otherwise, and each burner orifice is provided with a flange projecting upwards about half the height of the air passage. An upright baffle-plate, V-shaped in cross-section, equal in height to the air passage, may be provided in front of the orifice nearest the air inlet to ensure uniform distribution of the air.—W. E. F.

Smelting furnaces. H. A. Gill, London. From Vereinigte Hüttenwerke Burbach-Eich-Düdelingen Akt.-Ges. (Acidéries Réunies de Burbach-Eich-Düdelange, Soc. Anon.), Düdelingen, Luxemburg. Eng. Pat. 109,419, May 7, 1917. (Appl. No. 6498 of 1917.)

A TILTING furnace supported on rollers, for smelting ferro-manganese, spiegeliron, ferro-silicon, and like alloys, comprises two connected chambers, one at the front of the furnace for preliminary heating, and the other at the back for final melting. The charge is introduced at the front end, on to the floor of the preliminary chamber, and is heated nearly to melting point by means of liquid fuel supplied through a burner nozzle fixed horizontally at the rear end of the melting chamber. The charge is then pushed forward into the melting chamber, in the side of which a pouring spout is provided. In a modification, the floor of the preliminary heating chamber may be slightly hollowed.—W. E. F.

Hot-blast stove. H. A. Brassert and H. H. Jones, Chicago, Ill. U.S. Pat. 1,238,097, Aug. 28, 1917. Date of appl., Nov. 13, 1915.

THE air supply is admitted to the lower end of a vertical heating chamber, and passes upwards through vertical heating flues formed by courses of bricks of narrow section and small size, supported on arches. At the entrance to the flues, larger bricks are used to restrict the passages and distribute the blast uniformly among the flues.—W. E. F.

Tinplates and sheets and other like metal coated plates or sheets; Apparatus employed in the manufacture of—. H. B. Thomas, Englefield Green, Surrey, H. S. Thomas, Llandaff, and W. R. Davies, Whitchurch, Glamorgan. Eng. Pat. 109,302, Sept. 7, 1916, and Feb. 14, 1917. (Appl. Nos. 12,666 of 1916 and 2188 of 1917.)

A CONTINUOUS tinning machine of the kind described in Eng. Pat. 28,450 of 1913 (this J., 1915, 89) comprises a series of tables mounted on spring supports, side by side, at one end of the machine for the piles of sheets to be tinned. The sheets are fed forward singly by oscillating sucker devices on to rocking tables, which transfer them into a pickling bath through which they are moved by rotating wheels carrying projecting hooks. The plates are then carried by rollers under jets of water to the tinning bath, through which they pass at an

increased velocity, and thence through a "soaking pot" and "grease pot" to a branning machine. The plates then pass through two or more sets of cleaning or dusting rolls, each of which operates on the tinned surface at right angles to the preceding set. The plates are finally removed by an endless travelling conveyor moving at such a velocity that each series of plates is removed out of the path of the next following plates which are deposited on the conveyor. Two heating furnaces are used under the tin pot and soaking pot respectively. Additional flues are provided adjacent to the inlet side of the tin pot to counteract the cooling effect of the incoming cold plates on the flue, and at the side of the grease pot to heat the latter.—W. F. F.

Waste tins: Treatment of—[for recovering solder]. E. J. Lovegrove, London. Eng. Pat. 109,406, Mar. 28, 1917. (Appl. No. 4518 of 1917.) (See also Eng. Pat. 102,693; this J., 1917, 161.)

A HEATING chamber is arranged in a by-pass from the waste gas conduit or flue of any furnace other than a dust destructor. The inlet and exit for the hot gases are controlled by dampers. The tins are fed into the chamber without sorting, any adherent matter being burnt off and the solder melted in one operation. The fused solder is collected in a trough at the bottom of the chamber, the dampers are closed, and the tins then removed for pressing or baling.—W. F. F.

Metals; Process of extracting—from their ores. W. A. Schmidt, Assignor to Western Precipitation Co., Los Angeles, Cal. U.S. Pats. (A) 1,237,220 and (B) 1,237,221, Aug. 14, 1917. Date of appl., Feb. 18, 1916.

(A) THE ore is leached with a relatively weak solution of sodium chloride and ferric chloride, the resulting solution treated with metallic iron to precipitate the metal to be recovered, e.g., copper, regenerated by passing in an excess of chlorine produced by electrolysis of sodium chloride solution, and then used for the treatment of a further quantity of ore. (B) Ore containing a base metal compound in addition to the metal to be extracted is leached with a chlorine solution prepared by the action of chlorine on a solution of a chloride capable of oxidation to a higher chloride. The chloride in the leaching solution reacts with the base metal compound in the ore to form a chloride of the base metal, and the latter serves to retain in solution the metal extracted from the ore. From the resulting solution the metal is precipitated, and the solution then regenerated by the action of free chlorine, and used again. In applying the process to ore pulp, the water is first displaced by a solution of an alkaline-earth chloride, a chloride capable of forming a lower chloride is then dissolved in the solution to extract the metal from the ore, the metal is precipitated from the solution, and of the spent solution one portion is regenerated for use again and another portion used to displace water from a fresh supply of ore pulp.—J. N. P.

Ores; Process of concentrating—A. L. Pellegrin, Tucson, Assignor to H. Greenwell, Nogales, Ariz. U.S. Pat. 1,237,691, Aug. 21, 1917. Date of appl., Oct. 10, 1913. Renewed Feb. 2, 1917.

THE ore is dry crushed and separated into various predetermined sizes which, with the exception of the finest, are combined to form two or more mixtures. Each of the latter is then subjected to dry and wet concentration in succession, whilst the finest material is treated separately.—W. F. F. P.

Ore-concentrating method. A. Schwarz, Joplin, Mo., Assignor to Metals Recovery Co., New York. U.S. Pat. 1,237,961, Aug. 21, 1917. Date of appl., Jan. 17, 1917.

A GAS other than air is delivered through the perforated false bottom of one compartment of a closed vessel containing ore pulp and "modifying agents." The rising bubbles containing metal-liferous particles flow over a partition into the adjacent compartment, which is provided with a liquid seal, where the solid material is precipitated by a liquid spray. The liberated gas above the pulp mass is withdrawn and re-delivered to the bottom of the pulp compartment. Air is excluded from the system.—W. F. F.

Fine ores and like substances; Art of compressing—into blocks or briquettes. O. Kippe, Osnabrück, Germany. U.S. Pat. 1,238,022, Aug. 21, 1917. Date of appl., Jan. 12, 1917.

FINE ore is mixed with slaked lime and blast-furnace dust and subjected to the action of steam and pressure. A suitable briquette composition is fine ore concentrate 81%, blast-furnace dust (from hematite pig iron manufacture) 12%, calcium hydroxide 4%.—H. J. H.

[Zinc and barium] ores and metals; Process for the separation of—G. T. Wright and L. C. Hodson, Ames, Iowa, Assignors to Consolidated Chemical Products Co., Des Moines, Iowa. U.S. Pat. 1,238,242, Aug. 28, 1917. Date of appl., July 27, 1916.

ZINC ore containing a substantial quantity of barium sulphate is freed from gangue and oxidised till it contains zinc oxide and barium sulphate in equivalent proportions. The barium sulphate is then reduced to sulphide without reduction of the zinc oxide, and the two are caused to react, producing zinc sulphide and barium hydroxide. The latter is removed by leaching.—W. F. F.

[Ores and metallurgical products] carrying sulphur and metals; Process of treating substances—A. S. Dwight, New York. U.S. Pat. 1,238,279, Aug. 28, 1917. Date of appl., Mar. 5, 1914.

AN oxide of a metal having a strong affinity for sulphur is pulverised, mixed with carbonaceous material, and heated to reduce the oxide, and the sulphide ore or product to be treated is then added in the absence of air, so that sulphur is liberated and combines with the reduced metal forming a matte, which is subsequently used in ore smelting operations. Alternatively, the metallic oxide and the sulphide ore may be mixed and heated to redness, so that double decomposition takes place and a matte is produced.—W. F. F.

Blast-furnaces and the like; Hoists for charging—T. G. Wrightson, J. M. Ringquist, and Head, Wrightson, and Co., Ltd., Thornaby-on-Tees. Eng. Pat. 109,088, Aug. 29, 1916. (Appl. No. 12,232 of 1916.)

XI.—ELECTRO-CHEMISTRY.

Magnetite electrodes; Production and properties of —. M. de K. Thompson and T. C. Atchison. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 5 pages.

ANODES formed of magnetite may be rendered less brittle by incorporation of a small amount of copper oxide. Magnetite or a mixture of magnetite and copper oxide was fused in the interior of a graphite tube, 3.8 cm. inside, and 5.1 cm. outside diameter, the lower end of which was closed by a copper plate connected with one terminal of a 60-volt current supply, while the second terminal was connected to a carbon rod, 1.3 cm. diam. and 30 cm. long, held centrally in the tube. By raising the rod an arc of about 200 amps. was maintained in the tube. After the formation of the arc, magnetite or a mixture of magnetite and copper oxide was fed into the space between the rod and tube, and as the fusion proceeded, the rod was gradually raised and magnetite added until the fused product filled the graphite tube. Measurements of brittleness were made by supporting the two ends of an electrode, and finding the load necessary to cause fracture when applied at the centre. The breaking loads with electrodes of 3.8 cm. diam. and 25.4 cm. in length were found to range from 13 kilos. with pure magnetite to 117 kilos. with anodes containing 29% copper oxide. With anodes annealed by surrounding the graphite mould with asbestos so as to extend the interval of cooling after fusion over 8 hours, the toughness was more than doubled. The loss in weight through disintegration during use as anodes in the electrolysis of sulphuric acid solution was found to amount in the case of electrodes containing 5% copper oxide to 61.5 grms., and with anodes of pure magnetite to 103 grms. per sq. dm. per 1000 amp.-hrs. The difference in durability may be explained by the lower conductivity and consequent greater heating of the pure magnetite anodes.—J. N. P.

Low temperature electro-thermal processes [japaning, etc.] C. F. Hirschfeld. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 14 pp.

THE author uses the term "low temperature" as referring to temperatures below about 200°C.; and, as being fairly typical of many baking and drying processes in commercial use, the art of japaning is discussed at some length. By reason of the exact control of temperature conditions afforded, electrical heating has been found to give better results than other methods in japaning and in the baking of cores for foundry work. Suggestions are also made as to the employment of this method of heating in other industries, such as the baking of foods, etc.

—W. E. F. P.

Photo-chemical cell; A cuprous oxide —. T. W. Case. Amer. Electrochem. Soc., May, 1917. [Advance copy.] 4 pages.

A LARGE number of electrolytes have been found which deposit upon copper a photo-sensitive coating, probably due to the formation of a copper oxide or halide salt upon the electrode. A copper formate electrolyte, containing free formic acid, using highly polished copper electrodes, was studied closely. If one plate is illuminated and the other kept dark, a current is produced, the illuminated plate acting as the anode, and an E.M.F. of up to 0.11 volt is developed. The current finally drops to zero, but if the cell is rotated, illuminating the plate previously kept dark, the E.M.F. reappears. On continued rotation, the E.M.F. reaches a maximum value, but below a critical light intensity the cell gives very little response. The action of the cell is explained on the basis of the oxidation of cuprous to cupric oxide by the action of light.—B. N.

XII.—FATS; OILS; WAXES.

[Coconut oil:] *Combined Reichert-Polenske and modified Shrewsbury-Knapp process [for determination of —].* G. D. Elsdon. Analyst, 1917, 42, 295—298.

THE flask containing the residual fatty acids after the distillation of 110 c.c. in the Reichert-Polenske process, is disconnected from the condenser and placed in cold water. The cake of fatty acids is broken and the liquid strained through a fine wire sieve, the flask and fatty acids being washed with 50 c.c. of cold water. The fatty acids are drained on the sieve until practically free from water, then returned to the flask, and the flask and its contents are dried in a water-oven, air being blown into the flask at intervals; 100 c.c. of alcohol of sp. gr. 0.9200 (prepared from industrial methylated spirit) is then added, and the process is continued exactly as described previously (this J., 1917, 400). Mixtures of coconut oil with butter and with margarine examined by the above method yielded the following figures for the content of alcohol-soluble acids:

Percentage of coconut oil	0	10	20	30	40	50	60	70	80	90	100
With butter	12.7	14.5	16.5	20.6	24.0	30.4	—	44.4	53.3	76.5	89.8
With oleomargarine	8.9	10.6	13.7	16.9	20.8	25.4	31.8	41.8	53.4	73.2	89.8

—W. P. S.

Coconut oil and palm-kernel oil in mixtures; Differentiation of —. G. D. Elsdon. Analyst, 1917, 42, 298—299.

SINCE the Polenske values for coconut and palm-kernel oils are very different (about 17.0 and 11.0 respectively), whilst the Shrewsbury-Knapp values for the two oils are practically identical, it appears possible to distinguish between coconut oil and palm-kernel oil in mixtures of fats such as margarine by obtaining both the Polenske and Shrewsbury-Knapp values and the percentage of coconut oil from these data. Palm-kernel oil is probably present in those cases where the percentage of coconut oil calculated from the Polenske value is distinctly less than that calculated from the Shrewsbury-Knapp value. Knowing the sum of the quantities of coconut and palm-kernel oils present, it should be possible to calculate the relative amounts from the Polenske value. The results obtained, are, however, untrustworthy when coconut stearin is used in the fatty mixture, as this fat and palm-kernel oil have practically identical compositions.—W. P. S.

Oils and the like; Method and apparatus for extracting —. E. O. Barstow and T. Griswold, jun., Midland, Mich. U.S. Pat. 1,238,084, Aug. 28, 1917. Date of appl., Dec. 24, 1914.

A PORTION of the material to be extracted is treated

with a fluid solvent in an apparatus wherein the solvent used is removed, and the oil extracted material is then further treated with fresh solvent. A fresh portion of material is then treated with the solvent which contains the product of the previous extraction. Extraction is repeated a number of times, the solvent separated from the previous extraction being employed for treatment of material one step backward in the series or cycle of extractions, until it is finally used for the first treatment of the material, whilst the final extraction of the material is made with fresh solvent. The bulk of the mixture is maintained constant during treatment by automatically regulating the supply of fresh solvent according to the proportion of extract in the solvent separated.—A. DE W.

Catalytic reactions [hydrogenation of oils]; Process of effecting —. O. C. Hagemann, Yonkers, N.Y., and C. Baskerville, New York. U.S. Pat. 1,238,137, Aug. 28, 1917. Date of appl., Jan. 12, 1914.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Rubber; Influence of the age of the trees on the quality of the —. O. de Vries. Communication from the Central Rubber Station at Buitenzorg, No. 3. Archief voor Rubbercultuur in Ned. Indie, 1917, 1, No. 3.

UNDER similar conditions as regards the rubber content of the latex and the method of coagulation and preparation, the tensile strength of rubber from older trees is not appreciably greater than for that from young trees, and the type of the stress-strain curve is approximately the same, but the rate of vulcanisation decreases with age whilst the viscosity increases. The common belief that rubber from young plantations is of inferior quality is probably due in part to the poorer equipment of such plantations and the lower rubber content of the latex. In the case of the wild Brazilian rubber, the lower rate of vulcanisation due to the age of the trees is masked by the method of preparation, and plantation rubber prepared by an imitation of the Brazilian method is found to vulcanise more rapidly than crêpe prepared from the latex in the ordinary manner.—D. F. T.

[*Rubber*] *latex; Partial coagulation of —.* O. de Vries. Communication from the Central Rubber Station at Buitenzorg, No. 3. Archief voor Rubbercultuur in Ned. Indie, 1917, 1, No. 3.

ON coagulating latex with one part of acetic acid to 450–600 parts of rubber, it is possible to separate a "first clot," amounting to 15–25% of the total rubber, which forms a crêpe of strong yellow to dark brown colour, high viscosity, high rate of vulcanisation, and low tensile strength, whilst the second clot obtainable by subsequent further coagulation produces a very pale but otherwise fairly normal crêpe. If a greater proportion of acetic acid is used, a larger percentage of the total rubber is found in the first clot and the difference between the quality of the two fractions tends to disappear (compare Campbell. Bull. Ceylon, No. 27).—D. F. T.

Rubber content of latex; Influence of — on the quality of the rubber. O. de Vries. Communication from the Central Rubber Station at Buitenzorg, No. 2. Archief voor Rubbercultuur in Ned. Indie, 1917, 1, No. 1.

THE tensile strength and "type" of rubber are not affected appreciably by the concentration of the latex from which it is coagulated, but the viscosity is very slightly diminished and the rate of vulcanisation appreciably reduced by dilution of the latex. In the preparation of smoked sheet, a standard concentration is in general use, 15% being the usual value in Java, and a standard degree of dilution is also desirable for the production of crêpe. Such standardisation not only ensures a more uniform product but also permits an accurate and economical adjustment of the amount of acetic acid to be used.—D. F. T.

Rubber solutions; Viscosity of —. A. van Rossem. Communications of the Netherland Government Institute for Advising the Rubber Trade and the Rubber Industry, 1917, Part III.

FOR the determination of the viscosity of rubber solutions the Ostwald viscometer as adapted by Fol (this J., 1913, 437) is recommended. Although Gorter's claim (1915. Dep. Landb., Nijverh.

Handel Ned.-Ind.) that calculation of the relative viscosity of rubber solutions in benzene from the ratio of the times of flow of the solution and of the solvent gives a result too low by 12%, is conceded, his alternative method of arriving at the value of a "viscosity index" representing the logarithm of the relative viscosity at a concentration of 1% is shown to be incorrect. By making use of numerous earlier results a set of standard relative viscosity curves has been constructed, based on rubbers of the following relative viscosities in 1% solution: 19.5, 29.5, 39.5, 49.5, 59.5, 69.5, and 79.5, the respective corresponding "viscosity numbers" (Fol, *loc. cit.*) approximating to 40, 50, 60, 70, 80, 90, 100; these curves do not intersect and, by making one measurement of relative viscosity with a solution of known concentration, the position of the curve for a new rubber can at once be determined and its viscosity number estimated directly from the curve. The viscosity of a 1% solution of rubber is unaffected by mere shaking or repeated passage through the viscometer, but on exposure to light it undergoes a noticeable reduction; the presence of moisture in the benzene causes a slight lowering in the viscosity, whilst acids induce a very marked diminution, so that solvents such as chloroform and trichloroethylene are not suitable for viscosity work. If rubber is at first incompletely dissolved in benzene, the residue gives a more viscous solution than the first extract, this result being possibly due to the influence of the resins in the first extract and to the higher viscosity of the nitrogen-enriched rubber in the second solution; the separation of the rubber into fractions of different degrees of polymerisation, by such processes of partial solution, is considered to be unlikely. Comparative experiments with benzene, toluene, and carbon tetrachloride as solvents demonstrated that at 1% concentration the toluene solution is slightly less fluid than the benzene solution, and the carbon tetrachloride solution decidedly less fluid than either, the ratio of the relative viscosities in any two of the solvents being higher, the greater the viscosity of the rubber. Removal of the natural resins from rubber by extraction with acetone decreases the viscosity on account of the effect of heat; addition of the resin to the extracted rubber reduces the viscosity still further. The introduction of compounding ingredients, such as sulphur, litharge, and magnesium oxide, causes no other change in the viscosity of the solution after it has been allowed to settle, than is to be expected from the mere additional presence of the dissolved sulphur. The real significance of viscosity tests is indicated by the fact that a uniform sheet of unsmoked Hevea rubber after heating at 100° or 130° C. in carbon dioxide exhibits a reduction in "viscosity number," in tensile strength, and in percentage elongation at break; mastication between rolls causes a still more marked decrease in all three characteristics. A high "viscosity number" in a raw rubber is generally a concomitant of rapidity of vulcanisation. After being swollen with benzene and then allowed to dry again, unvulcanised smoked Hevea sheet is found to possess increased tensile strength and especially increased elongation at break, but the resistance to stretch is diminished. It is believed that a parallelism exists between the "degree of swelling" of raw rubber and the "viscosity number."—D. F. T.

Rubber; Percentage of moisture in raw —. A. van Rossem. Communications of the Netherland Government Institute for Advising the Rubber Trade and the Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies; 1917, Part II., 40–40.

THE method of determination is to dry 3–5 grms.

of finely cut rubber in a hot-water oven until the weight is constant; the time required is at least 2 hours, and with very moist rubbers may reach 8 hours. Many analyses of first latex rubbers show that sheets have a somewhat higher moisture content than crêpes, whilst wild Para rubber generally contains a lower proportion of moisture than such rubbers as those obtained by the Kerbosch, Schadt, Byrne, or da Costa process. Apart from the probable effect of hygroscopic constituents in the rubber, originating from the latex, it is shown that the hygrometric state and temperature of the atmosphere also influence the absorption and retention of moisture. Rubber exposed to saturated air at 30° C. takes up a greater quantity of water than rubber in saturated air at 16° C.; but when the moisture in the air is below 85% of the maximum quantity, the rate of absorption of water is greatly reduced.—D. F. T.

Rubber; The so-called insoluble part of raw —. A. van Rossem and Dekker. Communications of the Netherland Government Institute for Advising the Rubber Trade and Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies. 1917, II., 56—68.

For the determination of the non-caoutchouc insoluble constituents of rubber, 2 grms. is heated with 40 c.c. of petroleum (b. pt. 230°—260° C.) for 2—3 hours, after which time a clear solution containing a little flocculent matter is obtained, the insoluble matter then being separated by centrifuging and washing. Only 55—65% of the nitrogen of the rubber is found in the residue; the total weight of the organic residue amounts to 2—3%, containing 8½—11% of protein if the latter is assumed to have a content of 16% of nitrogen. These figures were obtained for Hevea plantation rubber and hard fine Para, and indicate that the nitrogen of raw rubber is not wholly present in the form of protein matter. The earlier view of the Institute that the caoutchouc portion of raw rubber more difficultly soluble in the ordinary rubber solvents represented a more highly polymerised form of rubber is now withdrawn. When rubber, especially Hevea plantation rubber, is heated at 110°—130° C., in carbon dioxide for 0.5—3 hours, there is a marked increase in the proportion of insoluble matter present; this effect is not observed in rubber which has been masticated. The increase in the insoluble fraction is accompanied by a slight increase in the percentage of protein in the fraction, but must be attributed mainly to the decreased solubility of the caoutchouc. In 1888 (Trans. Chem. Soc., 1888, 769), Gladstone and Hibbert observed an increase in the insoluble substances of rubber when the latex was heated during coagulation. (See also Terry, this J., 1899, 173.)—D. F. T.

Rubber; Water extract of raw —. A. van Rossem. Communications of the Netherland Government Institute for Advising the Rubber Trade and Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies. 1917, II., 66—68.

The method of extraction is to treat 3 grms. of finely cut rubber for 6 hours with 100 c.c. of distilled water on the water-bath and then, after filtering, to extract the residual rubber for a second time with 50 c.c. of water; the combined filtrate is evaporated on a water-bath and dried for an hour at 100° C. The average extract for Hevea plantation rubber was about 0.5%, the maximum being near 1%, whilst the average for wild Para was 0.4 to 0.5%. Rubbers obtained by evaporation of latex naturally gave higher figures. The extract contains about two-thirds of the mineral

matter of the rubber and also a portion of the nitrogen, this result indicating the presence of other nitrogenous substances in addition to protein in rubber; other unidentified substances were also present, probably including inositol or derivatives of this substance.—D. F. T.

Rubber; Degree of acidity of raw —. A. van Rossem. Communications of the Netherland Government Institute for Advising the Rubber Trade and Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies. 1917, II., 68.

Five grams of the finely cut rubber is left standing for 24 hours with 100 c.c. of cold, recently boiled, distilled water; an aliquot portion is then titrated with N/100 sodium hydroxide solution and phenolphthalein and the "degree of acidity" represented by the number of c.c. of N/100 alkali per gram of rubber. For first latex Hevea sheets the average result was 0.5, the highest being 1.3 and the lowest 0.1; for crêpes the average was 0.1, the highest and lowest being 0.4 and 0.1 respectively. Hard Fine Para gave figures ranging from 0.4 to 0.5, whilst rubbers obtained by evaporation of latex gave higher results.—D. F. T.

Rubber; Indirect method to determine the percentage of —. A. van Rossem. Communications of the Netherland Government Institute for Advising the Rubber Trade and Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies. 1917, II., 69—70.

It is suggested that the combined total of the moisture, water-extract, and acetone extract of the original rubber and of the ash and protein (factor 6.25) on the extracted and dried sample be corrected for the part (generally 20%) of the acetone extract which is soluble in water, and then be subtracted from 100. If rubbers obtained by evaporation of latex are excluded, it is sufficient to subtract from 100 the total percentages of moisture, resin, ash, and protein (factor 6.25); the totalling of the moisture, resin content, and petroleum-insoluble fraction (see above) is a possible alternative, but gives slightly high results owing to the fact that the petroleum-insoluble matter includes only part of the protein.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Tanbarks; Philippine —. V. Q. Gana. *Philippine J. Sci.*, 1916, 11, A, 261—265.

ONLY mangrove and camanchili (*Pithecolobium dulce*, Benthams) barks are used at present in the Philippine Islands for tanning purposes, and as the use of either bark is attended with disadvantages, other barks have been investigated with a view to their utilisation. Of those tested only two, the Philippine pine (*Pinus insularis*) and palo maria (*Calophyllum inophyllum*) are both satisfactory in quality and sufficiently plentiful. Neither is rich in tannin, the former containing 3.8% and the latter 11.9% tannin, calculated on the dry material. Other barks are richer in tannin and yield leather of good quality, but cannot be collected economically.—F. C. T.

PATENT.

Glue and allied substances; Machine for cooling —. K. Upton, Marblehead, Mass. U.S. Pat. 1,237,587, Aug. 21, 1917. Date of appl. Dec. 20, 1916.

THE glue is pumped from a primary container into a secondary container at a higher level in which it is maintained at any desired constant level, and is fed from this secondary container on to a rotary cooling wheel.—F. C. T.

XVI.—SOILS; FERTILISERS.

Coal gas; Action of — on plants. II. Action on green plants. C. Wehmer. *Ber. Deut. bot. Ges.*, 1917, 35, 318—332. *J. Chem. Soc.*, 1917, 112, i., 531—532. (See also this J., 1917, 1021.)

It is usually affirmed that coal gas is poisonous to green plants even when the atmosphere contains only minute quantities, but cress is remarkably resistant to its influence. The seedlings will grow unchecked in an atmosphere containing as much as 30% of gas, but they die in a short time if exposed to undiluted gas. The seeds themselves are not killed by coal gas, but only prevented from germination. The ill-effects of undiluted coal gas are not entirely due to the lack of oxygen, for cress will keep fresh and green in pure hydrogen for a much longer time than in coal gas. Experiments designed to elucidate the nature of the particularly poisonous constituent of coal gas gave only negative results. Carbon monoxide, ethylene, and acetylene are not dangerous, even in concentrations much higher than those in which they commonly occur in coal gas. Benzene vapour, carbon bisulphide, and hydrogen sulphide are very toxic, but not in the concentration met with in coal gas. The really toxic constituent is probably among the minor impurities.

Fertilisers; Manufacture of compound —. C. Deguide, Le Portel, France. Eng. Pat. 109,079, Aug. 28, 1916. (Appl. No. 12,135 of 1916.) SEE Fr. Pat. 480,569 of 1915; this J., 1917, 152.

XVII.—SUGARS; STARCHES; GUMS.

Sugar refining; Use of vegetable decolorising carbon as compared with animal charcoal (bone-black) in —. M. Weinrich. *Int. Sugar J.*, 1917, 19, 406—407.

As a result of experiments with various kinds of

vegetable decolorising carbons in comparison with animal charcoal, made partly in collaboration with the late B. E. R. Newlands, it is stated that vegetable carbons are inferior to bone-black for use on the large scale. Animal charcoal removes as much colour as an equal volume of vegetable carbon, and in addition removes organic and mineral impurities not affected by the vegetable carbon. The specific gravity of the best kind of vegetable carbon is only about 10% of that of animal charcoal, and after each revivification, which is troublesome and expensive, the vegetable carbon is found to have shrunk more or less and to have a diminished absorptive power. The claims put forward in favour of the vegetable carbon, "Norit," are strongly criticised, and it is asserted that the process for the manufacture of another vegetable carbon, "Carbrox," was anticipated by the author's U.S. Pat. 155,875 of July 7, 1891. As a cheap filtering agent, comminuted crude bagasse, obtained by passing the bulk of the bagasse, before it goes to the furnaces, over a sieve agitated by a crank shaft, is recommended. This is added to the defecated juice which is then passed through filter-presses. Full cakes can be obtained, which are easily washed, and the filtered juice is perfectly clear.

Utilisation of horse-chestnuts. Goris. See XIXA.

XVIII.—FERMENTATION INDUSTRIES.

Beer; Oil in adjuncts and its effect on quality of —. P. Dreesbach. *Amer. Brewers' Review*, 1917, 233—235.

THE raw cereal adjuncts commonly used in brewing contain considerable amounts of oil, e.g., maize meal 1—1.5%, grits 0.8—1%, flakes 0.6—0.7%, and rice 0.7—0.8%. This oil, even in the fresh state, has a harsh flavour and cannot improve the flavour of beers. Its slow decomposition causes the adjuncts to become musty on storage. There is evidence that during the "cooking" of the adjuncts to gelatinise the starch, some of the oil is saponified, with the result that small quantities of the higher fatty acids pass into the wort; a certain quantity of the oil also appears to become emulsified by extractive matters present and thus passes into the wort, but is again liberated when the extractive matters undergo fermentation, and then affects unfavourably the flavour and head-retaining power of the beer. The author recommends the use of oil-free adjuncts, including besides brewing sugars, certain "refined" products obtained from maize by the wet milling process. These products contain only about 0.05% of oil and are practically free from protein. They do not become musty on storage and require only a very short "cooking" (refined grits) or none at all (refined flakes). They affect the flavour of beer much less than adjuncts containing oil, and they can therefore be used in larger amounts than the latter.—J. H. L.

Enzymes [urcase]; Formation of —. III. M. Jacoby. *Biochem. Zeits.*, 1917, 81, 332—341. *J. Chem. Soc.*, 1917, 112, i., 528—529. (See also this J., 1917, 663, 901.)

IN continuation of previous work, it is shown that the addition of edestin, but not of caseinogen, to Uschinski's medium promotes the formation of the urase. The addition of glycine, alanine, tyrosine, or valine was without effect. It was also found that culture on medium from certain bouillon tablets promotes enzyme formation, and that the further addition of amino-acids accelerates

this formation still more. The bouillon tablets also promote urease formation when added to Uchinski's medium. From the above-mentioned results, the conclusion is drawn that Uchinski's medium is wanting in amino-acids and some other substance which is contained in the bouillons and in the hydrolysis products of edestin. Further experiments showed that synthetic leucine had no effect on urease formation when added to Uchinski's medium, whereas pure *l*-leucine, and *d*- and *l*-isoleucine (obtained from F. Ehrlich), promoted the formation of the enzyme. It has therefore been found possible to obtain the enzyme when bacteria are grown on media containing only simple chemical substances.

Aldehydes in wines. J. Laborde. Ann. Inst. Pasteur, 1917, 31, 215—252. J. Chem. Soc., 1917, 112, i., 532.

A COMPREHENSIVE study of the catalytic and physiological agents causing aldehyde formation in wines. These agents exercise their influence principally on the young wines during their storage in barrels, which helps more or less the contact of the wine with atmospheric oxygen. The three principal catalytic agents promoting aldehyde formation are: (1) the tannin substances, more or less combined with potassium hydroxide; (2) *oxo*xydase; (3) the oxydase of *Botrytis cinerea*. Pasteurisation of normal wines, as well as the addition of sulphurous acid, checks aldehyde formation without completely preventing it. Pasteurisation has a similar effect on "cassable" wines, but in this case sulphurous acid favours aldehyde formation, whilst preventing the "casse." There are equally important opposing influences which may lead to the complete disappearance of aldehyde from the wine if it is stored in the absence of air, and on this account but small amounts of aldehydes are to be found in red wines stored normally. In the case of "cassable" wines, the aldehyde plays no part, since it is only formed after marked oxidation of the tannin substances. Aldehyde formation opposed by aldehyde destruction has only a passing influence, although always unfavourable, on the bouquet of red wines in casks.

Of the micro-organisms which live in wine, only the facultative aerobic organisms (different yeasts) and the strictly aerobic organisms (mycoderma) produce aldehyde, although certain anaerobic ferments apparently yield acetaldehyde by attacking the glycerol of the wine. The yeasts and anaerobic microbes secrete reductases in the wine, which can contribute to the complete removal of aldehydes in wine kept out of contact with air, unless the aldehydes are combined with sulphurous acid.

XIXA.—FOODS.

Milk; Analysis of —. C. Porcher and R. Dage. Ann. Chim. Analyt., 1917, 22, 170—179.

THE author criticises the method proposed by Ackermann (this J., 1917, 1025), pointing out that the refraction of milk serum is not always a measure of the amount of lactose present, soluble proteins interfering. As a result of numerous experiments with various milks, it is concluded that the value proposed by Ackermann (non-fatty solids less lactose) is of little use in judging the quality of the milk.—W. P. S.

Horse-chestnuts; Utilisation of —. A. Goris. Comptes rend., 1917, 165, 345—348. (See also this J., Auld, 1913, 173; Rousset, 1913, 243.)

THE present economic conditions render the

possibility of the industrial utilisation of horse-chestnuts a matter of importance. The brown integument contains aesculin and a tannin and is of no industrial value; it is fairly easily detached from the kernel in the fresh state, but adheres firmly after drying. The kernel (cotyledons) contains 2—3% of fat, 6—7% of nitrogenous matter, and 20—30% of starch, besides bitter substances of the saponin group and colouring matters, but contrary to the statements of some authors it contains neither aesculin nor tannin. The oil is of no interest industrially, and as it forms an obstinate emulsion with the saponins, extraction is only practicable after these have been largely destroyed or transformed by desiccation or fermentation. Owing to the medicinal properties of the saponins, and their bitter flavour, pulp or flour obtained from the kernel cannot be used as foodstuff without a treatment to remove them. For this purpose the author recommends washing with dilute acid, e.g., a 0.1% solution of hydrochloric acid, by which treatment yields of 20—25% of white, odourless and tasteless flour have been obtained in the laboratory. The starch grains are irregular, some being small, rounded or ovoid, others bulky, pear-shaped or ellipsoidal, with a well-marked linear or stellate hilum in the largest part. The striæ are not very distinct. The starch might serve for the production of alcohol or even as food. Factories for the production of starch from horse-chestnuts were formerly installed in the neighbourhood of Paris, but they were not remunerative, owing to the cost of labour and transport.—J. H. L.

XIXB.—WATER PURIFICATION; SANITATION.

Silver nucleinate, a substitute for copper sulphate in combating vine mildew. A. von Degen. Allg. Wein-Zeit., Vienna, 1917, 34, 25—28. Bull. Agric. Intell., 1917, 8, 941—942.

OWING to the scarcity of copper sulphate in Austria

tests were made with a preparation of silver nucleinate, consisting of greenish black plates with a metallic lustre, completely soluble in water forming a brownish opaque solution stable in the dark. Vines subject to a moderately severe attack by *Plasmopara viticola* were sprayed with a 0.5% solution five times between May and August, with satisfactory results, the yield of grapes being excellent and the leaves formed in spring remaining on the plants till the end of autumn, whilst in untreated plants the leaves had been destroyed by June. The solution adhered well to the leaves and left small spots of precipitated metallic silver, below which the tissue was partly destroyed, though without interfering with the general functioning of the leaves. The solid nucleinate is sold at 45 Crowns (equivalent to 37s. 6d. before the war) per kilo., and 30–50% solutions are relatively cheaper; in certain cases it would prove more economical than copper sulphate at present prices.—J. H. L.

Refuse burning installations. B. E. D. Kilburn, London. From Sulzer Frères Soc. Anon., Winterthur, Switzerland. Eng. Pat. 109,179, Dec. 13, 1916. (Appl. No. 17,901 of 1916.)

THE refuse is delivered into vertical water-jacketed shaft furnaces where it is burnt by means of an air blast. The charging hoppers and furnace covers are made to move alternately over the furnace openings. The gases pass out at the top into a combustion chamber having transverse baffles projecting from the top and bottom alternately, and thence to a water-tube steam generator. The clinker in the furnace is cut by a hydraulically operated knife, and drops into a truck which conveys it along a passage below the combustion chamber to a quenching tank. Flue dust is discharged into the same passage through openings in the bottom of the compartments in the combustion chamber. To avoid escape of gas and dust during removal of the clinker, the lower passage is connected with a dust exhauster operated by an air ejector which is fed from the blast from the furnace blower.—W. F. F.

Water; Treatment of—for softening, purifying, and like purposes. H. J. Magrath, London. U.S. Pat. 1,239,202, Sept. 4, 1917. Date of appl., Nov. 22, 1916.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Sensitiveness of the usual method of extracting—from their aqueous solutions. L. Launoy. Comptes rend., 1917, 165, 360–362.

THE alkaloids used in the experiments were aconitine, atropine, brucine, cocaine, colchicine, eserine, pilocarpine, strychnine, veratrine, and conicine. Two hundred c.c. of solution was rendered distinctly alkaline with sodium carbonate and extracted three times with chloroform (10 c.c., 10 c.c., and 5 c.c.); the chloroform extract was evaporated, the residue dissolved in 1 c.c. of dilute sulphuric acid (1:10), and the solution tested for the presence of various alkaloids. In this way it was found that distinct reactions could be obtained when the original solution contained as little as 1 part of alkaloid per 2 million parts of solution.

—W. P. S.

Datura alba. H. C. Brill. Philippino J. Sci., 1916, 11, A, 257–260.

IN connection with a survey of the medicinal plants of the Philippine Islands, investigations have been made regarding the alkaloid content of the various parts, fresh and dried, of the plant *Datura alba*. It was found that the fresh parts usually contain more than the dried parts and that the various parts range in the following order of alkaloid content: Mature seeds, flowers, stems, immature fruit, and leaves, the first having the highest. Prolonged drying and heating at high temperatures cause a loss of the alkaloid. The alkaloid is more readily extracted by alcohol from an acid than from a neutral or alkaline suspension. The following method is suggested for extraction on the commercial scale:—The raw material is ground finely, treated with hot acidified water, and this extract treated with fullers' earth which removes the alkaloid. The earth is then treated with alkali and extracted with alcohol.—L. A. C.

Essential oil production in British East Africa. Perfum. and Essent. Oil Rec., Sept., 1917, 263–261.

SAMPLES of oil distilled from plants grown at Lamoru, British East Africa, gave very promising results. The district is at an altitude of about 7000 ft., has two rainy seasons, and is probably entirely suitable for the growth of many essential oil-yielding plants. Oil of spike lavender had the following characteristics:—Sp. gr., 0.894; opt. rotation, $-10^{\circ} 30'$; esters, 3.0%; alcohols, 44.1%. The oil is very fragrant and pungent and has a very high content of alcohols. Rosemary oil had the following characteristics:—Sp. gr., 0.908; opt. rotation, $+1^{\circ}$; esters, 4.2%; alcohols, 15.0%. The oil was distilled from the spikes only and shows a high ester content. A sample of geranium oil was somewhat disappointing, not having a particularly pleasing odour, but was probably distilled from the leaves and stems of very old plants. A sample of lemon thyme oil contained 18% of citral and 6% of phenols; this oil, however, is probably of little market value.—L. A. C.

Citric acid and tartaric acid [; Detection of—]. T. C. N. Broeksmijt. Pharm. Weekblad, 1917, 54, 686–687. J. Chem. Soc., 1917, 112, ii, 429.

CITRIC and malic acids are oxidised by a solution of potassium permanganate in acetic acid to acetone, which can be identified by the iodoform test. The two acids can be distinguished by the fact that barium citrate can be crystallised. The acetone reaction is applicable to the detection of citric acid in tartaric acid and in lemonade syrup. The presence of tartaric acid in citric acid and in lemonade syrup can be proved by the formation of potassium bitartrate.

XXIII.—ANALYSIS.

Potassium and sodium; Determination of — [in the ash of vegetable substances]. H. Pellet. Ann. Chim. Analyt., 1917, 22, 146—152, 179—185.

THE substance is incinerated at a low heat, the carbonised mass extracted with water, the insoluble portion ignited separately, and the ash added to the solution, which is then evaporated and the residue heated gently. To determine potassium and sodium, 5 grms. of the residue is extracted many times with boiling water, the extracts are filtered, and the solution made up to 500 c.c.; 200 c.c. of this solution is treated with an excess of saturated barium hydroxide solution, phenolphthalein is added, and carbon dioxide is passed into the mixture until the pink coloration disappears. After the addition of a few c.c. of saturated ammonium carbonate solution, the mixture is heated, filtered, the filtrate evaporated, and the residue ignited. This residue is extracted with water, the solution is filtered, the filtrate evaporated with the addition of hydrochloric acid, and the residue of chlorides thus obtained is ignited at a low temperature and weighed. The excess of barium hydroxide may be removed by the addition of ammonium carbonate solution, instead of with carbon dioxide. The potassium in the mixed chlorides is determined by precipitation with platinum chloride. The filtrate and washings (a mixture of alcohol and ether is used) are evaporated to remove alcohol and ether, so that a solution is obtained containing only sodium chloride, platinum chloride, and possibly a small quantity of reduced platinum. The solution is boiled with the addition of an excess of ammonium formate, the reduced platinum separated by filtration, the filtrate evaporated to dryness, and the residue ignited to expel ammonium salts. The ignited residue is treated with a few drops of hydrochloric acid, evaporated, and the residue of sodium chloride thus obtained is weighed after gentle ignition. The quantity of sodium found should agree with that calculated from the difference between the amount of potassium chloride and that of the total chlorides. If desired, the quantity of potassium found may be checked by reducing the potassium chloroplatinate with sodium formate and weighing the platinum black.—W. P. S.

Gallium; Qualitative separation and detection of —, P. E. Browning and L. E. Porter. Amer. J. Sci., 1917, 44, 221—224.

IN the ordinary course of analysis, gallium appears in the group containing aluminium, beryllium, chromium, and vanadium, from which group the last two elements may be removed by oxidation to the acidic condition and treatment of the solution with ammonia. Potassium ferrocyanide may be used for the separation of gallium from the remaining elements of the group, the separation from aluminium being the more important since beryllium is seldom present in products containing gallium. The test depends on the insolubility of

gallium ferrocyanide in hydrochloric acid; in a series of trials, each made in a volume of 5—10 c.c., of which from one quarter to one third was strong hydrochloric acid, 0.001 gm. Ga was precipitated at once by the addition of potassium ferrocyanide, whereas 0.1 gm. Al or Be gave no precipitate. Under similar conditions a precipitate was obtained with 0.0001 gm. Ga after standing for an hour. The test is vitiated by the presence of traces of zinc, but the latter may be removed by addition of hydrogen sulphide to the sodium hydroxide solution of the metals. The zinc sulphide is filtered off and the filtrate acidified, boiled to remove hydrogen sulphide, and then made alkaline with sodium hydroxide and treated with hydrogen peroxide to oxidise the free sulphur. The liquid is then boiled to decompose the excess of hydrogen peroxide, acidified with hydrochloric acid, and treated with potassium ferrocyanide. By this means it was found possible to detect 0.0002 gm. Ga in the presence of 0.05 gm. Zn. The most satisfactory method of decomposing gallium ferrocyanide and recovering the metal as hydroxide is to fuse the compound with ammonium nitrate and treat the residue with sodium hydroxide; a solution of gallium is thus obtained from which the hydroxide is precipitated on boiling with excess of ammonium chloride. The ether process for the separation of aluminium and iron chlorides is also applicable to the separation of aluminium from gallium, the latter being obtained as chloride in ethereal solution; in this way, 0.0005 gm. Ga was detected in the presence of 0.1 gm. Al, the ethereal solution being evaporated to dryness and the residue dissolved in hydrochloric acid before the addition of potassium ferrocyanide. Subsequent experiments showed the precipitation of gallium ferrocyanide to be partly or wholly prevented by the presence of nitrates or nitric acid, but that these could be successfully removed by evaporation with hydrochloric acid.—W. Official Notice.

MINISTRY OF MUNITIONS ORDER. OCTOBER 23RD, 1917.

Tar oils.

The Minister of Munitions, in exercise of the powers conferred upon him by the Defence of the Realm Regulations and all other powers thereunto enabling him, gives notice and orders as follows:

(1) He hereby takes possession as from the 1st November, 1917, until further notice, of all tar oils then or thereafter situate in the United Kingdom produced or derived from gas coal tar or coke oven tar of a specific gravity of 1000 or exceeding 1000, or produced or derived from water gas tar, producer tar or Mond gas tar of any specific gravity.

(2) If any person having control of any tar oil to which this Order applies without the consent of the Minister of Munitions sells, removes, or secretes it or deals with it in any way contrary to any conditions imposed in any licences that be granted in respect thereof, he will be guilty of an offence against the Defence of the Realm Regulations.

(3) No person shall on or after the 1st November, 1917, until further notice purchase or take delivery of any tar oil situate in the United Kingdom except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions, or offer to sell, sell, supply, or deliver any such tar oil to any person other than the holder of such a licence and in accordance with the terms thereof. Provided that no such licence shall be required:

(a) By any person for the purchase and delivery of tar oil in quantities not exceeding an aggregate of 5 gallons during any one calendar month.

(b) By any person, after the first application by him for and pending the granting or refusal of a licence, for the delivery to him under a contract in writing existing at the date hereof of tar oil for the purpose of benzol washing or the manufacture of disinfectants, antiseptic drugs, lamp or vegetable black, or fuel, to an amount not exceeding during any one calendar month the amount of the average monthly deliveries under such contract during the three calendar months immediately preceding the date hereof.

(4) No purchase or sale of tar oil situated in the United Kingdom, or offer to purchase or sell any such tar oil whether such purchase, sale or offer is or is not under any licence issued under the authority of the Minister of Munitions, shall, in the case of any class of tar oil specified in the Schedule hereto, be until further notice at a price exceeding the price fixed for the same in the said schedule, provided that this clause shall not apply to any deliveries under and in pursuance of a contract in writing entered into prior to the 13th July, 1917.

(5) No person, whether he is or is not the actual producer of such tar oil, shall on and after the 1st November, 1917, until further notice use any tar oil exceeding in quantity 5 gallons in any one calendar month for the purpose of or in connection with any manufacture or work except under and in accordance with the terms of a licence issued under the authority of the Minister of Munitions.

(6) All persons producing or holding stocks of tar oils shall furnish to the Controller of Explosives Supply, Storey's Gate, Westminster, S.W.1, as and when required by him such returns of tar oils at any time manufactured, purchased, sold, supplied, delivered or used by them at such times and in such form as the said Controller of Explosives Supply shall from time to time direct.

(7) All persons heretofore required by the Minister of Munitions to furnish returns relating to tar oil shall until further notice continue to furnish returns in accordance with such previous requirements.

(8) For the purpose of this Order the expression "tar oil" shall mean creosote oil, green oil, sharp oil, anthracene oil, and other oils produced from or containing an admixture of oil produced from the distillation of coal tar, coke oven tar, producer tar, water gas tar and Mond gas tar or any of them.

(9) The Order of the Minister of Munitions dated the 13th July, 1917, relating to creosote and other oils produced from the distillation of coal tar is hereby cancelled as from the 1st November, 1917, but such cancellation shall not affect the previous operation of that Order prior to such last mentioned date or the validity of any action taken under it, or the liability to any penalty or punishment in respect of any contravention or failure to comply with the same respectively prior to its cancellation, or any proceeding or remedy in respect of such penalty or punishment.

(10) All applications for licences under this Order shall be made to the Controller, Mineral Oil Production Department, Ministry of Munitions, 8, Northumberland Avenue, W.C.2.

The Schedule. Maximum prices.

(1) Oil for benzol washing complying with the following specification:—

Sp. gr. at 60° F. not less than 1020. Shall deposit no naphthalene crystals at 45° F. On distillation in retort with thermometer in liquid shall give no distillate below 200° C., not less than 5% at 230°, and not less than 90% at 300°—100s. per ton.

For each degree F. by which the crystallising point is above 45° F. 1s. per ton shall be deducted from the price, and for each 1% by which the volume of distillate at 300° falls below 90% 6d. per ton shall be deducted from the price.

(2) Oil for fuel purposes.

(a) For use in Diesel engines complying with the following specification:—

Sp. gr. not exceeding 1.100 calorific value, not less than 15,800 B.T.U.'s; fluid at 600° F., maximum content of water 2%; coke 5%; ash 0.10%—87s. 6d. per ton.

(b) For other engines and furnaces generally:—

(1) Admiralty Specification oil, 72s. per ton.

(2) 75% creosote oil and 25% pitch, 61s. 6d. per ton.

(3) 66 2/3rds % oil and 33 1/3rd %, pitch 58s. per ton.

(4) 50% creosote oil and 50% pitch, 51s. per ton.

(5) 40% and less creosote oil and 60% and upwards pitch, 47s. per ton.

A commission not exceeding 2½%, in addition to the prices mentioned above, may be charged by brokers, dealers and merchants.

The prices mentioned in this Schedule are for oil delivered free on rail or barge at the sellers' works or at the nearest station or wharf into the purchasers' tank cars and sold according to the producers' weights and measurements. In cases where the seller supplies the tank cars, an additional charge of 20s. for each 2200 gallons capacity per week for the use of such cars is permitted.

In the case of oil delivered from such ocean installations as shall be approved by the Minister of Munitions, an additional charge of 1d. per gallon is permitted, which increase shall cover all charges for insurance, pumping, and such other expenses as are usually defrayed by the purchaser.

The cost of analysis, measurement and sampling may be charged to the purchaser in addition to the maximum prices above specified.

The cost of barrels (including coopering and filling) and the barges used for transport may be charged for at current rates.

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council desires to remind intending competitors for the Cross and Bevan prize that Essays must be received at the offices of the Society before the close of the present year.

The Essay prize is open to all members of the Society who are British subjects. The Research Grant is limited to competitors under 25 years of age at the time of sending in the essay.

Full particulars were published in the issues of the Journal for 15th January and 15th and 28th February, 1917.

PROHIBITED EXPORTS.

An Order-of-Council, dated 18th October, 1917, makes the following alterations in regard to prohibitions of export* :—

The following headings are deleted :—(A) Aluminium, alloys of aluminium and manufactures of aluminium; (C) Arsenical ore; (C) Arsenic, compounds of arsenic, and mixtures containing arsenic; (A) Cresol, compounds and preparations of cresol (except saponified cresol) and nitro-cresol; (B) Cresol (saponified); (B) Lead ore; (B) Belting, hydraulic leather, pump leather and leather manufactures suitable for textile machinery; (B) Oil, fish and seal, not otherwise prohibited, and mixtures containing such oils; (C) Oils, essential (except turpentine oil); (C) Paper, Japanese tissue; (B) Waxes, animal, mineral, vegetable, and composite waxes, not otherwise prohibited.

The following headings are added :—(A) Aluminium, alloys of aluminium and manufactures of aluminium, or of its alloys; (B) Arsenical ore; (A) Acridavine, proflavine, and other acridine derivatives having antiseptic or therapeutic properties, and mixtures or preparations containing any of these substances; (B) Arsenic, compounds of arsenic, and mixtures containing arsenic; (A) Cresol, compounds and preparations of cresol and nitro-cresol; (A) Lead ore; (B) Belting, leather manufactures suitable for textile machinery and leathers cut or shaped for hydraulic or pump purposes; (B) Oil, fish, not otherwise prohibited, and mixtures containing such oil; (B) Oil, sandalwood; (A) Oil, seal, and mixtures containing such oil; (C) Oils, essential (except sandalwood and turpentine oils); (C) Paper, Japanese tissue and similar cellulose paper, whether in the piece or roll or cut into shapes for domestic or other uses; (B) Sandalwood, for medicinal purposes; (B) Waxes, animal, mineral, and vegetable, not otherwise prohibited; (A) Waxes, composite.

APPOINTMENT OF PETROLEUM EXECUTIVE.

The Rt. Hon. Walter H. Long, M.P., has been requested by the War Cabinet to take control of all questions affecting petroleum oils and petroleum

products. Mr. Long has appointed Professor Cadman, C.M.G., Petroleum Adviser to the Colonial Office, to be his technical adviser and liaison officer between the various Government Departments. Professor Cadman will also take charge of an organisation which will be established for giving effect to Mr. Long's instructions, and will assume the title of Director of the Petroleum Executive. Mr. B. S. Shrapnell-Smith, Chairman of the Joint Committee of Mechanical Road Transport Associations, has been appointed Economy Officer to the Petroleum Executive, and he will be concerned in introducing economies both in H.M. Services and in the civil use of petroleum and petroleum products. The headquarters of the Petroleum Executive are at 8, Northumberland Avenue, London, W.C. 2, to which all communications should be addressed.

Sir Beverton Redwood, Bart., Director of Petroleum Research, has been appointed to be Director of Technical Investigations in the recently created Petroleum Executive, with a view to his dealing with technical questions of the highest importance, including the co-ordination of the work of petroleum production and that of petroleum research. Sir Beverton Redwood will cease to act as Director of Petroleum Research.

NITRATE OF SODA AS "WAR MATERIAL."

The Minister of Munitions has made an Order, dated 19th October, to the effect that the war material to which Defence of the Realm Regulation 30A applies shall include nitrate of soda. All applications and communications in connection with the Order should be addressed to the Department of Explosives Supply, Ministry of Munitions, Storey's Gate, Westminster, London, S.W. 1.

Liverpool Section.

Meeting held at the University on Friday, October 19th, 1917.

MR. A. T. SMITH IN THE CHAIR.

SOME PROBLEMS CONFRONTING THE CHEMICAL INDUSTRY.

BY A. T. SMITH.

It is difficult perhaps to detach one's mind from the turmoil of events, but in such times as the present it is desirable and even essential occasionally to ignore what is going on day by day, and to endeavour if possible to look at the end. So it occurs to me that after three years of war it may not be unprofitable to pause and consider the changing phases of the chemical industry arising out of the extraordinary demands for munitions of war, as well as the constitution of a Ministry of Munitions and a Government which has assumed autocratic powers rivaling anything which has before occurred in our history.

I propose, therefore, in these few remarks to endeavour to discuss some of the problems which face us. Let me say at the outset that my object is not to criticise the action of the Government opposite the Chemical Industry, but to consider the conditions that have arisen owing to the systems of control which have been instituted, and to suggest, if I may, possible dangers to the

* The prohibition of exports is as follows :—

Goods marked (A), to all destinations;

Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

interests involved, from the point of labour as well as capital.

I remember many years ago listening to the inaugural address of Mr. Eustace Carey when Chairman of this Section, and if I recollect rightly the title of his paper was "The Invasion of the Inventor." To-day I think we are faced with an equally important problem, which I may perhaps describe as "The Invasion of the Official." This phrase is self-explanatory, but it indicates a new condition of affairs, entirely foreign to English methods of business or lines of thought, which gives much concern to those who are engaged in the conduct of large or small business enterprises. Up to the commencement of the war these may with justice be considered to owe their success to individual effort, divorced entirely from official guidance or interference, except in questions of the most abstract and non-controversial nature, such as the work of the Alkali Inspector or Factory Act Inspector, whose visits in all well-conducted works have been cordially welcomed.

The new condition of affairs arising from the creation of the Ministry of Munitions has, as we all know, brought in its train an army of officials, and a multiplicity of orders and forms which make it well-nigh impossible for some of us to give that attention to our daily work which is really called for, for the simple reason that time is largely occupied in attempting to comply with the wishes of these various new departments. It may be that this condition of affairs is inseparable from the control of manufacturers by a central department or departments in London, but I venture to suggest that rites and ordinances have been multiplied to an unnecessary degree. In the early months of the war, when the departments were in their infancy, this was not so much the case, and a great deal of useful work was promptly carried out. But undoubtedly red tape has grown apace lately, and is at present a serious drawback to the prompt despatch of business. In some cases the difficulties brought about in this way are almost insuperable, with the result that the products required are not forthcoming when they are wanted, in spite of every effort and desire on the part of individual manufacturers to carry out instructions as promptly and as quickly as possible.

A Ministry of Reconstruction has now been inaugurated, and it may be imagined that the mantle of the Minister of Munitions is eventually intended to fall on the shoulders of the Minister of Reconstruction. A Committee consisting of members of the Association of British Chemical Manufacturers has been nominated by the Minister to confer with officials nominated by him as to the method of procedure to be followed in carrying out the work of his department of the Government.

I think that this question of multiplication of officials and forms is one which the Committee should consider and deal with almost before any other, with the object of getting back to practical and business-like methods as promptly as possible.

Centralisation is all very well in its way, but in a trade like ours I venture to suggest that too much centralisation is worse than useless. The products we have to deal with are so many in number, so interdependent, so varied in their characteristics, the various qualities of even the same articles have such different properties and are required for so many different operations, that no man, unless he is actually employed in the business, can have anything more than a superficial knowledge of anything but a very limited number of them. The control of the manufacture of such products is therefore perhaps best left in the hands of the men who understand them and have devoted their lives to the study of their characteristics.

I am afraid that the British habit of self-depreciation has grown so much upon us that we are at last beginning to believe all that we say about ourselves as well as all that our enemies say about themselves. In rendering homage to Germany's great panacea for everything, "Organisation" (which I have heard described as being the docile disposition of the German people which enables them to submit to *being organised*), we have lost sight of the one quality which has always been the sheet anchor of British character, namely, "Individuality." I think it is time we should recall this to mind.

Organisation is undoubtedly useful, but I submit that it is possible to have too much of it, and whilst it is considered to be a defect in this country that we have not had enough organisation, I think it will be admitted that in Germany there has been too much. I will not go so far as to say that this is a case of cause and effect, but I do suggest that if there had been more of British individuality in Germany there would have been less of that docile submission to authority which has resulted in the whole nation being led by its rulers over the precipice which is leading it so rapidly to destruction.

Individual freedom is, in my opinion, the one quality which has enabled England to remain in the forefront of the nations, and to overcome in this war, as in former wars, the enormous difficulties which have arisen. Certainly no organisation on earth could have possibly overcome them so fully and completely in the time, had it not been backed by this individuality and initiative, which is our most valuable asset. If as a result of this war we adopt in England systems of control and State interference which are so rampant in the land of our enemies, we shall do so at the expense of that individuality which I say again is our most valuable asset, and we shall in effect be no better off then if we had lost the war.

I feel sure that the greatest dangers are in front of us if we do not, as soon as ever possible after the war, reassume or resume that individual liberty of action and freedom of initiative which has been temporarily suspended. It is not as if this state of affairs had never existed in the world before. This usurpation of the liberty of the subject is not a new thing in the world's history. Other nations have arrived at a condition of affairs which is exactly parallel with that which exists in England at the present day, and for the self-same reason—militarism. I will give one example from the history of Rome, describing the latter days of the Augustan era, which reads as follows:—

"The Roman Empire had already lost, and had never been able to restore, its prosperous farming class. It now lost likewise the enterprising and successful business men of the middle class. Diocletian therefore endeavoured to force these classes to continue their occupation. He enacted laws forbidding any man to forsake his lands or occupation. The societies, guilds, and unions in which the men of various occupations had long been organised were now gradually made obligatory, so that no one could follow any calling or occupation without belonging to such a society. Once a member, he must always remain in the occupation it implied.

"Thus under this oriental despotism the liberty, for which men had striven so long, disappeared in Europe, and the once free Roman citizen had no independent life of his own. For the will of the Emperor had now become law, and as such his decrees were despatched throughout the length and breadth of the Roman dominions. Even the citizens' wages, and the prices of the goods he bought or sold, were as far as possible fixed for him by the State. The Emperor's innumerable

officials kept an eye upon even the humblest citizen. They watched the grain dealers, butchers, and bakers, and saw to it that they properly supplied the public and never deserted their occupation. In some cases the State even forced the son to follow the profession of his father. In a word, the Roman Government now attempted to regulate almost every interest in life, and wherever the citizen turned he felt the control and oppression of the State."

This quotation is from a recently published book, called "Ancient Times: A History of the Early World," by that eminent American historian, Professor James Henry Breasted. It is worth giving this extract at length because the description might with absolute justice have appeared in the pages of any of our daily papers. If there is any truth in the maxim that history repeats itself, we shall have to take very great care that the British Empire does not follow in the steps of the Roman Empire, which very shortly after it had arrived at the state of affairs recorded above was plunged into a revolutionary period, resulting in the destruction of civilisation for hundreds of years.

There is no need for me to expatiate on this extract. The parallel is so accurate that no criticism is called for, and it is because the cases are so similar that I do want to emphasise the danger which, in my opinion, faces us unless we, whilst acknowledging the need of some control, retrace our steps as quickly as ever possible, and resume our liberty of action and freedom. We constantly hear the British soldier extolled as compared with his Continental opponent because of this very initiative which he possesses and the other does not. It would be lamentable in the extreme if England as a nation were to degenerate into a body of drilled units, with no will of their own and no mind except to obey orders. It becomes, therefore, almost a question of the psychology of the two races and of the systems which prevail and the methods of thought which are suited to the different communities. The systems will, I think, be judged by their works, and I think also that our want of organisation, bad as it is, is proving itself infinitely better than the German super-organisation, owing to the saving grace of initiative and individuality.

I hope, therefore, that as soon as ever the pressure can be relaxed the bondage of control will be done away with, and that we shall be permitted to go about our business more or less in our own way as formerly.

There are doubtless some good points about organisation and discipline, but at the present time I am afraid we have gone very much too far in that direction. I can see some good points in a limited supervision of manufacturers, but every one of those points is simply bristling with difficulties.

The recent formation of the Association of British Chemical Manufacturers is a step in the direction of commercial organisation which may have a very important effect on the future of the chemical trade. It has been brought about by the desire on the part of chemical manufacturers in this country to endeavour to sink their differences as far as possible for the common good; to avoid over-production and duplication of plants in view of the scarcity of capital, which is the natural result of the extraordinary expenditure occasioned by the war; and by closer co-operation one with the other, and one branch with the other, to oppose a united front to the cartels and rings which have been in existence for so many years on the Continent, with the one object of furthering our adversaries' trade to the detriment of the trade of every other country in the world.

The Association has already succeeded in modifying certain new Ministerial Regulations

which would have been very detrimental to the industry if promulgated in the form originally intended, and its status has been recognised by the Government. The various sections of the trade have been assembled into group systems which are settling down to regular work, and I am sure that excellent results may be looked forward to in due course.

But the threatened danger is to be looked for in more directions than one. The present attitude of labour is a very serious menace to the industry. Large numbers of men, as we know, volunteered for active service in the early days of the war, and in the enthusiasm of the moment and in ignorance of the magnitude of the undertaking facing us, they were accepted indiscriminately by the Military Authorities, and sent to the front as quickly as possible. The result was that many works were almost denuded of their best men, and have in consequence been working under a severe handicap ever since, owing to the impossibility of replacing these men with any others but those inexperienced in their particular processes and inferior in many other respects. When the call came for an increase of output it was found difficult to respond owing to the serious handicap of the lack of experienced men who, for various reasons, it was found impossible or inexpedient to bring back from the front, and the works in consequence have been obliged to do as well as they could without them.

There was a scarcity of even these inefficient substitutes and in consequence a demand arose for higher wages. The Unions have lost no opportunity of increasing their membership, and now we are faced with a labour organisation which bids fair to rival the official organisation in its "genius" for control and regulation of expenditure.

I would not like it to be thought for a single moment that I am opposed to the labour movement. I am quite in favour of giving the labouring man every conceivable privilege consistent with the rights of others. I would go, and have gone, a very long way in the direction of improving his conditions of living. But I have an uneasy feeling that the leaders of labour in many instances, as well as most of the members of the Unions, have failed to realise that higher wages and shorter hours carry with them the moral and actual obligation of more conscientious and better work. I wish that they could be persuaded to see that the true interest of the working man lies in the direction of individual effort resulting in increased output, in other words every man doing his best to get the most work out of the machines supplied instead of the least, or in any case only a dead level of mediocrity.

If the workers would only try to look at things from this standpoint and act accordingly I should feel more hopeful for the future, and particularly if they could become imbued with the spirit of the old Guilds, the prototypes of the Trade Unions in the Middle Ages. In those days the Guilds were even closer corporations and governed by more severe rules than the Trade Unions are to-day, but there was this important difference. No man was allowed to become a member of a Guild or work at his trade until he had served a real apprenticeship and even then was not allowed to become a journeyman until the Masters of the Craft were satisfied that he knew his business and produced a proof of his ability in the shape of a specimen of his work, called because of this a "masterpiece." How many full members of Unions would pass this test to-day? How much better it would be for us all if the workman of the present day took the same pride and interest in his work as the craftsman of the olden time and how much better off we should all be both physically and morally!

Money is not everything and the true measure of a man's happiness is not always the amount of money he takes home every week end, though many will say that it is. None can deny that it is a most important consideration, but I do suggest that the happiest and most contented man is the one who knows how to spend his money intelligently, who does not waste his money however large or small. Above all things he does not waste either his own time or his employer's in unprofitable idleness, but on the contrary spends his own spare time in useful outdoor work or recreation, and in the improvement of his education. When at his work he is diligent and attentive to his duties, bearing in mind the Scriptural admonition to give "full measure, pressed down and running over." I can assure you the plan is a good one—it pays; and the only ones who do not understand and do not believe it are the ones who have never tried it.

It comes back therefore to the original idea "Individuality," and each man must work out his own salvation; there is no golden rule for any of us but to work.

On the other hand the labourer is worthy of his hire, and he has not unreasonably a desire to participate in the profits resulting from his labour. Many attempts have been made to devise schemes which would satisfy this very laudable ambition, but I am afraid that many, if not most of them, have failed largely because the working man failed to realise that "to great privilege great responsibility is attached." Although he is quite willing to accept any extra remuneration, call it profit-bonus, or dividend, or profit-sharing or what you will, he appears unable to realise the duty which in turn is incumbent upon him. He should give reasonable attention to his work and refuse to waste his employer's time, which bear in mind he is paid for, and contribute what in him lies to the power of his employer, to increase or earn that profit and so pay the same or an increased profit-bonus or profit-sharing dividend.

The question as to whether a man should work eight or six hours a day is, I am afraid, more in the region of ethics than practical politics at the present time, when men are daily giving their lives ungrudgingly in defence of that freedom which has made England what she is. It seems to me that a man's duty to-day is not to consider how few hours a day he can devote to work or how many to recreation or enjoyment, but for how many hours he can do honest work to produce the maximum output and help for his comrades at the front, and what is the least time his conscience will allow him for his own ease or refreshment.

With regard to profit-sharing, and to illustrate the difficulties which confront employers who with the best will in the world want to help their men to take an intelligent interest in their work, I will give two instances:—

One is the case of a firm which instituted a bonus scheme by virtue of which a certain percentage of the wages paid was put by every year for the men in their employ, the percentage increasing with the length of service. The money so accumulated was invested by the firm and became payable to the man or relatives after he left their employ or at death. Obviously the object of this scheme was to encourage faithful service and to give each employee an interest in his work and a desire to remain at his post. What was the actual result? It was found that when a man had accumulated a substantial sum, say £50, he suddenly discovered that he wanted to leave. The result was that he drew his bonus and the main object of the scheme was defeated.

In another case a Company carrying on a satisfactory trade was approached by the men with the suggestion that they would like to have a share

in the proceeds of the business. The Directors considered the matter and came to the conclusion that, although they already paid the full Trade Union rates of wages, the request was not unreasonable. They endeavoured to meet it by paying the men after a certain period of employment a bonus calculated on the rate of dividend paid to the shareholders. It was hoped that the men would realise that this was an endeavour to identify the interests of the employees with those of the employer, and that the men would give a conscientious return for the concession made by increased diligence and attention to their work, avoidance of waste, and careful supervision and attention to their own particular section. The bonus is paid monthly and at the present time represents an increase of over 20% on the wages paid. This monthly payment was instituted to obviate the objections which arose to the system already referred to and which defeated its own object by giving the men an inducement to leave after a certain period instead of to stay on. Instead of the hopes of the Directors of this Company being fulfilled, the only practical effect appears to be, that with the exception of a very small percentage of the men, there is no result at all, except the handing over of a sum of money at the end of each month to the rest of the men. This they take without any appreciation as to why it is given to them, and without any effort at all on their part to make any return for the consideration shown to them. Labour troubles are just as common in this works as they are in other works in the neighbourhood paying lower rates of wages, without any bonus. Individuals on being questioned have no hesitation in saying that whilst they like to get the bonus they have no idea why it is paid, and have no notion that they are placed under any obligation to do anything except perform their work in the sloppiest and most perfunctory manner. They consider the employers have a very good reason for paying the bonus, and that they would not do it unless it was worth while, and so on. This is very disheartening, and makes it very difficult for employers who honestly want to help their work-people and to institute conditions which will be satisfactory to them and remove feelings which give rise to unrest and suspicion.

Personally, I am inclined to think that the trouble lies partly at the door of the education authorities and partly at the door of the Municipal and Urban and Rural District Councils. The education authorities, because they do not inculcate rules and present ideas to the children in the schools which will have a tendency to raise them above their surroundings and make them want something better. The girls are not taught to cook, and know nothing worth the name about housekeeping, with the result that when they do get married the unfortunate man who happens to be their husband is considered by them to be nothing whatever but a provider of money, which may or may not be wasted according to the whim of the moment. Instead of a comfortable home, clean and cheerful, he too often returns to a disorderly kitchen, an untidy wife, and an unsatisfactory supper.

This is where the education authorities are at fault, and they are generously helped by the local authorities. These bodies permit houses to be built for workmen to live in which are lacking in space, crowded together to a disgraceful degree, with no light, no air, and no land which can be turned into a garden so that the man may have some intelligent occupation for his spare time which is essential if he is to be kept in a state of health and happiness.

Perhaps, however, the fault lies more at the door of the municipal authorities than at the door of the education authorities. If the building

rules were much more stringent, if the specifications for workmen's dwellings were liberally improved upon, provision of adequate cubical capacity in the rooms, adequate air, light, and water, as well as land, were insisted on, the general condition of affairs would be improved. The man would become a better workman, and the master could afford to pay him higher wages because he got a better return, and in the end both parties would benefit, because the man would have more and a higher interest in life than at present.

It may be argued that the provision of this better housing accommodation is a very big financial proposition. Perhaps it is, but this is not an insuperable objection, and in many cases individual employers would be only too glad to assist in this direction if they felt that they could rely upon any return for their money. It is difficult to apply such conditions in the neighbourhood of many of the works which exist at the present time because they are already crowded out with dwellings, and there is no remedy short of pulling down and rebuilding.

Such conditions could be applied in the case of works which are being established in new neighbourhoods, and as we know they are being applied in this neighbourhood with very beneficial results.

I am perfectly certain that the object-lesson is not being lost sight of by other liberal-minded employers who are anxious to do everything they can to make the lives of their workpeople as happy as possible.

Probably, if it had not been for the advent of the war, many schemes for the improvement of housing accommodation would have been already in operation, besides the one to which I have referred. Here again stern necessity brought about by the war has rendered it impossible to continue the erection of new buildings or to provide even sufficient housing accommodation of the ordinary sort to meet the constantly-increasing demand. It may well be that before very long it will have to become a Government charge to see to the erection of such buildings, even to the extent of providing financial assistance towards the project. This, to my mind, would be a great pity, because such things are better if left in the hands of private enterprise. But that the problem will have to be tackled soon, and on a large scale, seems to me absolutely undeniable.

I will conclude with a few words on the University training of chemists, on whose fitness for their work the success of the industry so vitally depends.

It seems to me that a works' chemist, to be a success, besides accurate theoretical knowledge of his subject, should, when he leaves the University, be armed also with a practical knowledge of the economical problems which confront the manufacturers in his particular branch of the industry.

There is a charming irresponsibility about many young men who come to a works with their University honours fresh upon them. They have been accustomed in their laboratories and in their studies to regard substances and processes almost solely from the point of view of their atomic weights and chemical characteristics and without any regard to their monetary values. This is inevitable perhaps because, from the very nature of the case, they carry on their experiments with no regard to the cost of the reagents or apparatus employed. I do not mean to suggest that problems are never expressed in terms of "£ s. d." as well as in the chemical nomenclature, but I do suggest that in the laboratories there is a tendency to consider almost exclusively the theoretical side without any serious attention to the monetary value of the problems, processes, operations, and reagents involved.

It should be borne in mind that invaluable as theoretical knowledge is for its own sake, its value

really depends in the long run on its power of being translated into terms of money. This important consideration should therefore, I think, be kept well in the foreground, so that students coming into a works from the University shall be armed with the knowledge which will enable them to view things with a due sense of proportion. The information could be easily obtained by the study of the value of chemical substances as set forth in the weekly trade circulars published by those engaged in the trade and in the technical and other papers.

Finally, I would ask forbearance for the very general nature of the few points I have brought forward. Just now it is rather difficult to deal with any of the extremely important technical problems with which we are all at the present time so deeply concerned because as law-abiding subjects we by no means desire to trespass against any of the ordinances which our rulers in their wisdom have set up as worthy objects for our respect and admiration.

DISCUSSION.

Mr. T. W. STUART entirely agreed with the author's remarks on Government interference and its detrimental effect in cases where individuality untrammelled and with a free hand could alone produce the best results; he trusted that after the war the views and hopes of Mr. Smith would be realised by a return to conditions of individual and private enterprise without excessive State control. With regard to difficulties between capital and labour, he was of the opinion that the next five years in the chemical trade would be more strenuous than ever, and hence the greatest efforts of the representatives of labour and of the masters and of the Government would be required to keep the men in hand and to cope with manufacture. The war of 1870 had been the cause of a period of great prosperity for the chemical trade, lasting about two years, during which time prices rose and wages were increased; but labour became absolutely disorganised, and it was 12 years before the increase of wages was reduced by one half. Men of the widest experience and talent would be required to manipulate the situation after the present war if this country were to recuperate after the stress and strain of her present gigantic task.

Dr. E. F. ARMSTRONG said that every word the author had spoken was true in regard to the ways of officials; the lives of technical chemists had become a burden during the past three years, for half their time was wasted in having to deal with Government and other representatives who were ill-trained and unable to understand the mental attitude of the expert chemist—whose outlook on technical matters was specialised and entirely different from that of any other type of professional man; the other half of their time was absorbed in difficulties connected with labour. Referring to the University training of the chemist, he (the speaker) disagreed with Mr. Smith on the question of teaching the student the economical side of chemical manufacture before he entered the works. Year by year the young men were being sent from the Universities better equipped, and obviously the future works-chemist should thoroughly know his science first, and then on entering the factory he might develop and eventually, if capable, he would become the required article. Those "Admirable Crichtons," who would revolutionise the monetary side of a process in three months after coming to a works were very few and far between—if not impossible to find.

Mr. JOHN GRAY said that there had never been such a time for chemical industry as the present, *i.e.*, such a time of unprecedented demands and difficulties of execution, so that the interruption

from officials was highly annoying. It was interesting to read in a report of the German Iron and Steel Institute (translated by Sir Robt. Hadfield) a condemnation of the methods of "organisation" in that industry—the writer complaining of a "superabundance of Government departments." The speaker thought that broad-minded dealing between labour representatives and employers would result in a better state of affairs in industry after the war, when wages would still be high, as also would be the cost of living, but if manufacturers combined together for increase of production then the payment of high wages would be justified.

Mr. W. MANSBRIDGE thought that the adjustment of differences between labour and capital was of vital importance to reconstruction after the war; if workmen were more conscientious and gave of their best to the employers there would be no need for Trade Unions, because masters and men would automatically assist each other. Boilermakers and others in the engineering trades were setting a very bad example by their "ca' canny" tactics. Finally, with regard to the young works-chemist, there was a reluctance to pay him an adequate salary, still to be observed in some works; this was a very uneconomical practice since it tended towards a low standard of efficiency.

Mr. EDWIN THOMPSON felt that the general tone of Mr. Smith's remarks was pessimistic, *e.g.*, it was rather depressing to an Englishman to have ancient Roman history quoted against him. He (the speaker), while realising that the lecturer's remarks were intended to arouse deep thinking among chemical manufacturers, at the same time would have liked to hear Mr. Smith suggest constructional details towards an after-war policy.

Mr. A. T. SMITH, in reply to Dr. Armstrong, submitted that the element of "cost" should not be ignored in the University training of the works-chemist. He hoped that good would arise out of the war, in the way of amelioration of the conditions of manufacture and in better house accommodation for the workpeople, as also in the direction of improved relations between masters and men being permanently established.

Communication.

FURTHER EXPERIMENTS ON THE COMBINED SULPHUR CONTENT OF SLOW AND FAST VULCANISING PLANTATION PARA RUBBER.

BY B. J. EATON AND F. W. F. DAY,

Experimental Vulcanising Laboratory, Agricultural Department, Federated Malay States.

In a previous paper (this J., 1917, 36, 16.) we anticipated that a general agreement would be found to exist in the combined sulphur content of vulcanised rubbers showing the same state of cure as determined by the load-stretch curves. Further we showed that in the case of "slab," unsmoked sheet and crêpe prepared from the same latex (optimum time of cure 13½ hours, 2½ hours and 3½ hours respectively), coincident load-stretch curves of the three types obtained at different times of cure as above corresponded to substantially the same combined sulphur content. It remained to ascertain whether certain small differences could be attributed to a general higher combined-sulphur content in the case of fast-curing rubbers, such as slab and sheet compared with ordinary crêpe.

The combined sulphur of some thirty samples of vulcanised rubber at the optimum state of cure as determined by our standard optimum load-stretch curve was therefore estimated. Some of these rubbers were vulcanised from samples submitted for vulcanisation tests by estates, others were the normal experimental samples of our own factory, while others again were prepared by special methods. With such variously prepared samples it can reasonably be expected that the figures are fairly representative of first-grade plantation Para rubber. The optimum times of cure (O.T.C.) varied from 1 to 3½ hours; the mixing employed was, as before, 10% sulphur and 90% rubber, and the temperature of curing was 140° C. (this temperature applies to all our work on vulcanisation).

Method of estimation of sulphur.

The method of estimation of the combined sulphur is that described in our previous paper above referred to. A small improvement in the method should first be recorded. It was found that if a strand of platinised asbestos was laid lengthways along the paper packet containing the sample, before pushing the latter into the inner combustion tube, the last stages of combustion to a white ash were considerably hastened. In addition, the presence of the strand of platinised asbestos, which was looped back over the mouth of the inner combustion tube, caused a quick initial ignition, thus avoiding the necessity for the rapid current of gas originally advised.

Combined sulphur content at optimum time of cure.

In Table I. are set out all the details regarding the samples investigated. In column 4 of this table the percentages of combined sulphur found are enumerated, while in column 5 certain of these percentages have been corrected. The corrected cases are those in which the load-stretch curve did not *exactly* coincide with the standard. The basis of correction was as follows:—Near the optimum time of cure an extra period of cure of 15 minutes increases the combined sulphur content of crêpe by about 0.3%, of sheet by about 0.5%, and of slab by about 0.7%*. Again the same amount of curing, *viz.*, 15 minutes near the optimum time of cure, causes a shift in the load-stretch curve near the breaking point of about 8 mm. for crêpe, 10 mm. for sheet, and 12 mm. for slab on the scale employed (see Diagram 1). Hence 1 mm. is equivalent to 0.4% sulphur in crêpe, 0.05% in sheet, and 0.06% in slab. So long as this simple "rule of three" method of correction is restricted to very small intervals it may be regarded as accurate.

Column 7 shows the variations in the thickness of the vulcanised test rings; but in these experiments no connection can be traced between the thickness of the test rings and combined sulphur content at optimum time of cure. Other experiments which have not yet been published show that a relationship does exist between the thickness of the test ring and the load-stretch curve, those for thicker rings appearing more curved.

In Diagram 1 the curves are our standard O.T.C. curve (X) and the curves of the two samples in the table showing the greatest deviations therefrom. The average rate of curing is also made clear, a maximum separation between curves of about a centimetre corresponding to 15 minutes' curing. This is conveniently measured near the breaking point, when the curves are approximately parallel.

Diagram 2 shows two curves of somewhat irregular type and it may be noted that in the present samples, such irregularities as exist, lie in the direction of increased curvature. So far

* Figures taken from standard combined-sulphur content curve (this J., 1917, Vol. XXXVI. No. 1).

this question of curve irregularity has not been followed up at all closely, but it is possible that the determination of the combined sulphur content of a fair number of samples showing irregularity in various directions, might throw considerable light on the problem of vulcanisation.

In Table II, the results are arranged according to the number of hours of vulcanisation, and, where more than one figure is available, the average percentage of sulphur is set out for each time of cure. Here the necessity of dealing with average, instead of separate figures was forced upon us by the comparatively large individual variations between the samples. The magnitude of these variations is sometimes nearly as great as the sulphur content differences at O.T.C. existing

TABLE II.

*Where original and repeat figures are available the mean value is brought forward from Table I.

between slab and crêpe, so that only by averaging is it possible to make these type-differences stand clearly out. Diagram 3 shows how the combined-sulphur content falls at an increasing rate as the optimum time of cure increases, the figure for one hour being the only important exception. While only average results are shown on the diagram (for it is not possible to attach much importance to individual figures when averages have been used as the basis of the curve), yet it will be seen that the one-figure results available fit into the curve fairly well. The large number of results now available enable us to widen our originally suggested limits for sulphur content, viz., from 1%—1 1/2% to 3.7%—4.6%. As against this extension of the limits it may now be stated that ordinary crêpe (optimum time of cure about 3 hours) falls between 3.7% and 4.1% and slab between 1.2% and 4.6%.

Other recently published results.

Schidrowitz and Goldsborough in a note in the India Rubber Journal (April, 1915, 51, 505; see this J., 1916, 550) gave nine results for combined sulphur at "correct cure," the figures ranging from 2.03 to 4.86%. Later, in the same journal, de Vries published further figures on the same subject (this J., 1916, 1226; 1917, 296); his figures, however, like our own, cover a range of about 1%. Further, of the nine figures published by de Vries, five relate to first latex crêpe and the range here is less than 0.5%; his other figures refer to samples coagulated by heat, smoking, etc. The fact that the range of de Vries' figures is similar to our own is important; the actual percentage of sulphur is of secondary importance, since de Vries vulcanises at a different temperature, viz., 148°C., and uses a different rubber-sulphur mixing, viz., one containing 7.5% of sulphur.

Relation of vulcanisation coefficient to physical properties.

De Vries claims "that he has definite proof that the percentage of combined sulphur is quite independent of the state of cure as expressed by the position of the stress-strain curve, and that it is possible to bring the rubber to the 'correct' or to any chosen standard cure (as judged by the curve) with other and quite arbitrary coefficients of vulcanisation." He produces, by vulcanising for one hour, a much undercured rubber containing only 2.85% of combined sulphur and subjects it to a temperature of 70°C. for 11 × 6 hours. In this way the sulphur content remains practically constant but the physical properties undergo a very marked change.

The stress-strain curve now indicates a correctly cured, instead of a much undercured rubber. "The same position of the curve (correct cure) is reached" in the ordinary way by curing for 1 hour 40 mins. but in this case the combined sulphur rises to about the ordinary figure, 4.49%. According to this treatment it appears that samples can be produced containing almost any percentage of sulphur up to, but not exceeding the normal figure obtained by direct curing; for from the experiments described it does not appear that samples can be made to contain more combined sulphur than their normal figure. We are not on the present evidence prepared to regard it as proved "that the mechanical properties (position of curve) and the coefficient of vulcanisation are two independent qualities of the vulcanised product." It may well be that two very different vulcanisation products are produced. The product with the abnormally low sulphur content is apparently an undercured rubber which has undergone what really amounts to an accelerated

ageing period. Instead of allowing vulcanised samples to stand for several months at ordinary temperatures de Vries employs a few days at 70°C. and instead of ageing a normal product he ages an undercured specimen. The ageing effect thus obtained, instead of deteriorating a correctly cured rubber, improves the physical

properties of an undercured one. A vulcanised product prepared in this way may or may not answer the ordinary purposes and fulfil the ordinary requirements of vulcanised rubber. De Vries does not publish the curves obtained from these low sulphur-content products, but one assumes by the expression "the same position of the curve is reached" that the curves are coincident, or, at any rate, are identical in type. Such identity even may be fortuitous and the mechanical properties in the wider sense of the term may be far from identical.

Our own work on ageing samples of crumbed vulcanised rubber indicates that the sulphur falls (possible loss of sulphur as SO_2 as well as ascertained accumulation of sulphuric acid in the rubber which means loss of sulphur as such), so that these low-content products may be produced by the decomposition of sulphur and rubber already combined while, *pari passu*, slow combination of free sulphur may proceed to an approximately equal extent thus keeping the combined sulphur content at the same level.

We have also stated in a previous paper (this J., 1916, 35, No. 20) that when the vulcanised product is tested almost six months after vulcanisation, the shifting of the curve, in the case of undercured, correctly cured, and slightly overcured samples (as determined by the load-stretch curve obtained by testing the samples three days after vulcanisation) represents an extra cure of about $\frac{1}{4}$ hour under the conditions of vulcanisation employed. Whether the combined-sulphur content changes, we have not yet determined in our own samples aged in this way. Experiments on a large number of samples containing different amounts of total sulphur and covering a large range of under and overcuring, are now being carried out, the samples being left at ordinary temperatures for periods of six months and one year. It is hoped by these experiments to throw more light on the question of ageing of the vulcanised product. De Vries' experiments are, in our opinion, essentially accelerated ageing experiments, and may be of considerable value from the point of view of a rapid method of conducting such tests. Our experiments, referred to above, indicate that, in order to obtain a vulcanised product which ages satisfactorily, a cure of about $\frac{1}{4}$ hour less than that given to the samples which yield maximum tensile figures when tested within three days after curing, should be employed. Very recent experiments, in which the vulcanised specimens were tested 2 hours, 1 day, 2 days, and 3 days after vulcanisation show that the shifting of the curve within these limits is slight and represents an extra cure of about 2–3 minutes under the conditions of vulcanisation employed. The last period, viz., three days' rest between vulcanisation and testing, is that adopted in all our experiments hitherto. It would be instructive to know whether the total sulphur content remains constant. Moreover from the purely theoretical standpoint, the fact that one cannot prepare an apparently correctly cured sample containing more than the normal amount of sulphur certainly indicates that some interdependence exists between physical properties and combined-sulphur content.

developments. The chemical industry in Japan has shown great expansion since the commencement of the war, during which period at least 20 new companies have been formed, with a combined capital of approximately £3,000,000. These new companies operate some 28 factories, and among the chief productions are ammonium sulphate, potassium chloride, caustic soda, bleaching powder, nitre, potassium sulphate, potassium carbonate, sodium sulphide, sodium chloride, sodium peroxide, iodine, stearic and other fatty acids, nitric acid, glycerin, oils, dyes, drugs, fertilisers, disinfectants, phosphorus, etc. It is estimated that there are 80 firms in Japan engaged in producing potassium chloride. Large stocks of this commodity are on hand, the market is overstocked, and prices have dropped during the present year. Formalin is now being produced in Japan; the output is devoted to home requirements. One company is producing soda by means of electricity, and is stated to be the first concern in Japan to use an electrical process in this connection.

A company is manufacturing indirect dyes exclusively for domestic needs, while direct dyes are to be produced for the export trade. This company is under the regis of the Government. Another company claims to have produced an ultramarine blue equal to that formerly imported into Japan from Germany.

Metals.—The future of the zinc industry in Japan is generally considered to be exceedingly good, and it is expected that a large export trade will be carried on after the war. One company is manufacturing zinc for the export trade. Much of the Japanese zinc ore contains other metals, such as gold, silver, and copper, and the refining of these metals is carried on in conjunction with the treatment of the ore. Five new companies, with a total combined capital of £760,000, have been organised, and operate six works for the treatment of zinc ore produced in the country.

A company, with a capital of £100,000, was formed in March, 1916, for the purpose of producing aluminium. The process to be used, it is stated, is different from that used in Europe and the United States. Alumina is obtained from a clay which is a special product of Japan, and is treated by an electrolytic process.

A company was formed in January, 1917, with a capital of £10,000 for the purpose of manufacturing sheet lead for use in chemical industries. The company is turning out sheets measuring 10 feet by 4 feet, and it claims that its product is superior to any hitherto manufactured in Japan.

Paints.—Three new companies, with a combined capital of £90,000, have been formed for the purpose of manufacturing paints, the chief products being zinc and house paints, paints for ships' bottoms, antiseptic paints, rust-preventing paints, and paint substitutes. One company is producing zinc powder successfully, there being a good local demand; paints for ships' bottoms were previously all imported from the United Kingdom.

Oils and grease.—Six companies have been established, with a total combined capital of £1,645,000, for the production, refining, etc., of mineral oils. A company has been formed, with a capital of £25,000, for the purpose of manufacturing fish grease, used in the manufacture of soap and glycerin.

Sulphuric acid.—The increased export of sulphuric acid from Japan to Russia and China since the beginning of this year has led to steadily advancing prices of this commodity in Japan, and a considerably increased output. Several manufacturers of fertilisers have reduced their output, and are devoting their energies to the production of sulphuric acid, while a number of companies have been established for the production of this chemical alone. It is estimated

Industrial Notes.

JAPANESE CHEMICAL INDUSTRIES.

H.M. Vice-Consul at Tokiō has forwarded the following particulars as to recent industrial developments in Japan:—

Chemicals and dyes.—In point of numbers, the chemical industry occupies the first place in recent

that the rate of production of sulphuric acid in Japan at present is some 582,500 tons per annum. Of this quantity about 421,000 tons is consumed by manufacturers in the production of sulphate of ammonia, hydrochloric acid, etc., leaving some 160,000 tons available for general requirements in the country, which is about 100,000 tons a year. Thus there is about 60,000 tons available for export. It is taken for granted that on the conclusion of the war the export trade will fall off, and it is also probable that there will be a considerable decline in domestic requirements. It is estimated that the output of sulphuric acid in Japan, if continued at the present rate of production, will be some 100,000 tons in excess of the demand on the resumption of normal conditions.

Miscellaneous.—The following companies have been formed in various industries, the capital of each being shown within brackets:—

A company (£200,000) has been organised for the manufacture of imitation celluloid. It is claimed that the product, besides serving the same purpose as celluloid, can also be used as a substitute for lacquer, artificial leather and rubber, and also as a water- and heat-resisting material in constructional work. The material used is bean cake, and as this is both cheap and plentiful it will be possible to supply the imitation celluloid at a lower price than the real article.

A company (£100,000) has been formed to produce plate glass, and another company will operate a glass factory.

A company was formed in July, 1916 (£100,000), for the purpose of manufacturing explosives, and will produce dynamite for industrial as well as military needs. It is controlled by the Government and has been granted special facilities.

TUNGSTEN MANUFACTURE AT WIDNES.

An interesting account of the works recently erected at Widnes for the manufacture of tungsten, appeared in the Oct. 26th issue of *Engineering*. Our sources of supply of tungsten from abroad having been closed owing to the war, the Government sanctioned the erection of works for the production of tungsten powder; these works were erected by the co-operative action of a number of makers of high-speed steel, of which tungsten is so important a constituent. In order to secure an adequate supply of raw material, the High Speed Steel Alloys, Limited (the company controlling the works), has purchased mines of tungsten ore at Tavoy in Burma, where active development is in progress.

The ore used at Widnes is wolframite, which is received in the form of small cubes, which will easily pass a one-inch mesh. The ore is first sampled and assayed, and is then raised to a series of bins on a higher floor, lots of ore of different quality being kept separate. From these bins it passes to grinding machines and thence to calcining furnaces, magnetic separators, or fine grinding mills, according to its nature. Ores containing tin or bismuth are subjected to magnetic separation, the tungsten mineral being slightly magnetic. The finely ground ore is now mixed with the calculated quantity of sodium carbonate and the mixture heated to about 1000° C. in hand fired reverberatory furnaces and at the same time subjected to constant rabbling.

The ore mixture is selected to yield a uniform furnace product, as far as is practicable. The furnace charge is drawn off into slag pots, and when cool is broken up by hammers and then fed to a jaw-breaker, where it is reduced to about

1 in. cubes, and is then finely ground and the sodium tungstate extracted in steam-heated circular vats. The solution is passed through filter-presses and is then decomposed by hydrochloric acid, the tungstic oxide being washed by decantation, passed through centrifuges in which it is obtained in the form of a thick, yellow paste, and dried. Schedite, tin-tungsten slimes, tin residues mixed with small quantities of tungsten ore, and other residues are treated in a separate plant and the impure sodium tungstate purified before it is used in the main process. The tungstic oxide is reduced (the procedure is not described) and the metal ground to powder, washed, and dried.

Given adequate supplies of ore, the works are capable of producing daily three tons of tungsten powder of 99% purity—a quality higher than that obtained in the German product.

OPEN-HEARTH STEEL WORKS.

At the September meeting of the Iron and Steel Institute, reports were received from the Committee appointed to inquire into metallurgical and mechanical practice in open hearth steel works. In order to investigate the causes of the smaller output of British furnaces as compared with foreign practice, the Metallurgical Section of the Committee submitted a number of questions, the replies to which indicated that in foreign practice the proportion of scrap used—up to 80%—helps output materially in cold-charged basic open-hearth practice, if used in conjunction with suitable pig iron, which is generally low in phosphorus and silicon. *e.g.*, Si not over 0.75, P 0.15, S 0.05, Mn 2.0—4.0%. For hot metal it does not appear necessary to have so low a phosphorus content. *e.g.*, Si 0.4, P 1.8, S 0.06, Mn 1.25%. The process employed and the size of furnace are not deciding factors. Output in this country is greatly inferior to that abroad under comparable conditions in either of these respects. The question of special design of furnace is considered of great importance, and steps are being taken to prepare a standard design. The importance of general lay-out is also emphasised. There is a general opinion that the gas-producers are responsible for loss of output in this country, and that more care is devoted to them abroad. An abundant and regular supply of gas containing less than 10% of carbon dioxide (preferably less than 5%) is necessary. Labour conditions in this country, as compared with the Continent, are generally agreed to be detrimental to output; in fact it is considered that this factor contributes more largely than any other to low output. The stricter specifications required or the poorer raw materials are also believed to affect output. The importance of a supply of suitable pig iron is also emphasised. The following have also been put forward as causes contributing to larger outputs abroad: improvement of refractories; use of larger tap-holes; less time occupied in fettling and cooling furnaces for fettling; quicker charging. Some instances of increased output due to slight alterations in design of the furnace are recorded. A method of working basic open-hearth charges of all molten metal is mentioned, by means of which a 50-ton charge has been tapped in 7 hrs. 20 mins. from starting to charge; very little limestone and oxide are put in the furnace before the metal, and after the molten metal is charged, oxide and lime are fed in rapidly and continuously, thus causing the first impure slag to flush off.

The question of labour is regarded as a most

important one. The wages are so high that it is useless to expect men to make extra exertion to gain more. It seems, therefore, that in order to increase the output it is necessary to reduce the effort required from the workman by every possible means, and this can only be done by a

well-laid-out and well-organised plant. Output might also be improved by getting better educated sample-passers and foremen, and by encouraging more highly educated men to go in for melting. In view of the very handsome remuneration this should not be difficult.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron S. Paris (3e.).

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Extraction processes; Discontinuous.—L. F. Hawley. *J. Ind. Eng. Chem.*, 1917, 9, 866—871.

THE ratio between the volume of solvent drained off and that retained by the material to be extracted may be termed the *solvent ratio*. With any solvent ratio, a , a single washing will remove $a/(a+1)$ of the original substance, leaving behind $1/(a+1)$. In the case of n successive treatments with fresh solvent, the residual matter amounts to $1/(a+1)^n$ of the original. By means of these and other derived formulae, tables have been constructed showing the results respectively obtainable by repeated washings with fresh solvent, and by multiple series (counter-current) extraction. These results prove that the common belief is correct that in washing with a limited amount of solvent it is better to wash several times with small portions than once with the whole amount. For example, 4 vols. of solvent in 4 equal parts effect a better extraction (93.75% solvent ratio 1) than 10 vols. used all at once (90.9% solvent ratio 10). A greater proportion of soluble matter is removed per unit of solvent by multiple series extraction than by repeated extraction with fresh solvent. As a general rule, a somewhat less complete extraction, but greater concentration of solution, is obtained when the material is not saturated with solvent at the outset. In practice it has been found best to use sufficient solvent just to cover the material. If much more is used the portion above the charge is not utilised efficiently, and if much less is used the charge is unequally extracted. By giving two consecutive treatments with fresh solvent the concentrations of the solutions obtained will be essentially the same as those obtained by doubling the solvent ratio, but the percentage recovery is better. When high concentration is required, even at the expense of incomplete extraction, every alternate charge may be treated with fresh solvent, whilst every other charge is finally treated with solvent which has been used once before. The method in which each charge is treated with its own quantity of solvent independently, while shut off from the rest of the system, and the extractors subsequently connected while the solvent is pumped through the system, is essentially faulty. Mixing of the different lots of solvent takes place without concentration of the solution. To obtain a high solvent ratio, one charge of solvent must be drained off as completely as possible before the next is applied.—C. A. M.

Dryer; The Schilde "universal".—Parow. *Z. Spiritusind.*, 1917, 40, 13. *Bull. Agric. Intell.*, 1917, 8, 1034—1037.

A DRYING chamber containing a stack of ten

trays, one above another, is traversed by an upward current of hot air, drawn by a fan situated in the air-outlet at the top. Before entering the bottom of the chamber the air is warmed to 60° — 70° C. in a heater situated at one end of the apparatus. A second heater, situated between the fifth and sixth trays, divides the stack into two sets, and further heats the air to 85° — 95° C. before it passes through the upper set. The apparatus works continuously, each tray occupying in turn all positions from the top to the bottom. At intervals of about 20 mins. the lowest tray, containing the dried product, is withdrawn and after being re-charged with fresh material it is introduced into the top position. All the other trays then take up lower positions without being withdrawn, except the lowest one of the upper set which is transferred to the top position in the lower set; this affords an opportunity for turning the half-dried material. The withdrawal and transference of the trays is effected by means of an automatic hoist situated at one end of the apparatus and actuated by levers. The area of the trays is about 6 sq. metres and the drying of each tray-full of produce, *e.g.*, 120 kilos. of sliced swedes, occupies about $3\frac{1}{2}$ hours. The apparatus can be worked by one man and two women. Two are in use by the Berlin Corporation for the drying of vegetables (*cp.* this *J.*, 1917, 937).

Some theoretical aspects of electrical fume precipitation. Strong. *See* XI.

PATENTS.

Acids and other liquids; Vessels for containing.—W. Hayhurst, Accrington. Eng. Pat. 109,194, Jan. 6, 1917. (Appl. No. 310 of 1917.)

IN metal or other vessels lined with tiles, for containing acids, etc., the joints between the tiles are made with material capable of being vulcanised and are then vulcanised in position.

—W. H. C.

Sea-water evaporators for use on board ship. G. and J. Weir, Ltd., and J. G. Latta, Glasgow. Eng. Pat. 109,196, Jan. 15, 1917. (Appl. No. 705 of 1917.)

THE concentrated brine is discharged from the evaporator by an ejector actuated by a liquid, a valve being placed between the brine tank and the inlet to the ejector to enable the discharge of brine to be controlled.—W. H. C.

Fillers; Process for cleaning—in connection with the purification of sugar, oils, and chemicals. P. L. Wooster, Yonkers, N.Y. U.S. Pat. 1,240,290, Sep. 15, 1917. Date of appl. Aug. 17, 1916.

THE material clogging a deep filter bed is with-

drawn by vacuum from the lower portion, and the action is continued to withdraw the clogging material gradually from the upper portion of the bed through the previously treated lower portion.—J. H. P.

Filter. F. J. Sweetland, Montclair, N.J. U.S. Pat. 1,249,385, Sep. 18, 1917. Date of appl. May 9, 1914.

"METALLIC fibre" or "metallic wool" is woven into the filter cloth and extends across only a part of the sheet.—J. H. P.

Drying of hollow articles. E. Williams and W. H. Bunch, Birmingham. Eng. Pat. 109,715, Dec. 20, 1916. (Appl. No. 18,253 of 1916.)

In drying hollow articles which are closed at one end, the article, for example a projectile shell, is mounted with its mouth downwards on a support. A current of heated air is passed inside the shell by means of a pipe which extends nearly to the end of the shell.—J. H. P.

Dryer; Rotary — W. W. Swencel, Bloomburg, Pa. U.S. Pat. 1,240,386, Sep. 18, 1917. Date of appl. Oct. 12, 1916.

THE material to be dried passes through a number of inclined revolving drums, arranged one above another and enclosed in a housing. The drums communicate with a vertical conduit at one end and with a stack at the other. Hot air is drawn in at the top of the housing, circulates round the drums, leaves the housing at the bottom, and is then driven by a fan into the vertical conduit and through the drums to the stack.—J. H. P.

Concentrating liquids; Method and apparatus for — T. C. Oliver, Charlotte, N.C. U.S. Pat. 1,240,591, Sep. 18, 1917. Date of appl. Feb. 7, 1917.

THE liquid to be concentrated is sprayed down a tower and falls into a horizontal conduit or flue where it is agitated in a current of hot gases. The concentrated liquid passes out of the flue into another, situated at a lower level, where it is again agitated and any solid matter which may be deposited is removed. Means are provided for withdrawing waste gases and vapours from the tower.—J. H. P.

Air washing screen. W. N. and C. I. Haden, Trowbridge, Wilts. Eng. Pat. 109,213, Mar. 13, 1917. (Appl. No. 3660 of 1917.)

THE L-shaped laths of the screens between the ribs of which the air passes, have angular grooves or ribs with one side set at an angle of about 90° to the plane of the screen. Some or all of the L-shaped laths may have their two parts grooved on opposite sides, i.e., one on the outside and one on the inside.—W. H. C.

Centrifugal extractors; Safety mechanism for — W. Bartholomew, Assignor to Troy Laundry Machinery Co., Ltd., Chicago, Ill. U.S. Pat. 1,238,085, Aug. 28, 1917. Date of appl. Mar. 20, 1912.

THE casing of a centrifugal machine has a cover provided with a latch for locking it when closed. When the basket is rotating, the air current produced acts on a vane attached to an inclined oscillating rod on the casing and locks the latch, so that the cover cannot be opened while the drum is in motion. When the drum stops, the rod overbalances by gravity and unlocks the latch.—W. H. C.

Producing and condensing distillate; Apparatus for — G. Burton, Stapleton, Ala. U.S. Pat. 1,238,256, Aug. 28, 1917. Date of appl. Sept. 2, 1915.

THE condensing coil of a still has a pipe connection provided with a valve by means of which the cooling liquid in the condenser may be admitted to the interior of the coil.—W. H. C.

Licivator. J. M. Wilmer, Lancaster, Pa. U.S. Pat. 1,238,469, Aug. 28, 1917. Date of appl. May 5, 1916.

A SERIES of inclined pans are mounted step-wise and each is provided with a receiving basin in which is a rocking, grinding, and agitating cradle, means being provided for supplying compressed air to the cradle intermittently. The pans are also provided with perforated reciprocating, rubbing and scouring plates and are heated from below.—W. H. C.

Cooling apparatus. S. E. Seaman, Brooklyn, N.Y., Assignor to Seaman Waste Wood Chemical Co., Inc., New York. U.S. Pat. 1,240,609, Sep. 18, 1917. Date of appl. May 27, 1916.

A PIPE connecting a retort and cooling apparatus contains a valve which is held in position by a counter-weight. Excessive pressure from the retort opens the valve, and a seal is formed by the material passing through the pipe line, thus preventing any escape of gases.—J. H. P.

Condenser or cooler. A. E. L. Seanes, Ashton-upon-Mersey, Assignor to the British Westinghouse Electric and Manufacturing Co., Ltd., London. U.S. Pat. 1,238,574, Aug. 28, 1917. Date of appl. Nov. 26, 1915.

TO prevent corrosion a perforated plate is arranged in front of, parallel to, and spaced away from the tube-plate of a surface condenser, the perforations in the plate being opposite the ends of the tubes. The perforated plate is made of a metal which is electro-positive to the metal of the tubes, and plate and tubes are in metallic connection.—W. H. C.

Agglomerating finely-divided material; Method of — H. Redman, Edgewood, Pa., Assignor to The Redman Chemical Co. U.S. Pat. 1,239,221, Sep. 4, 1917. Date of appl. Sep. 5, 1916.

THE finely-divided material is agitated with suitable nuclei in a rotating grading device, the larger nodules or agglomerates are continuously removed, and a binding agent is continuously added to the smaller agglomerates.—W. F. F.

Separating solid matters from fluids or fluids from fluids; Apparatus for — F. E. Moss, Wigan. U.S. Pat. 1,240,081, Sept. 11, 1917. Date of appl. Feb. 15, 1917.

SEE Eng. Pat. 109,315 of 1916; this J., 1917, 1088.

Drying apparatus. G. H. and J. H. Stroband, Amsterdam, Netherlands. U.S. Pat. 1,241,299, Sept. 25, 1917. Date of appl. Apr. 5, 1916.

SEE Eng. Pat. 100,403 of 1916; this J., 1916, 1145.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Pyrites from coal; Recovery of — E. A. Holbrook, Univ. of Illinois Bull., Aug. 20, 1917. Eng. and Min. J., 1917, 104, 513—514.

IN experiments on Illinois coal containing 1—6%

of sulphur, mainly as pyrites, from 81 to 87% of the pyrites was recovered in marketable form. The hand-picked pyrites and washery refuse was crushed, screened, and concentrated by ordinary ore-dressing machinery, the concentrate obtained containing 40–47% S and the coal by-product about 8% S, partly in the form of pyrites.

—W. E. F. P.

Gas making: Substitutes for coal in —. J. des Usines à Gaz. Gas J., 1917, 140, 115.

VARIOUS substitutes for coal, and the methods of using them as applied in gas works in France and Switzerland, are described. At Geneva, sawdust is added to the extent of 10% to the normal charge of coal in Bueh vertical retorts. As an alternative, logs of wood, 3 ft. in length, are used, the charge then being 260 lb. as against 1240 lb. of coal. Wood and coal are worked alternately on two benches, with the result that the tars produced are not acid. The furnaces consume 25% more fuel than normally; the yield of gas is 8570 to 8830 cub. ft. per ton and the wood gas is not separated from the coal gas. At another Swiss works (La Chaux-de-Fonds, Neuchâtel) sawdust is carbonised in horizontal retorts, 375 lb. of sawdust being mixed with 60 lb. of coal, against a previous coal charge of 990 lb. The carbonising period in retorts of 14 ft. 8 in. is six hours. The calorific power of the gas is 4200 calories and the high proportion of water in the tar (30%) has given trouble. At Neuchâtel, wood is used to the extent of 28% of the coal. Horizontal retorts 9 ft. 6 in. in length are used, charges of 150 to 210 lb. being carbonised in 4 hrs., giving 10,600 cub. ft. of gas per ton of a calorific power averaging 4300 calories. The use of wood leads to the removal of carbon deposit and to a porous condition of the refractory, hence coal and wood are used alternately. Acid products from wood have caused some corrosion, and lime is required in purification. In France (Arcachon, Gironde) heath roots have been used, giving a yield of 23.78% of gas and 22.84% of charcoal. With a charge of 130 to 165 lb. the carbonising period is 2½ hours. The charcoal is superior to pine charcoal and the quality of the gas is satisfactory. At Royan (Charente Inférieure) a cargo of spoil flour has been used, giving 11,300 cub. ft. of gas and 1600 lb. of coke from 1 ton 7 cwt. of flour. The coke was of good quality with scarcely any ash.—J. E. C.

Gasoline from natural gas in the United States.

ACCORDING to statistics issued by the United States Geological Survey, the year 1916 was one of marked expansion in the natural-gas gasoline industry in the United States. The quantity of raw gasoline extracted from natural gas and sold in 1916 was 104,212,809 gals., valued at 14,408,201 dols., as compared with 65,364,665 gals. in 1915, valued at 5,150,823 dols. The volume of natural gas from which the 1916 output of gasoline was recovered is estimated at more than 208,800,000,000 cubic feet. The number of plants for extracting gasoline from natural gas in the United States increased from 414 at the beginning of 1916 to 594 at the end of the year, and the combined daily capacity of all plants increased from 232,336 galls. to 484,448 galls. in the year.

Note: U.S. gallon = 0.833 Imperial gallon.)

Lubricating oils: Method of testing [viscosity of] —. R. Dubrisay. Ann. Falsif., 1917, 10, 301–304.

THE viscosity of lubricating oils at different temperatures may be determined by means of a glass tube on which are blown two bulbs. Marks are made just above and below the upper bulb

and also above the lower bulb. The oil is drawn up into the tube, the top of the tube is closed by a piece of rubber tubing and a pinch-cock, and the apparatus is placed vertically in a water-bath of the desired temperature. When the oil has reached this temperature, the tube is raised until the water-level is at the mark above the lower bulb, the level of the oil is adjusted to the upper mark, and the pinch-cock is opened, the time required for the level of the oil to sink from the upper mark to the one below the top bulb being noted. If a sufficiently large water bath is employed, the difference in level due to the flow of oil from the tube is negligible. The change in fluidity of an oil with change of temperature is practically the same when measured by this method as it is when determined by the ordinary viscometers.—W. P. S.

Bitumens: Relations in composition of different forms of natural —. C. P. Mabery. J. Amer. Chem. Soc., 1917, 39, 2015–2027.

SAMPLES of bituminous (Deerfield) coal, gilsonite, and grahamite had the following proximate composition:—

	Gilsonite.	Grahamite.	Coal.
	%	%	%
Volatile matter	56.0	44.52	38.42
Fixed carbon	44.0	28.00	58.29
Ash	—	5.51	2.31
Sulphur	0.02	—	9.69
Nitrogen	1.05	2.7	0.05

The bituminous coal, when distilled *in vacuo* in an electrically heated iron still, yielded 5.6% of distillate, consisting largely of a number of hydrocarbons of the series C_nH_{2n-2} , which closely resembled those forming the larger part of the adjacent Mahone petroleum. No hydrocarbons of the series C_nH_{2n-2} were found in the coal distillates, but were present in the petroleum, whilst hydrocarbons of the series C_nH_{2n} , which are generally present in petroleum, although not in Mahone petroleum, were constituents of the coal distillates. The sample of gilsonite (from Utah) yielded from 50 to 56% of distillate containing hydrocarbons of the series C_nH_{2n} and C_nH_{2n-2} , which resembled the same hydrocarbons in petroleum, and also a series of unsaturated hydrocarbons, which readily absorbed oxygen and became of a dark colour. The deep colour of crude petroleum is probably due to absorption of oxygen by similar unsaturated hydrocarbons, such as nonylene found by Mabery and Quayle in Canadian petroleum. Most varieties of petroleum contain small proportions of these hydrocarbons, which have a peculiar odour, and can be readily extracted with sulphuric acid. The sample of grahamite resembled the bituminous coal in appearance. When distilled under reduced pressure of 20 mm. it yielded 13.5% of distillate with sp. gr. 0.85 at 20°C., which had an odour resembling that of petroleum distillates. It contained a series of hydrocarbons closely resembling those obtained from gilsonite, suggesting a common origin. The large proportion of nitrogen compounds present in gilsonite, however, indicates that it stands in closer relationship to petroleum than does grahamite, which only contains a trace of nitrogen bases.—C. A. M.

Toughness of bituminous aggregates. Reeve and Lewis. See 1X.

PATENTS.

Pulverised fuel: Employment of — in the furnaces of steam generators. J. G. Robinson, Manchester. Eng. Pat. 109,063, May 26, 1916. (Appl. No. 7516 of 1916.)

POWDERED fuel is conducted by worm conveyors

to nozzles and is blown thence into the furnace firebox by means of an air blast, the proportions of air and fuel being simultaneously controlled in synchronism with each other. Secondary air, induced by the chimney draught, is introduced into the furnace, and the products of combustion pass through small holes in the furnace crown to the water-jacketed portion of the boiler. Additional air may be admitted if necessary above the furnace crown, the products finally passing through the tubes of the boiler. Ignition openings are provided adjacent to the burner nozzles for starting up from the cold, being closed during normal operation. Normally the air blower and fuel conveyor are driven by steam from the boiler itself, but a secondary prime mover is provided for starting up or for abnormal conditions.—J. E. C.

Combustibles for domestic and industrial use. S. Fachini, Milan, Italy. Eng. Pat. 101,703, Sept. 14, 1916. (Appl. No. 13,072 of 1916.) Under Int. Conv., Oct. 2, 1915.

BONES freed from grease, gelatin, and moisture, and then saturated with liquid or liquefiable fuels, such as the residue of mineral oil, are burnt in a special receptacle, the liquid being added gradually and continuously.—J. E. C.

Coke ovens and other gas-heated furnaces; Method of introducing combustion gases into the heating flues of— D. and E. A. Bagley, Westminster. Eng. Pat. 109,752, Apr. 26, 1917. (Appl. No. 5920 of 1917.)

GAS is introduced into the heating flues of a coke oven by means of gas conduits impermeable to gases and composed of fused silica or vitreous porcelain, thus preventing the union of gas and air prior to their introduction to the heating flue. Cold air may be circulated round these conduits to maintain a temperature below 1200° C. The conduits are protected from direct radiation of heat from the heating flues by perforated caps, whilst packing devices connecting the conduits to the gas main allow movement through expansion.—J. E. C.

Gas generators or producers. Külnier Bros., Ltd., and F. W. Knowles, Dewsbury. Eng. Pat. 109,710, Dec. 11, 1916. (Appl. No. 17,772 of 1916.)

IN a gas producer, steam passes through flues or ducts round the periphery of the furnace doors and thence into a perforated steam-box passing across the furnace. The floor of the furnace slopes from front to back, and by means of two openings in the steam-box any surplus condensation water is conducted to the bottom of the steam-box, thus keeping the latter cool.—J. E. C.

Gas producers. E. A. W. Jefferies, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,240,220, Sept. 18, 1917. Date of appl., Jan. 2, 1913.

THE main section of a gas producer is rotated, whilst a fuel magazine concentric to this section remains stationary. The lower and forward end of the fuel magazine acts as a scraper to level the charge, the rear end being at a higher level, allowing a continuous feed of material into the producer. The height of the scraping edge is adjustable.

—J. E. C.

Hydraulic mains used in the manufacture of gas. Drakes, Ltd., and J. W. Drake, Halifax. Eng. Pat. 109,195, Jan. 8, 1917. (Appl. No. 338 of 1917.)

OVERFLOW connections and valves are fitted to a hydraulic main. In the event of the ordinary tar pipes becoming choked with tar or heavy

matter, these subsidiary overflow connections are brought into play by opening the necessary valves and closing valves on the normal tar outlet.—J. E. C.

Retort [; Gas —]. P. Plantinga, Cleveland, Ohio. U.S. Pat. 1,239,517, Sept. 11, 1917. Date of appl., Nov. 15, 1915.

AN inclined retort for coal distillation is provided with a stop plate, 7, pivoted at 5, so as to swing

outwards away from the mouthpiece of the retort. The plate is locked in its normal position by a pivoted lever, 9, engaging in a depression, 10.

—W. F. F.

Gas producers. C. B. Tully and O. E. Yeo, Westminster. Eng. Pat. 109,323, Sep. 26, 1916. (Appl. No. 13,687 of 1916.)

A GAS producer comprises a lower generating chamber, 1, and an upper fuel supply chamber, 5, of smaller sectional area and having relatively thin walls. Chambers, 17, between the outer

wall and the supply chamber, are filled with refractory material and may be used for the generation of steam or for the cracking of oil. Thus during the "blow," air is admitted at 3 and 14. Completely burnt products pass upwards through the passages, 33, 32, and 31, and the chamber, 17, leaving the producer by way of the

valve, 15a, whilst producer gas from the chamber, 1, is burnt by the air from 14, and the products of combustion heat the refractory material in 26, passing out through valve, 28. During the "run," water is admitted at 16, and oil at 29, the steam entering the bottom of the producer; the fixed oil vapours mingle with the water-gas, and the carburetted water-gas passes through the section, 5, and is delivered through the valve, 8.—J. E. C.

Tar, tar vapours, and the like: Apparatus for extracting — from illuminating or other gases. J. W. Scott, G. F. H. Beard, and R. and J. Dempster, Ltd., Manchester. Eng. Pat. 109,152, Nov. 9, 1916. (Appl. No. 16,058 of 1916.)

APPARATUS for extracting tar, tar vapours, and the like from gases, comprises two concentric vertical cylinders, the inner vessel being provided in its lower part with horizontal scrubbing devices in the form of baffles, and a spray. The flow of gas is retarded in the annular space between the cylinders by means of baffles, which may be set vertically or in the form of a spiral; when vertical baffles are used, they are arranged so that the gas follows a tortuous path through the annular space. A series of vertical perforated screens is inserted at the top of the inner vessel, and the temperature may be regulated by means of an enclosed coil, fixed in the lower part of the inner vessel. The gas is introduced at the bottom of the inner cylinder, rises to the top, where the tar particles are caught on the vertical screens, and passes through apertures in the wall of the cylinder to the annular space, finally leaving the apparatus through an outlet at the bottom of the outer cylinder.—J. E. C.

Liquefied gas; Apparatus for producing —. L. Wolf, Chicago, Ill. U.S. Pat. 1,240,397, Sept. 18, 1917. Date of appl., Dec. 3, 1913.

GASES containing hydrocarbon constituents are passed through a cooling chamber, where easily liquefiable constituents are deposited, and are then subjected to high compression and severe refrigeration to liquefy further constituents. A portion of the liquefied gas is conducted to the first cooling chamber where by expansion it serves to cool the main stream of gases.—J. E. C.

Gas purifier. C. E. Reese, Caney, Kans. U.S. Pat. 1,240,368, Sept. 18, 1917. Date of appl., Jan. 10, 1916.

A GAS purifier comprises a casing, and a pair of intercoiled spiral walls in the casing forming a passage way between them. On the outer walls of the passage way is a series of spaced vertical baffles consisting of flanges curved in horizontal section to form pockets and provided with perforations which are not in alignment in adjacent baffles.—J. E. C.

Mineral oils; Method of converting highly viscous —, or highly viscous residues from the distillation of mineral oils, into hydrocarbons of less viscosity. I. Rosenberg, Berlin. Eng. Pat. 109,572, Feb. 8, 1917. (Appl. No. 1912 of 1917.)

HIGHLY viscous mineral oils are heated to about 400° C. under a pressure of 4–6 atmos. (carefully avoiding higher pressure) for $\frac{1}{2}$ –2 hours. Inter-molecular re-arrangement of the oil is thus brought about, but, under the prescribed conditions, decomposition is avoided. The product has approximately the same boiling point and specific gravity as the untreated oil, but has a much lower viscosity; it can therefore serve as fuel, or can be treated for the preparation of lubricating oil.

For example, Californian crude oil having a viscosity of 116 at 20° and 12 at 50° C. (Engler) is heated at 400°–415° C. under a pressure of $4\frac{1}{2}$ –5 $\frac{1}{2}$ atmos. for $\frac{1}{2}$ hr. The product has a viscosity of 22 at 20° and 4 at 50° C., and flash point 115° C. A current of steam is then passed through the oil, heated to 150° C., until a test specimen has a flash point of 160° C.—L. A. C.

Hydrocarbon product. Liquid fuel. W. A. Hall. New York. U.S. Pats. 1,239,999 and 1,239,100, Sept. 4, 1917. Dates of appl., May 7 and May 6, 1915.

A LIQUID fuel for internal combustion engines produced from mineral oil, has a composition approximately of carbon 85.9%, hydrogen 12.76%, and contains ethylenic and aromatic hydrocarbons. The sp. gr. is not less than 0.76, and the boiling point ranges from 33° C. to 110° C. Not less than 23% of the fuel is volatile below 100° C. A larger fraction boils below 80° C. than that of a paraffin distillate with a similar sp. gr., and the fuel is slow burning, ignites quickly, but is not liable to pre-ignition. Before refining the fuel is yellow, possesses an odour, and leaves a dark non-drying substance on evaporation, but the colour and odour may be removed by distilling with, or filtering through, fullers' earth, which removes the colloidal resinous matter.—W. F. F.

Gasoline; Manufacture of —. A. D. Smith. Vinita, Okla., Assignor to J. T. Milliken, St. Louis, Mo. U.S. Pat. 1,239,423, Sept. 4, 1917. Date of appl., Apr. 28, 1915.

GAS oil or fuel oil of the paraffin series having a boiling point above 500° F. (260° C.) is cracked and distilled while circulating rapidly in a closed system of tubes and receptacles. The pressure is maintained at 125–150 lb. per sq. in. and the temperature at 600°–700° F. (315°–370° C.). The system is heated throughout, and deposition of carbon on the inclined heating surfaces is prevented by circulating the liquid by mechanical means over the surfaces towards their lower ends. The lighter hydrocarbons are removed and condensed, and the liquid in the lowest part of the system is periodically removed, filtered to remove carbon, and returned to the system together with fresh oil.—W. F. F.

Paraffin powder and process of making it. A. E. Nienstadt, Bensonhurst, N.Y. U.S. Pat. 1,239,618, Sep. 11, 1917. Date of appl., Feb. 3, 1916.

MELTED paraffin is mixed with from 3 to 5% of an alkali stearate, such as the ammonium salt, in aqueous solution, the mixture stirred till cool, and the water removed, leaving the mixture of paraffin and stearate as a fine powder.—B. V. S.

Paraffinum liquidum; Process of making —. H. V. Dunham, Bainbridge, N.Y., Assignor to Hall Motor Fuel, Ltd., London. U.S. Pat. 1,240,792, Sept. 18, 1917. Date of appl., Mar. 16, 1916.

CYLINDER oil is treated with a relatively large amount of sulphuric acid and the sludge removed. The residual oil is treated with a mixture of ammonia and alcohol and allowed to settle. The oil is then separated, dried, and filtered through a column of fullers' earth.—L. A. C.

Coal; Process of obtaining coke and by-product from —. H. P. Bostaph, and Bostaph Engineering Co., Detroit, Mich., U.S.A. Eng. Pat. 109,523, Oct. 30, 1916. (Appl. No. 15,178 of 1916.)

SEE U.S. Pat. 1,204,617 of 1916; this J., 1916, 1253.

II.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Heat; Process of producing — C. Ellis, Montclair, N.J., Assignor to Radiant Heating, Ltd., Leeds. U.S. Pat. 1,239,776, Sept. 11, 1917. Date of appl. Dec. 6, 1911. Renewed Feb. 9, 1917.

IN a surface combustion furnace in which a combustible gaseous mixture is injected and burnt within a bed of porous refractory material, the combustible gas and air are pre-heated and injected separately so that combustion takes place at the meeting point of the two currents. The position of the meeting point of the gas and air is a'justed according to their initial temperatures and the chemical characteristics of the gas.—W. F. F.

Electrode: Arc-lamp — W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,239,810, Sept. 11, 1917. Date of appl. Jan. 4, 1916.

AN arc-lamp electrode contains fluorides of rare earths, and precipitated barium sulphate and zinc sulphide (lithopone).—B. N.

III.—TAR AND TAR PRODUCTS.

PATENTS.

Sulphonic acids or their salts; Methods of producing — L. M. Dennis, Ithaca, N.Y., U.S.A. Eng. Pat. 109,709, Dec. 7, 1916. (Appl. No. 17,605 of 1916.)

SEE U.S. Pats. 1,211,923, 1,228,414, and 1,229,593 of 1917; this J., 1917, 208, 866.

Amino-[hydr]oxy-compounds; Manufacture of aromatic — A. Pignet, E. Steinbach, and R. Stocker, Basel, Assignor to Soc. Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,239,822, Sept. 11, 1917. Date of appl., Oct. 27, 1916.

SEE Eng. Pat. 18,081 of 1915; this J., 1917, 129.

IV.—COLOURING MATTERS AND DYES.

Colour of dyes; Effect of additional auxochromes on the — Part II. Triphenylmethane and azo dyes. P. C. Ghosh and E. R. Watson. Chem. Soc. Trans., 1917, 111, 815—829. (See this J., 1915, 1243; 1916, 685.)

THE investigation has been extended to the spectroscopic examination of some azo- and triphenylmethane dyes, and some phenylfluorone dyes have been prepared. The positions of the edges of the absorption bands in solutions of different concentration were observed with an ordinary spectroscope; it is considered preferable to use a spectrophotometer. The mechanism by which additional auxochromes affect the absorption spectra is not as yet understood, varying effects being produced which have not been explained. In some cases the multiplication of auxochromes produces the comparatively small effect of strengthening and broadening the absorption bands without much effect on their positions, e.g., in the azobenzene series, whereas in other cases the bands are shifted to a considerable extent but remain of about the same breadth. In other cases the breadth may be considerably increased or diminished, or additional bands may appear. Even in the same series very diverse effects may be produced.—F. W. A.

PATENTS.

Disazo dyestuffs and process of making same. R. Schüle, Frankfurt, Germany. U.S. Pat. 1,211,153, Sept. 25, 1917. Date of appl., Mar. 20, 1916.

SEE Eng. Pat. 28,925 of 1913; this J., 1915, 899. Green shades may also be obtained by treating the disazo dyestuffs on the fibre with diazotised p-nitroaniline.

Indoxyl and derivatives; Method of making — L. E. H. Cone, Assignor to The Dow Chemical Co., Midland, Mich. Reissue 14,361, Sept. 25, 1917, of U.S. Pat. 1,211,413, Jan. 9, 1917. Date of appl., June 18, 1917.

SEE this J., 1917, 211.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Flax; Art of retting — B. S. Summers, Port Huron, Mich. U.S. Pat. 1,238,359, Aug. 28, 1917. Date of appl., Aug. 25, 1913.

RAW flax is heated in a dilute solution of a weak alkali, thereby producing a dilute solution of organic acids in which another batch of flax is retted by digestion in a closed vessel under pressure.—J. F. B.

Cotton, wool, rags, etc.; Dryer for drying — A. Solod, Worcester, Mass. U.S. Pat. 1,238,589, Aug. 28, 1917. Date of appl., Feb. 28, 1917.

THE machine comprises a rotary cylinder mounted on rolls in an inclined position, carriers at either end to feed and discharge the material into and out of the cylinder, and a perforated pipe in one side of the cylinder, through which heated air is forced from a hot air chamber.—J. F. B.

Wool; Method of purifying raw — G. H. Benjamin, New York. U.S. Pat. 1,238,873, Sept. 4, 1917. Date of appl., May 4, 1916.

THE wool grease is removed by the successive solvent action of a heated oil, and of a mixture containing approximately 90% of benzol and 10% of carbon tetrachloride. The remaining impurities are removed by the action of transmitted air currents between 90° and 130° F. (33° and 51° C.) and with a moisture content between 25 and 75%.—B. N.

Artificial silk; Apparatus used in the manufacture of — J. Clayton, Coventry, Assignor to Courtaulds, Ltd., London. U.S. Pat. 1,240,075, Sept. 18, 1917. Date of appl., Apr. 18, 1916.

THE apparatus is provided with a spinning box and means for moving it up and down while spinning.—F. Sp.

Paper sizing apparatus. W. H. Sanburn, Springfield, Mass., Assignor to Strathmore Paper Co., Mittineague, Mass. U.S. Pat. 1,240,154, Sept. 11, 1917. Date of appl., Sept. 24, 1915.

IN connection with a sizing trough and squeeze-rolls a pair of immersion rolls spaced apart is provided, each roll being mounted independently of the other in such a way that they can be swung down into and up out of the trough and nearer to or further apart from each other, whereby the paper passing beneath the rolls can be immersed for varying lengths and at varying depths; the squeeze rolls are situated between the two immersion rolls.—J. F. B.

Pulp-beating engines. J. Nuttall, Bury, Eng. Pat. 109,558, Jan. 9, 1917. (Appl. No. 434 of 1917.)

Paper; Manufacture [sizing] of—. H. M. Wheelwright, Wheelwright, Mass., and J. Traquair, Ayer, Mass., U.S.A. Eng. Pat. 109,458, July 13, 1916. (Appl. No. 9389 of 1916.)

See U.S. Pat. 1,195,888 of 1916; this J., 1916, 1009.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Emulsions; Solvent properties of—. *Theory of dyeing in a "broken" soap bath.* P. Sisley. Bull. Soc. Chim., 1917, 24, 155—157.

THE concentration of colloids in a foam is shown to have a parallel in the concentration of colloids in the emulsified portion of an immiscible solvent. Suitable colloids are pure azo dyestuffs derived from the Safranines, e.g., the dyestuff obtained by the action of sodium naphtholate on the azo derivative of commercial Phenosafranine. On agitating a solution of 0.02 gm. of this dyestuff in a litre of water containing 2 c.c. of glacial acetic acid with chloroform, the dyestuff accumulates in the emulsified chloroform, leaving the aqueous solution practically decolorised; on allowing to stand until the emulsion is destroyed, the dyestuff concentrates in the aqueous layer just above the chloroform and then gradually diffuses into the acidulated water. This property of an emulsified liquid to dissolve much more than the normal liquid is used to explain a number of dyeing processes involving the use of emulsions in fixing very slightly soluble dyestuffs; e.g., the tri- and tetranitrodiphenylamines do not dye silk from aqueous suspension but dye from a "broken" soap bath. The use of oil emulsions in dyeing cotton and the dyeing of leather are further applications of this phenomenon, which may also be of value in explaining certain facts in physiology and therapy.—F. W. A.

PATENT.

Weighting of silk. N. A. Laury, Camden, N.J., Assignor to General Chemical Co., New York. U.S. Pat. 1,238,307, Aug. 28, 1917. Date of appl., Aug. 24, 1914.

SILK is weighted with an antimony compound by treating with an antimony alkali metal double chloride, a fixing agent, and a clarifying agent.—F. W. A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Recovery of pyrites from coal. Holbrook. See IIA.

- *Investigation of the wet thio-gen process for recovering sulphur from sulphur dioxide in smelter fumes.* Wells. See X.

PATENTS.

Lactic acid; Production of—. E. T. Olson, Ann Arbor, Assignor to Detroit Organic Chemical Co., Detroit, Mich. U.S. Pat. 1,240,766, Sep. 18, 1917. Date of appl., Oct. 19, 1916.

CRUDE lactic acid is treated with calcium hydroxide, the resulting lactate partially purified by separation and then treated in solution with

sulphuric acid. The mixture of calcium sulphate and lactic acid is dried and heated to 130° C. with the formation of lactide and lactic anhydride. After removal of soluble impurities pure lactic acid is obtained by hydrolysis in steam.—B. V. S.

Magnesia; Process of making—. L. Jesser, Vienna. U.S. Pat. 1,238,147, Aug. 28, 1917. Date of appl., Nov. 7, 1916.

MAGNESIUM carbonate is subjected in a revolving furnace to the action of burning gases at a temperature not higher than necessary for the effective removal of the carbon dioxide. Additional agitation is provided for. The temperature is regulated by the addition of air and steam to the burning gases, which are supplied to the furnace from a chamber in front of it.—H. J. II.

Alkalis; Process of producing— from kelp. H. L. Trumbull, Seattle, Wash. U.S. Pat. 1,228,600, Aug. 28, 1917. Date of appl., Mar. 22, 1917.

KELP is subjected to electrolytic or electro-osmotic action in a divided cell with a mercury cathode. The alkali amalgam produced is treated with water and the resulting alkali solution evaporated to yield an alkaline product containing caustic potash.—H. J. II.

Metal-hydroxide solutions; Process of making—. C. P. Hoover, Columbus, Ohio. U.S. Pat. 1,238,916, Sep. 4, 1917. Date of appl., Apr. 24, 1917.

SODIUM hydroxide solution is produced by passing a solution of another hydroxide, e.g., that of calcium, through a sodium-zeolite filter until the latter becomes practically inactive through loss of sodium. The exhausted zeolite is regenerated by washing it with a solution of sodium chloride, and the filter is then used again for the production of sodium hydroxide.—B. N.

Ammonia; Process of oxidising— and catalytic bodies therefor. C. L. Parsons, Washington, D.C. U.S. Pat. 1,239,125, Sept. 4, 1917. Date of appl., Apr. 20, 1917. (Dedicated to the public.)

NITROGEN oxides are produced by passing a mixture of ammonia and a gas containing oxygen over a heated composite material, comprising a catalyst, such as lead chromate, and a carrier which is not substantially affected by the lead chromate at 1000° C. e.g., bone ash.—B. N.

Alunite; Method of treating—. F. K. Cameron and J. A. Cullen, Washington, D.C. U.S. Pat. 1,239,768, Sep. 11, 1917. Date of appl., Nov. 11, 1916.

ALUNITE is treated with sufficient strong sulphuric acid to neutralise the basic compound, with formation of a cake which is largely soluble in water and from which alum and aluminium sulphate are obtained by solution and crystallisation.—B. V. S.

Felspar, felspathic rock, and similar material; Process for treating—. W. Glaeser, Brooklyn, N.Y., Assignor to G. T. Bishop, Macedonia, Ohio. U.S. Pat. 1,239,787, Sep. 11, 1917. Date of appl., Sep. 16, 1914.

FELSPAR or similar material is heated to a low red heat, suddenly cooled, mixed with anhydrous calcium chloride, and the mixture fused in presence of air at a temperature between 1200° and 1800° C.—B. V. S.

Alumina [and ferrosilicon and alkali compounds]: Manufacture of crystalline fused—F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,230,984, Sep. 11, 1917. Date of appl. Feb. 26, 1916.

ORES containing alumina and a substantial amount of alkali compounds are heated electrically so as to volatilise the alkali, fuse the alumina, and reduce any excess of silica and iron oxide present to ferrosilicon. The alkali is recovered by condensing the fumes from the furnace.—A. B. S.

Carbon dioxide and sodium sulphate: Making—W. T. Mackey and J. S. Carroll, Dublin, Eng. Pat. 109,511, Oct. 11, 1916. (Appl. No. 14,128 of 1916.)

A GRANULATED mixture of saltcake (240 parts) and calcium carbonate, preferably whiting (about 160 parts, according to the acidity of the saltcake), is treated with cold or warm water, or with carbon dioxide saturated with moisture where a dry residue is desired. Carbon dioxide is evolved and sodium calcium sulphate left. This may be used in the manufacture of glass or as a flux in the extraction of metals, or the sodium sulphate may be extracted. A suitable apparatus for the treatment of the saltcake and whiting mixture is described.—B. V. S.

Aluminate: Production of—from alunit. P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago, Ill. U.S. Pat. 1,240,570, Sep. 18, 1917. Date of appl. Oct. 21, 1916.

POTASSIUM aluminate, $K_2O \cdot 2Al_2O_3$, is produced by heating a mixture of alunit and calcium oxide to 1000° C. in the presence of steam and extracting the resulting mass with water.—B. V. S.

Barium aluminat and sulphur: Manufacture of—P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago, Ill. U.S. Pat. 1,240,571, Sep. 18, 1917. Date of appl. Oct. 21, 1916.

BARIUM aluminat is produced by heating a mixture of a reducible barium compound, alumina, and carbon, in an atmosphere of reducing gas, or of reducing gas and steam. In the latter case, if barium sulphate is used, sulphur also is produced.—B. V. S.

Barium aluminat: Production of—P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago, Ill. U.S. Pat. 1,240,572, Sep. 18, 1917. Date of appl. Oct. 21, 1916.

A REDUCIBLE barium compound, such as the sulphate, is heated with aluminium oxide in the presence of calcium oxide and steam.—B. V. S.

Kelp: Process for incinerating—G. A. Lamb, Los Angeles, Cal. U.S. Pat. 1,240,737, Sep. 18, 1917. Date of appl. Nov. 3, 1915; renewed Feb. 8, 1917.

KELP is continuously passed through a combustion chamber in which liquid or gaseous fuel is burnt in oxygen, both being supplied at intervals along the length of the chamber. The ash is continuously separated during passage of the kelp along the combustion chamber, the unburnt portion being passed on. Any unburnt kelp passing through the first combustion chamber is further treated in an auxiliary chamber in which also the ash may be further treated.—B. V. S.

Ceramic acid gas: Method of removing—from nitrogen gas. H. Philipp, Perth Amboy, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,239,546, Sep. 11, 1917. Date of appl. June 30, 1914.

THE mixed gases are passed through milk of lime containing a small quantity of an alkali hydroxide, e.g. sodium hydroxide.—B. V. S.

Graphitic carbon from graphite scale: Method of recovering—F. W. Weissmann, Assignor to The Hill and Griffith Co., Cincinnati, Ohio. U.S. Pat. 1,239,992, Sep. 11, 1917. Date of appl. Apr. 28, 1916.

Dry artificial graphitic scale is screened, subjected to the action of an air separator, bolted, and treated in an electromagnetic separator. The resulting graphite is further purified by powdering, levigating, boiling with acid, washing, pressing, and drying.—B. V. S.

Vessels for containing acids and other liquids. Eng. Pat. 109,194. See I.

Recovering alkalis from cement materials. U.S. Pat. 1,239,610. See IX.

Process of making lampblack and hydrochloric acid. U.S. Pat. 1,238,734. See XIII.

VIII.—GLASS; CERAMICS.

Refractories and modern kilns. J. G. Maxwell. Ceramic Soc. (Refractory Materials Section), Glasgow, Oct. 2, 1917.

THE author details the advantages of gaseous fuel over solid fuel for firing kilns, and gives the preference to producer gas for the following reasons: Temperature is under complete control. High temperatures can be obtained more economically and speedily than with coal, and any given temperature reached is more easily maintained in the kiln than with coal, and with comparatively little fluctuation. There is great saving on wear and tear of kiln, and great cleanliness of burning if an adequate supply of air is provided. The three best known types of kiln for refractory goods are: the continuous annular, gas-fired kiln; the continuous annular, chamber type, gas-fired kiln; the continuous tunnel and car kiln. The author considers that the tunnel type is by far the best, and he believes it will be the kiln of the future for most kinds of high-class refractory ware on account of the ease of working, the low cost of handling the material, low fuel consumption, and large output, combined with small amount of structural work.—A. B. S.

Refractory materials: The testing of—J. W. Mellor. Ceramic Soc. (Refractory Materials Section), Glasgow, Oct. 2, 1917.

THE ultimate object in testing a firebrick is to determine how it will behave when in use, so that tests should as nearly as possible reproduce service conditions. A service trial is the ideal mode of testing, but usually requires too long a time and even then is not always consistent. The fire-stability of a refractory material as shown by the squatting temperature is perhaps its most important quality. In making this test, it is important to specify the rate at which the sample is heated, as the faster the rise in temperature the greater the difference between the true and apparent squatting temperature. The best results

are obtained with pieces of material shaped like Seger cones, $1\frac{1}{2}$ in. high and $\frac{1}{2}$ — $\frac{3}{4}$ in. base, Seger cones being placed close to the samples and heated at the same time. The results should be reported in "cones" rather than in degrees of temperature. Larger test pieces are not advantageous, as the first signs of fusion are connected with the surface tension. The atmosphere in which the samples are heated should be as nearly neutral as possible, though so many firebricks are used in a reducing atmosphere that it is sometimes desirable to use this in testing them; in this case, however, it is difficult to obtain constant results on account of variations in the rate at which the iron compounds present in the material are reduced. When refractory materials are heated under a load of (say) 30—50 lb. per sq. in. the results vary with the nature of the bricks. Aluminous bricks show a much lower squatting temperature and there is every reason to suppose that they could be vitrified by pressure alone. W. Spring has shown that pure alumina can be melted at ordinary temperature under a pressure of 5000 atmos. per sq. cm. Hence, it is logical to suppose that fire-clay bricks could be made without burning if the pressure were sufficiently great.

Refractory materials, when heated under a load, appear to contradict the well-known thermodynamic formula:—

$$\frac{dT}{dP} = \frac{T}{L} (v - v_0)$$

where P=pressure, T=absolute temperature of fusion, L=latent heat of fusion, v =volume after fusion, and v_0 =volume before fusion. Hence, if L is constant an increase in pressure should raise, not lower, the fusion point. The author considers the discrepancy is due to the formula not being applicable to bricks as the distribution of the pressure is not uniform in all directions.—A. B. S.

PATENTS.

Glass tank-furnace. W. G. Bergman, Assignor to The Toledo Glass Co., Toledo, Ohio. U.S. Pat. 1,237,282, Aug. 21, 1917. Date of appl., May 4, 1914.

THE combustion chamber of the furnace is built above the glass tank but independent of it and carried by a suitable system of iron work. The walls of the furnace are substantially flush with those of the tank but separated from them by a space which is closed by adjustable blocks of reverse wedge shape.—H. J. H.

Glass-tank. W. G. Bergman, Assignor to The Toledo Glass Co., Toledo, Ohio. U.S. Pat. 1,237,283, Oct. 21, 1917. Date of appl., June 4, 1914.

THE combustion chamber is supported over and independently of the glass tank by a suitable system of iron work. The tank is a little larger than the combustion chamber, the lowest course of which dips into the glass bath, thus leaving a margin of glass exposed to the air. The blocks of the lowest or sealing course are detachable and suspended by iron brackets from the abutment blocks supporting the arch of the furnace.—H. J. H.

Glass [tanks] and other reverberatory furnaces; Mean for heating. — The Tyne Glass Works, Ltd., Gateshead, and A. B. Roxburgh, Monk-seaton. Eng. Pat. 109,541, Nov. 24, 1916. (Appl. No. 16,865 of 1916.)

THE furnace is heated by producer gas which has previously been passed through a scrubber or filter to remove dust, etc. The gas is taken from the producer at a point below the top of the fuel-bed and is led through a dust-trap into the furnace. Hot air is supplied to the furnace through a flue,

and is heated by conduction from the furnace and from the waste heat flues. A flap-valve in the passage is normally closed but opens automatically if the back pressure in the dust chamber becomes excessive, as during back-firing or explosions.

—A. B. S.

Plate glass; Process of and apparatus for the manufacture of. — J. H. McKelvey, Kirkwood, Mo., and C. F. Ryan, St. Louis, Mo., U.S.A. Eng. Pat. 109,631, Aug. 15, 1916. (Appl. No. 11,525 of 1916.)

THE constituents are melted in a continuous melting tank, a portion of the metal being transferred to a second tank heated independently, where it is reheated and afterwards poured on to the casting table in the usual manner. The second tank, or conditioning chamber, is stationary except for a shallow collection receptacle in the base of the tank, which can be tilted to deposit the charge on the rolling table. In this way, the advantages of the usual method for making sheet glass are made available for the production of plate glass without the drawbacks experienced when the molten metal is ladled out previous to casting.

—A. B. S.

Cylindrical and tubular glass articles; Manufacture of. — D. Webb, Manchester. Eng. Pat. 109,711, Dec. 13, 1916. (Appl. No. 17,899 of 1916.)

THE closed end of a hollow ball or billet of glass blown in the customary manner, is opened and a tubular drawing iron attached, a current of compressed air being meanwhile passed through the tube so as to cool the interior as rapidly as the exterior of the article and thus produce a harder internal surface with small liability to fracture when exposed to changing temperatures.

—A. B. S.

Glass-drawing apparatus; Continuous. — R. G. Ewing, Toledo, Ohio. U.S. Pat. 1,240,185, Sept. 18, 1917. Date of appl., Apr. 9, 1917.

A CONTINUOUS glass-drawing apparatus (see fig.) comprises a continuous melting tank delivering a continuous supply of "metal" to a rotary

drawing supply tank, a stationary hood which forms a heating chamber above the drawing tank, means to keep part of the molten "metal" motionless during the drawing operation, and means to draw the glass continuously whilst it is in a suitable condition and free from any detrimental deposits.

—A. B. S.

Refractories; Production of. — P. R. Hershman, Chicago, Assignor to The Mineral Products Co., New York. U.S. Pat. 1,240,569, Sept. 18, 1917. Date of appl., July 19, 1915.

A MOULDED mixture of a refractory metallic oxide, such as alumina, with carbon and a binding agent is raised to a high temperature in a non-oxidising atmosphere. The binding agent acts as a cement until the particle of the mass begin to frit together, and is finally driven off. The proportion of carbon is arranged so that shrinkage and increase of density will result in the heating process.—B. V. S.

Abrasive composition containing alumina and zirconia. Aluminium abrasive and method of preparing the same. L. E. Saunders and R. H. White, Niagara Falls, N.Y., Assignors to Norton Co., Worcester, Mass. U.S. Pats. (A) 1,240,490 and (B) 1,240,491, Sept. 18, 1917. Date of appl. Feb. 12, 1917.

AN abrasive material made in an electric furnace consists of (A) crystalline grains composed chiefly of alumina and zirconia, with a ceramic bond; (B) grains containing crystalline alumina together with zirconia, silica, titanium oxide, and iron oxide, these grains being united by a ceramic bond. —A. B. S.

Bricks; Process of burning——. F. B. Lambert, Assignor to Lambert Process Co., Chicago. Ill. U.S. Pat. 1,239,189, Sept. 4, 1917. Date of appl., Mar. 20, 1915.

THE kiln is fitted with an internal forced-draught furnace which is heated in such a manner that any water present in the bricks is evaporated faster than it can escape from the kiln and therefore forms a damper of steam between the heat-zone and the outlet for the products of combustion. The firing is arranged to produce a zone of incandescence at right angles to the general travel of the products of combustion through the kiln, and the blanket or damper of steam lies above the zone of incandescence. The invention is described with particular reference to an up-draught oil-fired kiln, the burners being placed near the base and the lowest courses of bricks to be burned being first raised to the finishing temperature.—A. B. S.

Enamels or glazes; Process of producing well clouded—by means of substitutes for stannic oxide. H. Kretzer, Wallersheim, and A. Cappel, Coblenz, Germany, U.S. Pat. 1,239,112, Sep. 4, 1917. Date of appl., Sep. 9, 1914.

IN the manufacture of white clouded enamels or glazes, the opacifier, if a material other than stannic oxide, is added to the wet-mill towards the end of the grinding of the other ingredients, together with such substances (electrolytes) as will prevent its transformation into a colloidal form or will precipitate any colloid which may be produced.—A. B. S.

Glass blowing apparatus. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 109,544, Dec. 5, 1916. (Appl. No. 17,464 of 1916.)

IX.—BUILDING MATERIALS.

Cement; Effect of sulphide on——. J. C. Witt. Philippine J. Sci., 1916. 11 A, 273—288.

THE author has investigated the basis of the widely held view that sulphur compounds have a deleterious action on cement. Five different typical brands of cement were subjected to trial in mixings containing sodium sulphide solutions of varying concentration. Experiments were made on the neat cements and on mixtures of cement and sand, and the physical properties of the products were determined. The results showed that sodium sulphide modifies greatly the setting time of a cement, with low concentration retarding the set, with high concentration accelerating it. Cements high in iron are specially sensitive. There is a marked decrease in the tensile strength, varying with the sulphide con-

centration and the iron content of the cement. A green coloration is produced. It is probable that the sulphide and iron oxide react to form a colloid which forms inert films in the mass, interfering with the cohesion. The colloid also removes some calcium hydroxide from solution and this also leads to reduced strength.—H. J. H.

Bituminous aggregates; Toughness of——. C. S. Reeve and R. H. Lewis. J. Agric. Res., 1917, 10, 349—350.

BITUMINOUS-CONCRETE roads in New England, in which the rock used was trap-rock or quartzite, the binder being a coal-tar product, were found to fail very rapidly compared with roads in which the rock used was a field-stone of granitic or gneissoid character, and compared also with roads in Jamaica, N.Y., in which trap-rock was used. The authors find that the difference in behaviour of the various types of rock cannot be directly attributed to any of the ordinary physical properties—such as hardness, toughness, specific gravity, etc., but that it appears to be largely due to differences in the surface character of the rock particles: the glassy surfaces of some rock particles fail to "hold" the bitumen as well as the rougher surfaces of others. They find also that whilst relatively soft or fluid bitumens may yield satisfactory results with some types of rock, their use with other types will lead to failure of the road surface. Laboratory tests can be directly correlated with the results obtained in actual service, and by means of the impact or toughness test of the aggregates, it may be possible to determine in advance their relative behaviour in actual service.—E. W. L.

PATENTS.

Slaking times and cements; Methods of and means for——. C. Candlot, Paris. Eng. Pat. 109,391, Feb. 27, 1917. (Appl. No. 2867 of 1917.)

IN the slaking of calcined lime and cements the use of an excess of water may lead to hydration of silicates and aluminates and consequent deterioration of the products. This is avoided by the use of a slaking machine having automatic arrangements for controlling the feed of calcined material and water and the removal of the slaked product. The calcined material falls into a vessel revolving about a vertical shaft. It is slaked by water delivered through orifices in a pipe arranged radially, and as the slaked material is at once covered by a fresh layer of material the heat produced in the reaction is conserved. The slaked material is discharged from the machine through a gap between the sides and the base, by self-adjusting blades which ensure the maintenance of a constant level in the apparatus. —H. J. H.

Hydrating lime; Process of——. W. E. Carson. Riverdon, Va. U.S. Pat. 1,239,256, Sept. 4, 1917. Date of appl., Dec. 15, 1916.

A HIGHLY plastic, dry hydrated lime is made by slaking two different portions of lime in the same manner, but with different proportions of water, and then mixing the products. The slaking may be effected by mixing the ground lime with water and storing it for at least 8 hours in a tall columnar chamber.—A. B. S.

Rotary [cement] furnace structure. B. E. Eldred, Assignor to Commercial Research Co., New York. U.S. Pat. 1,238,394, Aug. 28, 1917. Date of appl., June 18, 1913.

A ROTARY cement furnace is constructed with a

cylindrical revolving steel shell lined with refractory material and having a fan mounted on and forming part of the furnace body. Longitudinal channels are arranged in the refractory lining through which the fan drives a current of air, which is thus preheated and then fed into the furnace with the fuel at the firing end.—H. J. H.

White cement. W. C. Ewing, Los Angeles, Cal. U.S. Pat. 1,239,579, Sep. 11, 1917. Date of appl., June 29, 1916.

A WHITE cement is made by mixing 20 parts of commercial Portland cement with 1 part of silica (diatomaceous earth) and 1 part of calcium hydroxide.—A. B. S.

Alkalis from cement materials; Recovering——S. B. Newberry, Baybridge, Ohio. U.S. Pat. 1,239,616, Sep. 11, 1917. Date of appl., Apr. 11, 1916.

THE dust collected from rotary cement kilns is re-burned in a vertical kiln with a strong blast of air under 5–20 lb. pressure. The gases evolved are cooled and the alkalis therein are obtained in a soluble form.—A. B. S.

Basic brick. H. A. Kennedy, Clearfield, Pa. U.S. Pat. 1,240,148, Sep. 11, 1917. Date of appl., July 26, 1917.

PARTICLES containing lime and magnesia 78–92, and silica 2–13%, are mixed with a fluxing agent and the mixture is moulded and fritted so as to produce refractory basic bricks with a vitrified outer surface.—A. B. S.

[Paving material] plastics; Manufacture of——*Plastic composition and method of making the same.* (A) M. A. Popkess, Kansas City, Mo., Assignor to Bituminized Road Co. (B) M. A. Popkess, New York. U.S. Pats. (A) 1,240,252, and (B) 1,240,253, Sept. 18, 1917. Dates of appl., Apr. 11 and Dec. 13, 1916.

(A) A PAVING material is made by heating a moist, finely divided, earthy material to a temperature below 212° F. (100° C.) to vaporise part of the moisture. Liquid bitumen is then added, the mixture stirred to disintegrate it and impregnate the earthy material with bitumen, and the temperature then raised above 212° F. to expel the moisture. (B) A paving composition is made by producing an emulsion of asphalt, liquid at ordinary temperatures, with water and clayey material. The amount of asphalt is such as to give a dense, hard, and malleable composition, and the amount of water is such that the product can be easily worked during mixing. The mixture is agitated and disintegrated till it is reduced to fine particles, and the water is then removed.—W. F. F.

Porous blocks; Methods of treating [impregnating]——C. E. Fuller, Kansas City, Mo., U.S.A. Eng. Pat. 101,792, Sept. 12, 1916. (Appl. 12,921 of 1916.) Under Int. Conv., Oct. 9, 1915. SEE U.S. Pat. 1,176,281 of 1916; this J., 1916, 542.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Tantalum in alloy steels; Determination of——G. L. Kelley, F. B. Myers, and C. B. Hingworth. J. Ind. Eng. Chem., 1917, 9, 852–854.

In the absence of tungsten:—1 gm. (for 2 to 5% tantalum steels), 2 grms. (for 0.5 to 2% steels), or up to 10 grms. for lower proportions, is dissolved in hydrochloric acid (1:1), the solution evaporated to dryness, the residue boiled with dilute hydrochloric acid, and the solution filtered. The

filtrate is concentrated to a syrup, nitric acid being added during the evaporation, to oxidise the iron, and the residue is treated with 50 c.c. of strong hydrochloric acid and again evaporated. After cooling, the iron is extracted by means of ether, and the aqueous layer boiled to remove dissolved ether, and treated with ammonia in slight excess, to precipitate the tantalum. If chromium or vanadium are present in appreciable quantity, the solution is evaporated with 15 c.c. of sulphuric acid (sp. gr. 1.58) until fumes appear and is then made up to 200 c.c. with water, and boiled with 20 c.c. of 6–1% silver nitrate solution and 3 grms. of ammonium persulphate, to oxidise the chromium and vanadium to chromate and vanadate. A slight excess of ammonia is then added, and the solution again boiled. The precipitate, which will contain all the tantalum and aluminium, is washed, and added to the precipitate obtained in the first filtration, and the united precipitates ignited in a platinum crucible at a moderate temperature, and then fused with 2 to 5 grms. of fused potassium bisulphate. The melt is treated with hot dilute (1:1) hydrochloric acid, the liquid filtered, and the residue of silica and tantalum oxide (Ta_2O_5), is treated with a few drops of sulphuric acid and 2 to 5 c.c. of hydrofluoric acid in a platinum crucible, the acid evaporated, and the residue weighed as Ta_2O_5 .

In presence of tungsten:—The hot solution in hydrochloric acid, obtained as above, is oxidised by the addition of nitric acid, drop by drop, and then diluted with 4 vols. of water, and boiled for a few mins. The insoluble tungstic oxide is filtered off, and washed with water acidified with hydrochloric acid, and the filtrate and washings evaporated to a syrup, which is treated with 50 c.c. of strong hydrochloric acid and again evaporated, and the ferric iron extracted with ether, as described. The precipitate of tungstic oxide is treated with dilute ammonia solution to dissolve tungsten compounds, and the residue, which may contain tantalum and traces of iron, tungsten, chromium, etc., is reserved. The aqueous layer from the ether extraction is boiled, evaporated with sulphuric acid, and treated with silver nitrate and ammonium persulphate, as above. Ammonia will then precipitate an impure hydrated tantallic oxide, leaving most of the chromium and vanadium in solution. From this point the process is the same as in the absence of tungsten, except that the final residue from the fusion with potassium bisulphate may contain a little tungstic oxide. It should therefore be treated with dilute ammonia solution and washed with water prior to ignition with hydrofluoric acid and sulphuric acid to remove the silica.—C. A. M.

Zinc burning as a metallurgical process. W. R. Ingalls. Bull. Amer. Inst. Min. Eng., Sept., 1917. Eng. and Min. J., 1917, 104, 457–461.

THE Wetherill process for the manufacture of zinc oxide and zinc-lead pigments directly from the ore consists in heating the ore with carbonaceous fuel, the metallic vapour being at once burned to oxide by the furnace gases. This process can also be used for the igneous concentration of zinc ores; it can be carried out in blast smelting-furnaces, the gangue being slagged off and other minerals reduced to matte or metal. The smelting column in the blast furnaces at Canyon City, Colo., is only 18 in. high, to prevent the formation of accretions. Some iron blast furnaces in Virginia and the spiegel-eisen furnaces of the New Jersey Zinc Co. afford examples of zinc burning as an incidental operation in blast-furnace smelting. The reverberatory furnace is better adapted for the work, as no accretions are formed; at Anaconda, the residues from the leaching for electrolytic zinc extraction are thus worked up. In the Wetherill process a grate-furnace is used, there being no run

of slag. In using the method for concentrating zinc, no attention need be paid to the colour of the resulting fume as in pigment-making; hence the process is very simple, and low-grade ores would be made available. In the electrolytic leaching process, it may be found more economical to burn the ore on grates and leach the product obtained by condensing the fume. Lead is even more easily burned off than zinc. The choice between a smelting or grate furnace would depend on the nature of the ore: if copper and silver are present, a smelting furnace would be adopted. In such a case the slag would have to be very silicious so as to maintain a low zinc slag-loss (i.e., little over 3%).—W. R. S.

Tin and tungsten; Separation of—*in tin-bearing tungsten ores.* Travers. *Comptes rend.* 1917, 165, 108—110.

The very finely ground ore is fused with anhydrous sodium sulphate at a bright red heat in a porcelain crucible, the melt treated with boiling water and diluted to 700—800 c.c., and the solution treated with a small excess of sulphuric acid. The precipitated stannous sulphide is purified by solution in yellow ammonium sulphide, re-precipitated, and ignited to stannic oxide. Tungsten is determined by fusing another portion in a similar manner and decomposing the melt directly with strong *aqua regia*; if titanium is also to be determined, sulphuric acid is used. The bulk of the tungstic acid separates, mixed with silica. The filtrate is treated with ammonia in quantity insufficient to dissolve tungstic acid: the ferric hydroxide precipitate containing the balance of the tungstic acid is washed free from sodium salts and dissolved in hydrochloric acid (1:1). The solution is evaporated to dryness to remove the tungstic acid insoluble, and the latter is separated from silica by the usual method.—W. R. S.

Nickel and zirconium; Analysis of alloys of—*G. L. Kelley and F. B. Myers. J. Ind. Eng. Chem.* 1917, 9, 851.

ONE gram. of the finely divided sample is dissolved in a mixture of 40 c.c. of hydrochloric acid and 20 c.c. of nitric acid, and the solution evaporated with 20 c.c. of sulphuric acid until white fumes appear. On diluting the liquid with water nearly all the tungsten separates as tungstic oxide together with the silica, whilst practically the whole of the zirconium will be found in the filtrate. The precipitate is ignited in a platinum crucible and weighed (SiO_2 , WO_3 , and impurities), then treated with hydrofluoric and sulphuric acids to remove silica (determined by loss in weight), and subsequently fused with sodium carbonate, and extracted with water. Any residue is deducted

from the weight of impure tungstic oxide left in the crucible after removal of the silica. The solution, containing the iron, nickel, aluminium, and zirconium, is made up to a definite volume, and half is taken for the determination of the iron, by precipitation with ammonia, solution of the precipitate in sulphuric acid, addition of an excess of 10 c.c. of acid (sp. gr. 1.58), reduction of the solution, and titration of the iron with standard permanganate solution. The other half of the solution is treated with ammonia in excess, and the nickel removed electrolytically, and, after removal of iron and aluminium if necessary, determined electrolytically or by precipitation with dimethylglyoxime. The solution containing aluminium, iron, and zirconium is boiled to remove most of the ammonia, and allowed to stand, the precipitate separated, washed with water, and dissolved in the smallest possible amount of hydrochloric acid, and the solution treated with an excess of solid potassium hydroxide, to precipitate iron and zirconium, boiled for 1 min., allowed to stand, and filtered. The filtrate is acidified with hydrochloric acid, and then made faintly alkaline with ammonia, boiled, and filtered, and the precipitate washed and dissolved in hydrochloric acid. The solution is evaporated with 7 to 10 c.c. of sulphuric acid (sp. gr. 1.58), until white fumes appear, then diluted, filtered from silica, and the aluminium precipitated with ammonia. The precipitate of iron and zirconium hydroxides is dissolved in dilute (1:1) hydrochloric acid and reprecipitated with ammonia from the boiling solution. The ignited precipitate consists of Fe_2O_3 and ZrO_2 , and its weight, less the amount of iron (as Fe_2O_3) found by titration, gives the amount of zirconia. If a determination of manganese is required, 1.5 gm. of the alloy is taken, and a third of the filtrate from the tungstic oxide is treated with ammonia and ammonium persulphate, before boiling. The precipitate is washed, dissolved in nitric acid, with the addition of a little sodium sulphite or hydrogen peroxide to aid solution, and the manganese oxidised by means of sodium bismuthate, and determined by one of the usual methods.

—C. A. M.

Metals of high boiling point; Vapour pressure and volatility of several—*J. Johnston. J. Ind. Eng. Chem.* 1917, 9, 873—878.

THE various published data on the vapour pressure and volatility of metals have been collated, and formulae have been worked out for calculating the vapour pressure at any temperature. The following table gives the approximate boiling points of the principal metals at various pressures, the figures for those in italics having been calculated from a single observation:—

Metal.	Melting point	p in m.m. of mercury.							
		10 ⁻²	10 ⁻¹	1	10	50	100	760	
	° C.	° C.	° C.	° C.	° C.	° C.	° C.	° C.	° C.
Cadmium	321	220	270	330	410	500	590	630	740

Sulphur from sulphur dioxide in smelter gases; Investigation of the wet "thiogen" process for recovering—A. E. Wells, U.S. Bureau of Mines Tech. Paper 133. J. Ind. Eng. Chem., 1917, 9, 872—873.

THE wet "thiogen" process for recovering sulphur from sulphur dioxide in smelter gases is based upon the fact that barium sulphide suspended in water reacts with sulphur dioxide in accordance with the equation:

The gases are cooled, freed from dust, and passed through an absorption tower, in which the sulphur dioxide is absorbed by water. This solution is treated with powdered barium sulphide, the precipitate of barium sulphite, thiosulphate, and sulphur is allowed to settle and then filtered off and dried, whilst the mother liquor is returned to the absorption tower. The free sulphur and half of the sulphur from the thiosulphate is distilled, and the sulphur vapour condensed, whilst the residual barium sulphite or sulphate

in canvas filters with the aid of a vacuum pump, and then by means of steam coils. The sulphur distils from the precipitate at 450° C. and the distillate is practically pure. The reduction of the barium sulphite or sulphate is effected by heating the residue with carbon, coke, or coal at 750° to 1200° C., preferably with carbon of high purity, at a high temperature in an externally heated furnace so as to avoid the introduction of inert substances, such as ash, etc. Any oxide or carbonate formed is converted into sulphate by treatment with sulphuric acid or into sulphite by agitation with sulphur dioxide solution. When coal is used for the reduction it may be necessary to extract the barium sulphide with water, and reject the insoluble matter. It is estimated that in certain localities the cost of producing sulphur by this method would be about \$12 per ton.—C. A. M.

Mineral and metal output of Japan in 1916.

THE Japanese Bureau of Mines reports that the quantity and value of minerals and metals produced in Japan in 1915 and 1916 were as follows:—

		1914.		1915.		1916.	
		Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
			Yen.		Yen.		Yen.

is reduced to sulphide and used for a fresh operation. In experiments on a large scale it was found that with the mother liquor as absorbent it was possible to obtain solutions containing 30% more sulphur dioxide than is theoretically possible with water, and which also retained the bulk of the sulphur dioxide. For a commercial operation the cases should contain at least 5% of sulphur dioxide, and the temperature of the absorbing liquid should be less than 25° C. The principal barium product is the thiosulphate rather than the sulphite. If sufficient barium sulphide is added to combine with most of the sulphur dioxide, but little barium salt remains in solution, and the sp. gr. of the liquid does not exceed 1.03. In presence of a large excess of sulphur dioxide after the reaction, part of the barium is dissolved as thiosulphate. The best method of incorporating the barium sulphide is to emulsify it with a portion of the sulphur dioxide solution, and to mix this emulsion with the bulk of the solution in a tank containing an agitator. The precipitate settles readily and does not contain more than 50% of water, and it can be dried by draining

A deposit of molybdenite was recently discovered at Iwanezawa Kamitsuga-gori, Tochigi Prefecture, and a company with headquarters at Tokio has been formed to carry on mining operations and the refining of the ore. The capital of the company is 1,000,000 yen.

Mineral exports from New Zealand. Board of Trade J., Oct. 11, 1917.

THE Mines Statement for the year 1916 by the Dominion Minister of Mines, shows that the total value of minerals exported, together with the coal consumed in New Zealand, in 1916 amounted to £2,978,436, as compared with £3,374,523 in 1915, a decrease of £396,087. The decrease is confined almost entirely to gold, the export in 1915 having been larger than usual owing to shipments of much of the output of 1914, when the export of gold was prohibited during the later months. The following table shows the quantity and value of the various minerals exported from the Dominion in 1915 and 1916, and the quantity and value of the coal consumed in the country:—

	1915.		1916	
	Quantity.	Value.	Quantity.	Value.
Gold	oz. 122,825	£ 1,691,583	oz. 292,620	£ 1,199,212*
Silver	597,511	75,583	587,053	75,111
	tons.		tons.	
Tungsten ore	194	27,784	266	49,070
Coal Exported	323,992	329,731	328,187	326,553
Coal Consumed	1,881,632	942,316	1,928,652	964,476
Kauri gum	775	279,133	3,448	339,343
Other minerals	3,473	5,423	7,368	11,671

* The value of bullion produced, as stated in the official returns from the mines, was £1,192,107.

In the gold-mining industry there was a revival of interest during 1916 in West Coast alluvial mining, as the result of payable prospects being obtained at Rima Falls by an Australian company, and a number of claims were taken up by strong proprietaries. Gold dredging continues to decline. The quantity and value of the exports of tungsten ore during 1916 constituted a record for the Dominion.

By-products from the manufacture of tin plate [as feeding stuffs]. See XIXA.

PATENTS.

Iron; Refining of — A. Rollason, Nottingham. Eng. Pat. 109,178, Dec. 12, 1916. (Appl. No. 17,825 of 1916.)

SILICON and carbon are first removed from the pig-iron by running the molten metal from a blast or cupola furnace into an ordinary acid-lined converter, where it is blown by a blast delivered through side tuyères and also subjected to surface oxidation. The metal is then run into a basic-lined converter fitted with an extra set of tuyères and, after adding lime, the metal is blown to remove phosphorus and sulphur. Deoxidation and the final refining of the metal are effected by transferring to an electric furnace together with the silicious slag from the acid-lined converter and any other material necessary for the refining. A low-voltage alternating current is employed for the heating and to cause circulation and intimate contact of the metal with the slag. The refined metal is run into ladles and cast into ingots.—J. N. P.

Iron and steel; Process for manufacturing from oxygen-containing baths. A. Klinkenberg, Dortmund, Germany. U.S. Pat. 1,238,409, Aug. 28, 1917. Date of appl., Apr. 6, 1917.

PACKAGES of cellulose or other carbohydrate material in a finely divided condition are introduced into the ingot mould, so that the oxides are reduced when the molten metal is poured into the mould.—J. N. P.

Titaniferous-iron ores; Process of reducing — W. A. Loke, The Hague, Holland. Eng. Pat. 109,328, Oct. 1, 1916. (Appl. No. 14,116 of 1916.)

TITANIFEROUS iron ore and pyrites are finely ground and well mixed in such proportions that the oxygen of the former is slightly in excess of the quantity required to combine with the sulphur of the pyrites, and the mixture is heated in an electric furnace to a temperature sufficiently high to effect a slight reduction of the titanium oxide, so that the liberated titanium may purify the iron. The sulphur dioxide which is evolved may be used for the manufacture of sulphuric acid, and the slag, consisting of titanous acid and other titaniferous compounds, is used for further desulphurising the iron. If after the reduction

the iron still contains sulphur, fluorspar and ferrosilicon are added to free the slag from iron, and the desulphurisation continued.—J. N. P.

Hardening or tempering and brazing steel; Compound for use in — C. Buckler, Leeds. Eng. Pat. 109,566, Jan. 22, 1917. (Appl. No. 1049 of 1917.)

A COMPOSITION for use in hardening, tempering, or brazing steel, to prevent surface oxidation, consists of boric acid 186 parts, flour 2 parts, salt 2 parts, sal ammoniac 3 parts, sugar of lead 3 parts, blue stone 1 part, and rouge 3 parts. The composition may be used as a powder, or, mixed with soft soap, as a paste.—W. F. F.

Ferro-uranium alloy. Nickel-uranium alloy. Process of manufacturing ferro-uranium. R. M. Keeney and L. F. Vogt, Washington, Pa. Assignors to Standard Chemical Co., Pittsburgh, Pa. U.S. Pats. (A) 1,210,054, (B) 1,240,055, and (C) 1,210,056, Sept. 11, 1917. Dates of appl., (A) and (B) Dec. 21, and (C) Dec. 28, 1915.

(A) A FERRO-URANIUM alloy contains 25–30 % uranium and more than 60 % iron. (B). The iron in (A) is replaced by nickel. (C) The alloy described in (A) is made by mixing subdivided iron with uranium oxide, a carbonaceous reducing agent, and a neutral slag-forming material such as fluorspar, and heating the mixture to a temperature above the melting point of iron.—W. F. F.

[Palladium-gold] alloy. Electro Metals Products Co., Assignees of H. S. Cooper, Cleveland, Ohio, U.S.A. Eng. Pat. 109,176, Dec. 8, 1916. (Appl. No. 17,669 of 1916.) Under Int. Conv., Sept. 29, 1916.

AN alloy composed of 60 % palladium and 40 % gold has a melting point approximating to that of pure palladium and higher than that of the alloy containing equal weights of the metals. It resists the action of acids and gases and high temperatures, thus forming a useful substitute for platinum in the preparation of laboratory ware and for dental purposes.—J. N. P.

Metallic bodies; Improvements in — [Modification of crystal structure.] J. Pintsch Akt.-Ges., Berlin. Eng. Pat. 109,298, Sept. 5, 1916. (Appl. No. 12,583 of 1916.) Addition to Eng. Pat. 16,620 of 1914 (see Fr. Pat. 469,212 of 1914; this J., 1915, 36).

THE crystal structure of metal rods, wires, filaments, or ribbons, is modified so that a single crystal extends throughout the whole length and cross section of the metal, by passing the body through a source of heat either *in vacuo* or in an enclosed space filled with a reducing or inert gas, at a speed which is not greater than the rate of growth of the crystal formation. The apparatus is arranged to give a gradual preheating of the metal, followed by a rapid rise to the maximum temperature, a sudden fall, and then gradual cooling. The wires or rods are passed down a thin-walled tube at the lower end of which is a spherical or rectangular chamber, and through the centre of a loop of wire which is arranged in the interior of the chamber in a plane at right angles to the axis of the travelling metal, and can be raised to a high temperature by the passage of an electric current. In alignment with the top tube, and passing through the lower part of the chamber, is the second tube, the upper part of which extends into the chamber to a distance which can be adjusted. The tubes and chamber are insulated in such a manner that the heat radiated from the spiral of wire in the centre produces the necessary gradient of temperature throughout the apparatus. Auxiliary heating of the metal can also be arranged by passing a current through the

rod or wire under treatment. For this purpose the ends of the tubes are closed by plates provided at their centres with fine borings at the upper ends of which mercury wells form air-tight seals between the plates and the travelling metal. The mercury seals serve as contacts for introducing a heating current through the wires, etc., and are cooled and the formation of arcs checked by causing a current of gas to impinge on the surface. Intermediate contacts of this nature may be arranged at intervals in the tube so as to limit or vary this auxiliary heating to a certain section of the metal. Several wires may be passed parallel to each other and thus treated simultaneously in this apparatus, without extra consumption of current. Wires and filaments prepared by this method may be worked or even drawn cold through dies without breaking down the crystal structure. —J. N. P.

Depositing metal by an electric arc: Method of and means for —, E. H. Jones, London. Eng. Pat. 109,321. (Appl. Nos. 13,342, Sep. 20, 1916, and 3864, Mar. 16, 1917.)

In the production of metal deposits by sustained deposition by means of an electric arc, heat is applied to the deposited metal to render it homogeneous and free from blow-holes and similar defects. In order to confine the fused metal during deposition, the part of the article to be treated is surrounded by a refractory mould, which is conveniently prepared from a mixture of slaked lime or the residue from the manufacture of acetylene from calcium carbide with 5–10% sodium silicate. The process may be applied to the production of a cutting edge of high-speed steel on a base of mild steel by local deposition of metal, or to the deposition of hardened metal on bearing surfaces. —J. N. P.

Metal electrodes used in electric arc soldering and deposition of metals: Method of forming —, E. H. Jones, London. Eng. Pat. 109,652, Sept. 20, 1916. (Appl. No. 13,343 of 1916.)

A METAL electrode for electric arc soldering or deposition of metals, e.g., high-speed steel, comprises one or more mild steel or cast iron cases of channel section, in one of which a rod containing carbon, e.g., of cast iron, carbon, or ferro-chrome, is placed. The remainder of the case is filled with the material to form the high-speed alloy, such as vanadium, cobalt, tungsten, molybdenum, chromium, with or without aluminium, mixed with a suitable binding agent such as sodium silicate. These materials may be previously moulded in the desired shape by extrusion and allowed to set. The electrode is enclosed in a suitable covering such as asbestos yarn soaked in sodium silicate solution, and powdered aluminium. —W. F. F.

Nickel-copper matte; Process for refining —, C. Langer, Clydach, Glamorgan. Eng. Pats. (A) 109,401 and (B) 109,402, Mar. 17, 1917. (Appl. Nos. 3904 and 3905 of 1917.)

(A) BESSEMERISED nickel-copper matte is reduced to a fine powder, and calcined so as to convert the nickel and copper into oxides, which are then leached with a solution of about 10% sulphuric acid at about 80° C., when 60–80% of the copper oxide is dissolved as sulphate. The solution is filtered off, the residue is dried, reduced to a powder containing about 60–65% of nickel, and used to displace copper from the copper sulphate solution. The nickel can be recovered from the solution by electrolysis with insoluble anodes, or the sulphate can be recovered as such by crystallisation, while the precipitated copper can be cast into anodes and refined by electrolysis, or converted into oxide by calcination and dissolved in

dilute sulphuric acid to form copper sulphate. (B) After treatment of the finely ground calcined nickel-copper matte with dilute sulphuric acid so as to dissolve the bulk of the copper, the residue is treated with strong sulphuric acid at about 150° C. and the sulphates produced are separated by dissolving in water, precipitating the copper from the solution by finely divided metallic nickel, and finally recovering the nickel from its solution by electrolysis. —J. N. P.

Copper-nickel pyrrhotite; Treatment of —, W. McA. Johnson, Assignor to Continuous Zinc Furnace Co., Hartford, Conn. U.S. Pat. 1,238,298, Aug. 28, 1917. Date of appl. Oct. 22, 1913.

THE material is crushed to a fine powder and subjected to the action of chlorine in closed chambers, whereby sulphur is displaced and volatilised. The resulting chlorides are dissolved in water, and after removal of copper and precious metals by adding scrap iron, iron and cobalt are precipitated as hydroxides, the hydroxides are dissolved, and the iron and cobalt precipitated separately. Nickel is separated as chloride from the remaining solution by evaporation and crystallisation, and the chloride is reduced to the metal by heating with hydrogen in a closed retort. —J. N. P.

Metallic debris; Preventing corrosion or waste in —, F. E. Whitham, Sowerby Bridge, Yorks. Eng. Pat. 109,749, Apr. 17, 1917. (Appl. No. 5375 of 1917.)

METAL turnings, especially aluminium, which have been subjected to the action of an alkaline liquid used as a lubricant for the cutting tool, are treated with an acid bath to neutralise the alkali and prevent corrosion. If the metallic debris has been subjected to the action of acid, an alkaline bath is used. —W. F. F.

Hardening metal articles; Apparatus for —, L. Renault, Billancourt, France. Eng. Pat. 109,596, June 20, 1917. (Appl. No. 8866 of 1917.) Under Int. Conv., Sept. 13, 1916.

APPARATUS for hardening a succession of similar articles comprises a vertical cylinder in the bottom of which the article is supported on a rotating stand provided with helical grooves. For each hardening operation, liquid from a measuring tank is poured through a funnel into the cylinder, and falling on the grooved stand, causes it to rotate. If the article is hollow an additional funnel and pipe are provided leading into its interior, the funnel receiving a proportion of the liquid from the tank. The main cylinder is raised and lowered as each article is replaced, and the tank is automatically refilled to a predetermined level at the same time by a float actuating an electrical device which controls the liquid supply. —W. F. F.

Annealing and like furnaces; Doors of gas-heated —, Dowson and Mason Gas Plant Co., Ltd., T. Wright, and E. W. Mawby, Manchester. Eng. Pat. 109,755, May 1, 1917. (Appl. No. 6353 of 1917.)

IN a gas-heated annealing or like furnace, the inlet door is hinged horizontally on a part of the door frame which projects forward. When closed the door is slightly inclined, with its lower edge resting on the lower part of the frame, and it can only open inwards. Cold air is prevented from entering and hot air from leaving the annealing chamber at the sides of the door when opened by the projecting part of the door frame. In a modification having three adjacent doors which open outwards, side plates are provided projecting

outwards from the door frames at the two outer ends, and similar plates are attached to the inner edges of the two side doors. These two doors or all three doors may thus be opened without allowing air to enter or leave at the sides.

W. F. F.

Furnaces of the crucible or like type. Richmond Gas Stove and Meter Co., Ltd., and H. Hartley, Warrington, Eng. Pat. 109,586, Apr. 16, 1917. (Appl. No. 5536 of 1917.)

A GAS-HEATED crucible furnace is divided by a vertical wall into two parts, one of which constitutes the crucible chamber, whilst the other part is divided into two compartments, the upper of which is used for preheating the metal or other substance. The lower compartment is fitted with two sets of U-pipes, through which passes the air required by the gas-burner. These pipes are heated by the products of combustion of the furnace and thus heat the incoming air recuperatively.

A. B. S.

Magnetic separator. The Hardy Patent Pick Co., Ltd., and G. J. McD. Smith, Sheffield, Eng. Pat. 109,766, June 4, 1917. (Appl. No. 7473 of 1917.)

A MAGNETIC separator comprises a horizontal brass cylinder containing the material to be separated, surrounded by radial electromagnets, the whole being rotatable. Each magnet as it reaches its highest point is demagnetised and the magnetic particles on the wall of the cylinder fall into a discharge shoot. To prevent the magnet at this point from being influenced by adjacent energised magnets, and the retention of the magnetic particles in consequence, intermediate radial iron arms are provided which are magnetised by induction with an opposite polarity. The radial arms also increase the intensity of the magnetic fields of the electro-magnets. W. F. F.

Ores; Process of extracting metals from — E. T. Stannard, Kennecott, Alaska, Assignor to Kennecott Copper Corporation, New York. U.S. Pat. 1,238,951, Sept. 4, 1917. Date of appl., Aug. 7, 1916.

THE ore is leached with a volatile solvent, the solution withdrawn, and the metal and volatile reagent recovered; steam is then passed through the charge; the condensed water removes any remaining metal-bearing solution, and the volatile reagent is recovered from the liquid. The treatment with steam may be continued until the charge is hot and condensation no longer takes place; the escaping steam is condensed and treated separately for recovery of volatile reagent. By washing the ore partly with the condensed liquid and partly with live steam, smaller volumes of stronger leaching solutions may be obtained.

W. R. S.

Electrolytic cell [for deposition of copper]. N. V. Hybinette, Christiania, Norway. U.S. Pat. 1,239,612, Sept. 4, 1917. Date of appl., May 22, 1913.

AN electrolytic cell for use in the deposition of copper from copper sulphate solutions containing iron sulphate, is composed of a tank in which anodes are suspended. A number of vessels are also suspended in the tank in such a manner that they can be removed, each vessel having a lower porous portion below the top of the tank separating the anodes from the cathodes, and an upper non-porous portion extending above the tank. A cathode is suspended in each vessel, with means for supplying the electrolyte directly to the

vessels; the non-porous portion co-operates with the supply means to maintain the solution in each cathode chamber under atmospheric pressure, but above the level of the solution in the anode chamber. Means are provided for regulating the difference between the levels, so as to control the amount of solution passing through the porous portions of the vessels. The solution is withdrawn from the anode chamber by suitable means, and overflow channels, passing over the edge of the tank, are arranged for withdrawing solution from the cathode chamber.—B. N.

Electrolytic deposition; Apparatus for — P. L. Antisell, Perth Amboy, N.J. U.S. Pat. 1,239,443, Sept. 11, 1917. Date of appl., Oct. 31, 1913.

THE cathode sheets are suspended from conducting members connected to the electrolytic tank, and a receptacle is arranged between the cathode sheets to act as anode, with an open top for the passage of particles of conducting material and solution. The receptacle is provided with a bottom for supporting the particles of conducting material, but permitting the passage of liquid, and conducting members, extending into the receptacle, are arranged to form a wet contact with the material. The anode receptacle has closed ends and open sides, the latter being covered with "rotary cut veneer" porous diaphragms, supported by the sides and by rods attached to the receptacle. Electrolyte is supplied to the tank and receptacle, and means are provided for circulating the solution through the anode and removing it from the tank.—B. N.

Ores; Process for treating — N. C. Christensen, jun., Assignor to Holt-Christensen Process Co., Salt Lake City, Utah. U.S. Pat. 1,239,167, Sep. 4, 1917. Date of appl., Mar. 10, 1915.

IN roasting ores, the coarser particles are screened out and a portion spread uniformly over the roaster grate; a moistened mixture of ore, salt, and sulphides is spread uniformly upon the coarse material, and the upper layer is loosened by disturbing the lower one. The upper portion of the top layer is heated to ignite the sulphides, the roasting being accomplished by a downward current of air. The coarse particles are again screened out of the roasted mixture and used over again. The whole process is carried out continuously.—W. R. S.

Alkali-earth metals [magnesium]; Process for obtaining — W. M. Grosvenor, Ridgewood, N.J. U.S. Pat. 1,239,178, Sep. 4, 1917. Date of appl., Feb. 3, 1916.

MATERIAL containing magnesium oxide is heated for a long time in a current of inert gas, e.g., hydrogen, nearly to the temperature at which magnesium vapour would be liberated, so as to remove volatile impurities, then heated with a suitable reducing agent to a point not far above the temperature at which metallic magnesium is formed, to avoid volatilisation of more refractory impurities; the magnesium vapour is condensed. The material must be sufficiently basic to have a melting point above the volatilising point of magnesium.—W. R. S.

Agglomerating ore; Machinery for — P. O. Harding, Rancagua, Chile. U.S. Pat. 1,239,179, Sep. 4, 1917. Date of appl., Jan. 15, 1917.

A SINTERING machine comprises a vertical tubular sintering-chamber, and above it a stationary conveyor with a tapered, radial delivery orifice and a spreader beneath the conveyor. A rotary shoot is provided between the delivery orifice and the top of the sintering-chamber.—W. R. S.

Ores and substances; Process for the treatment of — F. L. McGrahan, Los Angeles, Cal. U.S. Pat. 1,239,282, Sep. 4, 1917. Date of appl. Feb. 26, 1914.

THE process consists in smelting the ore, drawing off the liberated gases and partly condensing them, superheating the remainder, and returning it to the furnace. The condensed portion is separated into its constituent products.—W. R. S.

[*Solder.*] *Composition of matter.* W. A. Day, Bellingham, Wash. U.S. Pat. 1,239,465, Sept. 11, 1917. Date of appl. Mar. 12, 1917.

A SOLDER for cast iron, mild steel, pot-metal, aluminium, lead, and the like is composed of lead, 5 parts, tin, 5 parts, and zinc, 1 part.—W. F. F.

Soldering compound. G. Gardiner, East Cleveland, Ohio. U.S. Pat. 1,239,785, Sept. 11, 1917. Date of appl. May 1, 1916.

A SOLDERING compound consists of tin, 35 parts, zinc, 17.5 parts, copper 1 part, and antimony, 0.02 part.—W. F. F.

Welding and soldering of articles constructed of aluminium; Composition of matter for the — O. C. Wells, Fort Worth, Tex. U.S. Pat. 1,239,854, Sep. 11, 1917. Date of appl. June 23, 1917.

A COMPOSITION for welding and soldering aluminium consists of aluminium, 1 part, lead, 3 parts, block tin, 7 parts, and zinc, 2 parts.—W. F. F.

[*Iron tungstate*] *ores; Process for treating* — H. E. Cleaves, Washington, D.C. U.S. Pat. 1,239,885, Sep. 11, 1917. Date of appl. Mar. 9, 1917.

ORES or compounds containing one or more of the metals of the fifth and sixth groups, e.g., an ore containing an iron tungstate mixed with undesirable metals or metalloids, are treated at a temperature above red heat with non-oxidising gas containing hydrogen chloride and a reducing agent. Iron and tungsten chlorides are formed and volatilised, and the stream of gas containing them is passed into water where tungsten oxide is precipitated. The hydrogen liberated combines with part of the metalloids, and the reducing agent is present only in such quantity as is necessary to prevent the formation of free chlorine by reacting with the excess of metalloids not combined with hydrogen.—W. F. F.

Minerals; Flotation of — C. L. Perkins, Pittsburgh, Pa., Assignor to Metals Recovery Co., New York. U.S. Pats. (A) 1,240,597, (B) 1,240,598, and (C) 1,240,599, Sept. 18, 1917. Date of appl. Aug. 2, 1917.

A SMALL amount of (A) β -naphthylamine or (B) xylydine and other agents, with sufficient alkali to give a distinct alkaline reaction, is added to the mineral pulp, and the resulting mixture subjected to flotation. (C) A mixture of α - and β -naphthols and other agents is added to the mineral pulp, and the whole subjected to flotation.—T. H. B.

Carnotite ores; Concentrating — H. Schlundt, Columbia, Mo. U.S. Pat. 1,240,607, Sept. 18, 1917. Date of appl. June 16, 1916.

CARNOTITE ores and other materials containing radium are heated with nitre cake at a temperature sufficient to dissolve the radium together with barium as sulphates. The resulting solution is poured into water while still liquid; the radium barium sulphate is thus precipitated in a finely divided condition, and is afterwards separated from the undissolved material.—T. H. B.

Magnetic material (iron); Process for making — British Thomson-Houston Co., Ltd., London. From General Electric Co., Ltd., Schenectady, N.Y., U.S.A. Eng. Pat. 109,528, Nov. 8, 1916. (Appl. No. 16,008 of 1916.)

SEE U.S. Pat. 1,291,623 of 1916; this J., 1916, 1222.

Aluminium shavings, screenings, dross, slags, or analogous materials; Process for treating — H. A. Gill, London. From W. F. Jobbins, Inc., Aurora, Ill., U.S.A. Eng. Pat. 109,716, Mar. 23, 1917. (Appl. No. 1295 of 1917.)

SEE U.S. Pat. 1,228,119 of 1917; this J., 1917, 888.

Crucible furnace. G. and J. Keith, London. U.S. Pat. 1,241,597, Sept. 25, 1917. Date of appl. Oct. 23, 1916.

Method of agglomerating finely-divided material — U.S. Pat. 1,239,221. See 1.

Manufacture of crystalline fused alumina (and ferrosilicon and alkali compounds). U.S. Pat. 1,239,984. See VII.

XI.—ELECTRO-CHEMISTRY.

Electrical fume precipitation; Some theoretical aspects of — W. W. Strong. Joint meeting of Amer. Electrochem. Soc. and Amer. Inst. Min. Eng., Jan. and May, 1917. [Advance copy.] 16 pages.

THE rapid progress which has been made in the past few years in the application of electrical fume precipitation is due largely to the technical advances in the construction of apparatus for the production of high-voltage electric currents, the theoretical side of the process having received comparatively little attention. In the simplest form of electrical precipitation apparatus, namely a wire (charged negatively) arranged axially within a cylinder, with a high difference of electrical potential between the two, three different regions may be distinguished: the inner zone is the region of active electrode rays or positive ion rays and positive space charges, whilst the outer zone is the region of passive electrode rays and negative space charges; intermediate is the zone where the gas molecules become charged by collision with ions. In electrical precipitation it is important to keep the fumes as far as possible within the region of passive electrode rays and negative space charges. The space charge effects of the small ions of the corona discharge do not interfere with electrical precipitation, any choking of corona currents by space charges being due to the large ions. If the effect of space charges be neglected, the formation of ions in a gas is probably not greatly affected by fumes and smoke, but the nature of the fume particles probably greatly affects the ease with which they hold ions. Some substances, such as zinc oxide, may reflect ions that collide with them, but in such cases formation of a thin layer of some conducting substance over the surface of the particles may make it possible to charge them. The greater the space charge in a treater the less is the voltage that can be applied. In practice a pipe having a diameter about 30 times the diameter of the corona is used. It is suggested that in the future development of the process, in addition to advances in regard to the more efficient charging of the suspended particles and the maintenance of the corona at its maximum value more continuously and uniformly, the practicability of utilising the chemical power of the corona discharge as well as its precipitating power will have to be considered.

PATENTS.

Electric discharge apparatus. C. Field-Frank, New York. Assignor to General Electric Co. U.S. Pat. 1,238,660, Aug. 28, 1917. Date of appl., Jan. 27, 1916.

ELECTRODES consisting of two metallic plates are arranged parallel to one another in a case of insulating material which is filled with a dry flocculent oxide of lead prepared by heating the precipitated peroxide. A conducting path of high resistance is thus formed between the electrodes, the passage of a large current being checked by an increase in resistance of the material in the path between the electrodes, due to the change produced in the oxide on elevation of temperature.—J. N. P.

Furnace; Electric——. E. F. Price, Port Chester, N.Y.. Assignor to Electro-Metallurgical Co., New York. U.S. Pats. (A) 1,239,211 and (B) 1,239,215, Sep. 4, 1917. Date of appl., Feb. 1, 1917.

(A) A CAST-METAL base, made in segments, is provided with a cooling arrangement, and with a hearth or bed of carbonaceous material, the hearth and the base being separated by a series of overlapping metal sheets. (B) The furnace has a movable electrode, with a flexible conductor in the circuit leading to it, and a flexible shield is disposed between the flexible conductor and the furnace, the shield being movable with the conductor but insulated from it.—B. N.

Electrolytic apparatus. H. T. Shriver, West Orange, N.J. U.S. Pat. 1,239,530, Sept. 11, 1917. Date of appl., May 25, 1915. Renewed Apr. 17, 1916.

AN electrolytic apparatus of the filter-press type is composed of a number of cells in series, formed from vertical parallel recessed plates, held face to face. A diaphragm is arranged between each pair of recessed plates, and means are provided for maintaining the electrolyte, which is heavier than water, at approximately a predetermined level, the diaphragm being porous below and non-porous above the normal level of the liquid. A horizontal diluent supply duct is connected by means of auxiliary ducts with the lower parts of the cells, and means are provided for placing the diluent in the various ducts under pressure, the pressure means and the auxiliary ducts being constructed and arranged so that the diluent flows from the supply duct to the cells and not in the reverse direction. Main gas ducts, extending through the plates, are connected to each of the cells to carry away the gas formed at the anodes and cathodes respectively. The pressure is sufficient to cause water, as a diluent, to flow into the cells when the level of the electrolyte falls below the normal, but is insufficient to cause the electrolyte to flow into the main gas ducts.—B. N.

Insulating compound and method of producing the same. J. W. Harris, Montclair, N.J.. Assignor to Western Electric Co. U.S. Pats. (A) 1,240,565, (B) 1,240,566, and (C) 1,240,567, Sept. 18, 1917. Date of appl., Mar. 5, 1915.

(A) A MIXTURE of resin and castor oil is heated at 250° to 310° C. until from 5 % to 15 % of the decomposition products of the castor oil has been distilled off. The article to be protected is coated with the residue and heated to 300° C. (B) A mixture of castor oil and a metallic soap of castor oil or (C) a mixture of a metallic resinate and castor oil, is subjected to destructive distillation at a temperature, about 300° C., sufficiently high to produce a solid, insoluble substance. The mixture is heated either on the article to be protected or in the desired shape of the insulating material.—B. V. S.

XII.—FATS; OILS; WAXES.

Fats and oils; Method for fractionating——. A. Seidenberg. J. Ind. Eng. Chem., 1917, 9, 855—858.

THE fat is dissolved in two or more solvents (e.g. alcohol and ether), one of which is more volatile than the other and has a greater solvent action upon the glycerides. Air is aspirated through the solution, causing a gradual evaporation and considerable decrease in the temperature, and the glycerides which successively separate are removed. In this way a fractionation of the glycerides in the order of their insolubility is effected, and pure products may be obtained by combining similar fractions and repeating the fractionation as many times as is necessary. By thus fractionating 100 grms. of tallow dissolved in 1000 c.c. of a mixture of ether and absolute alcohol (1:1), and re-fractionating the deposits from mixtures of alcohol and ether, about 0.98 grm. of a mixed glyceride (oleodistearin), and about 20.6 grms. of a more soluble glyceride, dioleopalmitin were isolated. No evidence of the presence of triolein was obtained. The method may be adapted to the detection of beef or mutton fat in butter fat. Thus a sample of pure butter fat when fractionated from mixtures of ether and 95 % alcohol yielded 3.8 % of insoluble glycerides, whilst the same fat to which 20 % of tallow had been added, yielded under the same conditions, 0.9 % of insoluble glycerides.—C. A. M.

Fats and oils; Thermal values of——. II. The sulphuric acid or Maumené value. J. W. Marden and M. V. Dover. J. Ind. Eng. Chem., 1917, 9, 858—860. (See also this J., 1916, 477.)

THE apparatus consists of a Dewar vacuum tube, through the cork of which is passed a large test-tube, in which the oil and acid are stirred by means of an agitator. The calorimeter is standardised by mixing therein a weighed quantity of sulphuric acid of known strength with a weighed quantity of water, and calculating the heat liberated after the temperature has become constant. If the same weights of acid, oil, and water are always used, the heat capacity of the system may be considered constant. The rise in temperature, multiplied by the heat capacity of the system divided by the weight of oil, gives the Maumené value in cal. per grm. of oil. Variations in concentration of the acid have a considerable effect upon the results, but the amount of acid may be varied without greatly affecting the thermal value. The specific heats of a number of fats and oils were determined by a method similar to that used for determining the heat capacity of the apparatus. They showed only slight variations (0.438 to 0.551). Duplicate determinations of the Maumené value agreed within 0.5 %. The values obtained by treating

typical oils with an excess of 95.1 % sulphuric acid were of the same order of magnitude as the corresponding iodine values.—C. A. M.

Sulphonated oils: Analysis of — R. Hart.
J. Ind. Eng. Chem., 1917, 9, 850—852.

THE fat is determined by titrating a solution of the oil with N/2 sulphuric acid, using methyl orange as indicator, and the alkalinity (from the soap) is expressed in mgrms. of KOH per gram. Another portion of the sample is used for the determination of the saponification value in the usual way, and the sum of the two results divided by the neutralisation value of the fatty acids of the original castor oil gives the percentage of fat. In cases where the neutralisation values of the fatty acids are not known, the average value of 190 may be taken. Ammonia is determined by boiling a portion of the solution with a measured excess of N/2 alcoholic sodium hydroxide to expel ammonia and titrating the liquid with N/2 sulphuric acid. The alkalinity of a second portion is then determined, omitting the boiling with caustic soda, and the difference between the two results corresponds to the ammonia. In calculating the saponification value allowance must be made for the fat corresponding to the ammonium soap, which acts like fatty acids during the saponification. *Combined sulphuric anhydride*:—The oil is boiled with a measured quantity of standard sulphuric acid until completely decomposed:

It is then titrated with standard alkali solution, using methyl orange as indicator, and the net change in the acidity is equal to the difference between the total alkalinity due to the soap, and the acidity due to the sodium bisulphate. The total alkalinity of the original sample is determined as described, and from these data the acidity corresponding to the sodium bisulphate, or combined sulphuric anhydride, may be calculated. The results agree closely with those obtained by the usual gravimetric method.—C.A.M.

Method of testing [viscosity of] lubricating oils.
Dubrisay. See IIA.

PATENT.

Catalyser for hydrogenating oils and the like. M. H. Ittner, Jersey City, N.J. U.S. Pat. 1,238,774, Sept. 4, 1917. Date of appl., May 14, 1914.

A CATALYST comprises a catalytic material, viz., a metal (nickel) coated with catalytic oxide (a low oxide of nickel), associated with charcoal impregnated with a catalytically activating inorganic compound, e.g., a silicate, or oxygen compound of aluminium.—E. W. L.

Process for cleaning filters in connection with the purification of sugar, oils, and chemicals. U.S. Pat. 1,240,290. See I.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

PATENTS.

Titanic acid pigment products; Manufacture of — H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pat. 108,875, June 15, 1916. (Appl. No. 8464 of 1916.)

A COMPOSITE pigment is obtained by adding a

solution or suspension of an alkaline-earth base or sulphide to a titanic sulphate solution, whereby orthotitanic acid is precipitated coalesced with insoluble alkaline-earth sulphate. The alkaline-earth sulphate may be replaced by a so-called "extender pigment" (barites, silica, china clay, etc.) by adding a solution of alkali hydroxide, carbonate, or sulphide to a suspension of such "extender pigment" in a titanic solution. The composite precipitate is subsequently calcined. The titanic solution is previously freed from metallic compounds of the copper group by treatment with hydrogen sulphide and filtering off the precipitated sulphides. Iron as an impurity is removed by employing a soluble sulphide for precipitation of the pigment: the iron sulphide formed is dissolved by passing sulphur dioxide into the solution.—A. DE W.

Decorative surfaces; Treatment of — G. H. Hadfield, Merton, and A. E. Baytree, Sutton, Surrey. Eng. Pat. 109,857, Sept. 21, 1916. (Appl. No. 13,437 of 1916.)

SURFACES coated with varnishes containing Chinese wood oil, linseed oil, or other drying oil, are subjected to the action of vapours of nitric acid "or its equivalent" whereby a crystalline, matt, or honeycombed structure in the surface is formed, or the film hardened or coloured according to the conditions of temperature, etc., and the particular gases or vapours employed. A "nitric acid equivalent" is defined as any gas or vapour capable of modifying the colour, hardness, or structure of the uniform glossy film obtained under the ordinary conditions of drying in pure air at ordinary or elevated temperatures. The vapour in an internally heated gas oven which causes certain wood oil varnish films to assume crystalline structure is not claimed as a "nitric acid equivalent." Several methods of producing variations of surface are quoted, e.g., the presence of sulphur dioxide in the gas is claimed as being responsible for deepening of colour at ordinary temperatures: local effects are obtained by superimposing layers of varnishes with no tendency to crystallise, etc., under any conditions; the flash point of the thinner employed governs the size of the mesh or crystal obtained.—A. DE W.

Paint; Luminous — G. A. H. Muller, Montreal, Canada. U.S. Pat. 1,237,368, Aug. 21, 1917. Date of appl., June 8, 1916.

A BASE of luminous calcium sulphide is prepared by heating caustic lime with sulphur, and is purified by heating it with calcium fluoride, which forms volatile compounds with the impurities. Other substances may be added for colouring purposes.—E. W. L.

Lampblack and hydrochloric acid; Process of making — C. C. Averill, Trees, La. U.S. Pat. 1,238,734, Sept. 4, 1917. Date of appl., Apr. 6, 1917.

A HYDROCARBON, e.g., natural gas, is burned in an atmosphere of chlorine in a closed chamber from which air is excluded; the carbon is allowed to settle and the hydrochloric acid is drawn off.

—E. W. L.

Sealing wax. W. O. Snelling, Pittsburgh, Pa. U.S. Pat. 1,239,629, Sept. 11, 1917. Date of appl., Oct. 14, 1915.

THE sealing wax is composed of resin, a filling material, a colouring material, and a vaporisable, solid or semi-solid, fire-extinguishing, halogenated carbon compound, such as hexachloroethane.

—B. N.

Titanic oxide products (pigments); Method for producing composite—L. E. Barton, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York, U.S. Pat. 1,240,405, Sept. 18, 1917. Date of appl. June 8, 1916.

See Eng. Pat. 108,875: preceding.

Process for making a filler for rubber or paint.—U.S. Pat. 1,237,701. See XIV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber: Influence of the amount of acetic acid [used for coagulation] on the qualities of—O. de Vries, P. Arens, and N. L. Swart. Communication from the Central Rubber Station at Buitenzorg, No. 2. *Archief voor de Rubbercultuur in Ned. Indie*, 1917, 1, No. 1.

THE slight variation in the proportion of acetic acid used in estate practice is not likely to be a factor affecting the inner qualities of the rubber; with varying quantities of acetic acid ranging from the minimum to four times as much, the tensile strength and "type" were found to be unaffected, whilst the rate of vulcanisation was reduced, e.g., by 10 minutes on 135 with the quadruple amount of acid, and the viscosity was also decreased somewhat.—D. F. T.

Cripe rubber; Influence of rolling on—O. de Vries and N. L. Swart. Communication from the Central Rubber Station at Buitenzorg, No. 2. *Archief voor de Rubbercultuur in Ned. Indie*, 1917, 1, No. 1.

A CONFIRMATION of the results of Eaton and Grantham (this J., 1910, 263), and Campbell (Bull. Depart. Agric. Ceylon, 24,) that creping of much longer duration than that practised on rubber estates, either with smooth or grooved rolls, causes no appreciable diminution in tensile strength, viscosity, or rate of vulcanisation. As long as the rolls are kept cool, a reasonable variation in the number of times for which the rubber is passed through the rolls is without influence on the internal qualities of the rubber, although, for the sake of cheapness in production, it is desirable to roll as little as is consistent with a good external appearance.—D. F. T.

Vulcanisation; The most practical accelerator of—A. Hutin. *Monit. Scient.*, 1917, 61, 193—196.

EXAMINATION of an accelerator placed on the market by a German firm before the war, showed it to be dimethylamine dimethylaminodithiocarbamate. The method of preparation of this substance by the formation of dimethylamine by the action of a 4% solution of potassium hydroxide on *p*-nitrosodimethylaniline and its further combination with carbon bisulphide to form the desired product is outlined; the cost of the materials required for these processes is estimated to be about 4.5 fr. per kilo. (pre-war prices). Using 1% of this accelerator in a rubber mixing the duration of the vulcanisation process is stated to be reduced in the proportion of 8:3.—D. F. T.

Rubber compounds for wire and cable insulation. Rubber Age, 1917. *India Rubber J.*, 1917, 54, 412—425.

AFTER indicating the principal mineral fillers, pigments, and organic additions to mixings for wire and cable insulation, particulars are given of a

large number of mixings by way of indicating how a good insulation may be made up. Good results do not, however, depend only upon the use of good materials, since the manner in which the raw rubber is handled and the compounds worked together have also much to do with the success of the operations.—E. W. L.

PATENTS.

Vulcanisable elastic masses suitable for use as rubber substitutes; Production of—E. S. Ali-Cohen. The Hague, Holland. Eng. Pat. 103,824, Jan. 22, 1917. (Appl. No. 1076 of 1917.) Under Int. Conv., Jan. 29, 1916.

AN elastic mass free from sulphur, which can be vulcanised like rubber, and which is not liquid at the temperature of vulcanisation, is prepared by mixing an aluminium, iron, or other earth or heavy metal salt of a higher fatty acid, dissolved or not in a high-boiling hydrocarbon, with a drying oil at 250° C., the drying oil having previously been heated for a considerable time with an oxidising agent such as manganese dioxide. *Example*. One part of aluminium stearate is dissolved in one part of ozokerite, and mixed with 4—10 parts of oxidised linseed oil at 200°—250° C. An elastic mass is produced which can be vulcanised with sulphur or certain compounds of sulphur, and can be mixed with filling materials as used in the rubber industry. When mixed with an appropriate substance, e.g., asphaltum, it forms an electrical insulator suitable for cables, etc.—F. St.

Rubber; Method of vulcanising—R. B. Price. New York, Assignor to Rubber Regenerating Co. U.S. Pat. 1,237,554, Aug. 21, 1917. Date of appl., Dec. 13, 1913.

SHEET rubber is interleaved with homogeneous conducting material, and a current of electricity of suitable intensity is passed through the latter for a length of time sufficient to vulcanise the rubber.—E. W. L.

Rubber or paint; Process of making a filler for—W. B. Rosevear, jun., Detroit, Mich. U.S. Pat. 1,237,704, Aug. 21, 1917. Date of appl., Dec. 9, 1916.

THE precipitate produced in clarifying the juice in sugar manufacture is heated, with free access of air, to a temperature sufficiently high to drive off the moisture and volatile organic matter without discolouring the product, and the latter is used as a filler.—E. W. L.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome [tanning] liquors; Action of neutral salts on—J. A. Wilson and E. J. Kern. J. Amer. Leather Chem. Assoc., 1917, 12, 415—460.

THE amount of alkali necessary to produce a permanent precipitate in a chrome liquor is increased by the addition of certain neutral salts. The authors believe this to be due to the hydration of the ions of the added salts. The water thus bound is, in a sense, removed, and the liquor behaves like one of greater concentration. This view is borne out by experiment, the amount of alkali necessary to start precipitation being larger the greater the degree of hydration of the ions of the added salt.—F. C. T.

Chrome [tanning] liquors; Analysis of one-bath—D. McCandlish. J. Amer. Leather Chem. Assoc., 1917, 12, 440—445.

USED one-bath chrome liquors cannot always be

oxidised readily by sodium peroxide, owing to the presence of soluble protein which in hot acid solution acts as a reducing agent. No difficulties arise, however, if the protein present does not exceed 1.25%. When larger quantities are present, the chromium may be estimated gravimetrically. Another method is to evaporate the liquor to dryness in a platinum basin with a mixture of 60% of magnesia and 40% of sodium carbonate, and subsequently to heat the residue strongly. By this means all chromium compounds are oxidised to chromate. The author urges the importance of determining the point at which chrome liquors begin to give a permanent precipitate on the addition of N/10 alkali (such as borax or sodium carbonate).—P. C. T.

PATENTS.

Oil-tanning; Materials for oiling leather and for —. O. Röhm, Darmstadt, Germany. Eng. Pat. 103,668, Jan. 23, 1917. (Appl. No. 1128 of 1917.) Under Int. Conv., June 16, 1915.

PARTLY sulphonated oils are very suitable for oiling leather and for oil-tanning, provided that when neutralised they are easily soluble in water and do not separate from solution on standing. Castor oil may be sulphonated with 0.5% only of sulphuric acid, which is slowly run into the oil whilst stirring, the temperature being kept at about 40° C. The product is then neutralised. —P. C. T.

Glue leather; Process for the conversion of — into glue and the like. O. Röhm, Darmstadt, Germany. Eng. Pat. 104,181, Feb. 15, 1917. (Appl. No. 1267 of 1917.) Under Int. Conv., Feb. 21, 1916.

THE preliminary extended treatment with lime, followed by washing with hydrochloric acid, used in the conversion of glue-leather into edible gelatin or glue, is replaced by treatment for a few hours with pancreatic or similar enzymes which are capable of splitting up or digesting albumin. Acids, ammonium salts, or other substances capable of neutralising lime or other alkali, or amino-acids or other decomposition products of albumin may be used in addition to the enzymes, if necessary. After the scrap or waste has been subjected to this treatment it is boiled. In treating glue-leather which is slowly attacked by the enzymes, it is advantageous to effect a preliminary swelling with 0.5% caustic soda solution.

Leather waste; Compositions utilising —. J. S. Campbell, London. Eng. Pat. 109,530, Nov. 13, 1916. (Appl. No. 16,227 of 1916.) (See also Eng. Pat. 9370 of 1914; this J., 1915, 624.)

POWDERED leather is boiled for 1½ hrs. with water containing sufficient caustic alkali to saponify fats present. Filling material (e.g., chalk or magnesia), and colouring, preserving, and vulcanisable material may then be added, and the boiling continued for ½ hr. The mass is dried and rolled between heated rollers, together with sulphur or other vulcanising agent. The filling material, etc., may be added during rolling instead of when boiling. The product may be immediately vulcanised, or first made liquid by a solvent, applied to a backing such as canvas, and then vulcanised.—P. C. T.

Plastic masses; Process of making — [from brewery by-products]. E. Krause, Steglitz, and H. Blücher, Leipzig-Gohlis, Germany. U.S. Pat. 1,238,528, Aug. 28, 1917. Date of appl. June 12, 1917.

ALBUMINOUS waste products from the manu-

facture of alcoholic beverages, e.g., the cooler sediment from hopped worts, are treated with formaldehyde, and the resulting mass dried and subjected to heat and pressure. (See also Eng. Pat. 76 of 1911; this J., 1915, 972.) —P. C. T.

Plastic compositions; Manufacture of — [from brewery by-products]. E. Krause, Berlin-Steglitz, and H. Blücher, Leipzig-Gohlis, Germany. Eng. Pat. 106,270, Mar. 6, 1917. (Appl. No. 3311 of 1917.) Under Int. Conv., May 11, 1916.

See U.S. Pat. 1,238,528; preceding.

XVI.—SOILS; FERTILISERS.

Alkali [in soils]; Origin of —. R. Stewart and W. Peterson. J. Agric. Res., 1917, 10, 331—353.

THE natural incrustation on the soils of Utah, Colorado, Wyoming, Montana, Alberta, and parts of Canada contains the sulphates, chlorides, bicarbonates and nitrates of calcium, magnesium, and sodium. Extensive field studies of these areas, undertaken by the authors more particularly in connection with so-called "nitre spots," have given results which lend support to the hypothesis that the "alkali" is derived from the soluble salts pre-existing in the country rock. This rock, rich in alkali, not only contributes to soil formation, but is adjacent to and underneath the agricultural soils in the affected areas. There may not be sufficient alkali salts present in the original soil to prevent crop production, but upon the application of irrigation water the "alkali" salts existing in the country rock are leached out and concentrated in the surface soil. Leaky irrigation canals and the rise of the ground water give greatest and quickest concentration. Enormous deposits of soluble salts exist in the shales and sandstones of the Cretaceous and Tertiary strata of Utah, Colorado, and Wyoming. In certain local areas these salts become concentrated so as to produce native "alkali" or "nitre spots" by the movement of the underground water, without irrigation. Wherever the shale is highly impregnated with the salts, evaporation of the water deposits the "alkali" salts on the surface in the form of an ash-like powder.—E. W. L.

Ammonia and nitrates in the soil; Effect of paraffin on the accumulation of —. L. P. Gainey. J. Agric. Res., 1917, 10, 355—364.

PARAFFIN, whether in the form of the commercial "Parowax," or of a prepared paraffin wax (m.p. 50° C.) or of paraffin oil, is found not only to exercise a strong inhibitory effect upon the accumulation of ammonia and nitrate nitrogen in soils, but also to bring about an actual reduction in the quantity of active nitrogen (nitrate nitrogen plus ammonia nitrogen) present. This is not not only the case when the paraffin is mixed with the soil, but also occurs when a column of soil is surrounded by a layer of paraffin wax, thus vitiating results on soil-fertility obtained by the so-called "paraffin wire basket method." Parallel with the disappearance of active nitrogen there is also disappearance of paraffin and enormous development of saprophytic fungi, and the authors suggest that the paraffin is utilised as a stimulant, or source of carbon and energy, by the fungi, which at the same time consume nitrogen in their metabolism.—E. W. L.

Nitrites and ammonia in diseased plants [e.g., sugar beets]; Presence of—. II. *Relation of oxidases and diastases to the disturbance*. P. A. and M. Bonequet. J. Amer. Chem. Soc., 1917, 39, 2088—2093. (See this J., 1917, 41.)

FURTHER observations have supported the conclusion that in certain diseases of plants nitrogen starvation is caused by the bacterial reduction of nitrates to nitrites and ammonia, after they have been taken up by the roots. The first effect of the reducing organisms is to cause a decrease in the oxidising enzymes, but subsequently there is an increase, especially in the new leaves. Plants affected with nitrogen starvation, due to the action of reducing bacteria, showed a vigorous increase in diastatic activity, the tissues of an abnormal deep green colour being 5 or 6 times more active than normal tissues. Conversely, tissues which were yellowing were sometimes devoid of starch-hydrolysing power. In the case of beets affected with "curly leaf" an increased amount of formaldehyde was found in the juice of the leaves. The tissues richest in diastases were also found to be the most active in the formation and storage of starch. Sugar beets affected with "curly leaf" usually contain much more sugar in the roots than normal beets growing under the same conditions. This is attributable to the increased production of chlorophyll under the stimulus of the reducing bacteria. The increased development of diastases appears to be due to the need of an increased hydrolysis of starch, and subsequent transfer of the product to storage cells in the roots. Plants affected with nitrogen starvation always show a higher percentage of ash than normal plants. The maximum increase was observed in plants which had responded most to the stimulus of the bacteria. The total nitrogen in plants thus affected is always lower than that found in healthy plants. Plants infected with nitrate-reducing bacteria lose ammonia by volatilisation. Thus the loss of from 0.15 to 0.19 gm. of ammonia per sq. m. of leaf surface has been observed during 10 hours' sunshine, whereas normal healthy plants apparently lose no ammonia with their transpiration water. —C. A. M.

Soil sulphur: Divergent effects of lime and magnesia upon the conservation of—. W. H. MacIntire, L. G. Willis, and W. A. Holding. Soil Sci., 1917, 4, 231—237.

PRELIMINARY results of an investigation as to the removal of sulphates from soil by rainfall, in the case of a sandy loam soil from Tennessee River, United States, are given. The soil samples mixed with quantities of lime corresponding to 8, 32, and 100 tons per acre, and equivalent amounts of magnesia, precipitated calcium and magnesium carbonates, and ground limestone, dolomite, and magnesite, were placed on sand beds in tanks and leached naturally with the rainfall between July, 1914, and, July 1916. A duplicate lot with 144 lb. of clay subsoil under the soil sample was also operated. The initial SO_4 in the soil was 0.129 %, and the SO_4 in the rainfall was 121 lb. per acre per annum. It was found that all the sulphur was removed as sulphate. The loss of sulphate was heavier from the tanks containing only the surface soil than from the tanks containing subsoil also. Magnesia and magnesium carbonate were exceptions, in that the results during the second year were higher with the subsoil, and also an equivalent amount of magnesium was removed with the sulphate. The treatment with lime at the 32- and 100-ton rates almost inhibited the removal of sulphate. The natural carbonates caused an increased removal of sulphate when compared with untreated soil, and the removal of sulphate during the second year was less than during the first. It is concluded that a

continued loss of sulphates in the amounts found would effect a speedy and absolute depletion of the initial organic sulphur content of the soil, except in the case of the lime treatment.—J. H. J.

Nitrification: Effects of alkali salts on—. P. E. Brown and E. B. Hitchcock. Soil Sci., 1917, 4, 207—229.

THE purpose of the experiments described was to determine the concentration at which alkali salts became toxic to nitrifying bacteria, with special reference to the alkali soils of Wyoming, United States. It was found that in normal soil nitrification was stimulated by small amounts of sodium chloride, sodium sulphate, magnesium sulphate, and calcium carbonate. With larger amounts, the salts became toxic; sodium chloride at 0.02 %, sodium sulphate at 2 %, and calcium carbonate at 1.5—6 %. In alkali soils nitrification was increased by small amounts of sodium carbonate and bicarbonate and of calcium carbonate, while calcium sulphate had no effect. With larger amounts toxicity was produced by 0.3 % of sodium carbonate and bicarbonate, and by 6 % of calcium carbonate. The addition, however, of the calculated amount of calcium sulphate to the two former salts neutralised their toxicity. With both normal and alkali greenhouse soils similar results were obtained, except that sodium sulphate became toxic much sooner, namely, at 0.5 %. The effects on the crops grown on normal soil under the above conditions were parallel to the effects on nitrification. No crops could be secured on the alkali soil.—J. H. J.

Nitric nitrogen in the soil: Some factors influencing the quantitative determination of—. J. E. Greaves and C. T. Hirst. Soil Sci., 1917, 4, 179—205.

AN account of an investigation into the determination of nitrates in soils, especially in those rich in soluble salts and colloids. A clear soil extract can be obtained by adding a flocculant to the soil-water mixture, shaking, and then allowing to stand. The best flocculants were lime, ferric sulphate, ferric alum, sodium alum, and potassium alum, although with lime the amount of nitrate found in the clear extract was lower than that known to have been present in the soil. A clear solution could also be obtained by filtration through a Pasteur-Chamberland filter and by centrifuging. The amount of water used for making the extract could be varied without detriment within the limits of 5—25 times the weight of soil. A finely powdered soil did not require shaking for more than five minutes in making the extract. A slight loss of nitrate occurred in the soil-water extract on standing, but this was prevented by the addition of anti-septics, of which chloroform proved the best when used in the proportion of 1 in 1000. In testing Ciesch's method of determining nitrates (reduction with iron and sulphuric acid), it was found that none of the salts likely to be present in soil interfered with its accuracy. If urea and glycogen were present, it was necessary to evaporate the alkaline solution to dryness before reduction. The presence of dried blood caused the results to be low. The aluminium reduction method gave low results, and the authors replaced it by an iron reduction method, as follows: An aliquot part of the clear extract is evaporated to a quarter of its volume, after addition of 2 c.c. of a saturated solution of caustic soda; then 50 c.c. of ammonia-free distilled water is added, together with 5 grs. of pure iron and 30 c.c. of sulphuric acid (sp. gr. 1.35). The flask is closed with a two-holed stopper carrying a separatory funnel and a side tube bent to dip

below the surface of water in a beaker. The acid is added slowly, and when the rapid evolution is over the flask is heated to boiling for 10 mins. The water in the beaker is added to the flask before boiling. After boiling, the solution is made alkaline and distilled into standard acid, the excess of acid being determined with lacmoid as indicator.—J. H. J.

Peat; Isolation from — of certain nucleic acid derivatives. W. B. Bottomley. Proc. Roy. Soc., 1917, B, 90, 39–44. (See also Eng. Pat. 105,416 of 1916; this J., 1917, 611.)

AN aqueous extract of "bacterised" peat has a stimulating effect on the growth of *Lemna minor* in water culture and contains purine and pyrimidine bases and phosphoric acid, but no nucleic acid. Hence it was thought that nucleic acid might be present in raw peat. To determine this point, an alkaline extract of raw peat was precipitated with hydrochloric acid, as in the extraction of nucleic acid from soil; but the method proved laborious on account of the large amount of humic acid brought into solution. It was found better to saturate the peat with 1% sodium bicarbonate solution for 24 hrs., which left the humic acid undissolved, and then to express the liquid, to concentrate it in a vacuum to a small volume, and to pour it into absolute alcohol containing sodium acetate and hydrochloric acid. The precipitate was filtered off and dried in a vacuum, and both filtrate and precipitate were examined. The precipitate contained phosphoric acid and gave reactions for carbohydrates, but mild hydrolysis with a mineral acid failed to yield a purine base. The precipitate was heated, therefore, with 25% sulphuric acid in an autoclave at 140° C. for 5 hrs. From the hydrolysed product, silver-purine and silver-pyrimidine precipitates were obtained. The latter was found to contain uracil, and the former adenine. These results proved that the precipitate from the peat contained an adenine-uracil dinucleotide. The examination of the alcoholic filtrate showed the presence of a guanine-cytosine dinucleotide. From these results it is concluded that the nucleic acid of the plants from which the peat was formed, had been decomposed by bacteria or other agencies, during the formation of the peat, into dinucleotides.—J. H. J.

PATENT.

Fertilisers [from refuse, sewage sludge, etc.]. A. D. Furse, Beckenham. Eng. Pat. 109,575, Feb. 14, 1917. (Appl. No. 2184 of 1917.)

HOUSE refuse or sewage cake or a mixture of these is incorporated with 15% to 20% of fish or animal refuse, 15% to 20% of pulverised bones, preferably deglutinised, and 15% to 20% of vegetable refuse containing potash, such as that obtained from beetroot, sugar-cane, tobacco, or banana. If odour is of no consequence the proportion of both fish refuse and bones may be increased. The mixture is disintegrated and then, preferably after treatment with dilute sulphuric acid, left to dry, powdered, and screened.—B. V. S.

XVIII.—FERMENTATION INDUSTRIES.

Sugar-cane juice; Fermentation of —. Kayser. Ann. Falsif., 1917, 10, 296–301.

EXPERIMENTAL fermentations showed that the quality of a rum depends largely on the manner in which the juice is extracted, the method of fermentation, kind of yeast, temperature, etc. The following results were obtained in the analysis of rums prepared under different conditions from various juices (see below); the figures express mgrms. per 100 c.c. of absolute alcohol:—

	A.	B.	C.	D.	E.	F.
Volatile acid	1.43	55.0	138.0	187.0	15.3	32.2
Aldehyde ..	9	57.6	14.8	22.6	52.5	43.0
Furfural	trace	0.35	0.13	0.13	5.7	2.4
Esters	424.0	128.0	45.0	95.0	92.8	42.4
Higher alcohol	30.9	200.0	50.7	33.0	182.0	245.0

Juice A was allowed to ferment spontaneously, the juice being expressed from the cane; B was a thick juice fermented with selected yeasts; C and D, normal juices fermented with selected yeasts; E and F were diffusion juices also fermented with selected yeasts. The temperature of fermentation was 25° C.—W. P. S.

PATENTS.

Beverages; Extract for carbonated —. L. Stein, Newark, N.J., Assignor to J. C. Dehls, Brooklyn, N.Y. U.S. Pat. 1,237,723, Aug. 21, 1917. Date of appl. May 5, 1917.

THE preparation claimed contains the products of the action of proteolytic enzymes, e.g., those of yeast, on a mixture of animal and vegetable protein, together with an acid phosphate. Sugar and flavouring matters may also be added.—J. H. L.

Malt beverage; Unfermented — and process of preparing the same. W. A. Steinmann, Los Angeles, Cal. U.S. Pat. 1,237,724, Aug. 21, 1917. Date of appl. Oct. 21, 1916.

CRUSHED malt containing a substantial amount of insoluble starch is mixed with water at temperatures favourable to peptonisation, so as to obtain

an extract whilst leaving a considerable amount of starch undissolved. This extract may then be saccharified, and afterwards boiled to destroy the diastase.—J. H. L.

Fermented beverages; Process of treating —. J. Schneible, Chicago, Ill. U.S. Pat. 1,238,577, Aug. 28, 1917. Date of appl. Jan. 11, 1916.

FERMENTED beverages containing albuminous matters in solution, are subjected to reduced pressure, e.g., 2–3 lb. per sq. in., at comparatively low temperatures, e.g., 58°–62° C., to volatilise practically the whole of the higher alcohols present, whilst the ethyl alcohol and albuminous matters are retained. The claims also cover the introduction of a current of steam during the treatment, and the exclusion of air before, during, and after the treatment.—J. H. L.

Non-alcoholic, chill-proof beverage; Process of preparing a —. J. Beerhalter, Duluth, Minn. U.S. Pat. 1,210,016, Sept. 11, 1917. Date of appl. Nov. 18, 1914.

IN the preparation of non-alcoholic beverages from malted grain and vegetable flavouring substances, charged with carbon dioxide, a proteolytic enzyme, active in faintly acid media, is added to the wort after cooling. Such an enzyme may be extracted from malt, and remains active in the finished beverage; it prevents the coagulation of proteins and renders the beverage chill-proof and more stable at ordinary temperatures.—J. F. B.

Hops; Drying of —. G. H. Benjamin, New York. Eng. Pat. 109,584, Apr. 4, 1917. (Appl. No. 4878 of 1917.)

SEE U.S. Pat. 1,226,052 of 1917; this J., 1917, 731.

Process of making plastic masses [from brewery by-products]. U. S. Pat. 1,238,528. See XV.

XIXA.—FOODS.

Bread making; Use of calcium gluconate in —. G. A. Le Roy. Comptes rend., 1917, 165, 416.

CALCIUM gluconate can be employed instead of lime water for improving the flavour of bread made from 85% flour as at present in use in France. It is prepared in the usual way by digesting a solution of commercial glucose with milk of lime and filtering. It is more convenient than calcium succrate and lime as it is more soluble. The gluconate should be used in quantity representing 100 grms. of glucose and 50 grms. of lime for each 100 kilos. of flour, and added along with the yeast and salt. This quantity will yield bread containing 1 gm. of glucose and 0.5 gm. of lime per kilo. The gluconate has been found to facilitate rather than retard fermentation.—J. H. L.

Flour and bread; Determination of bran in —. R. Legendre. Ann. Falsif., 1917, 10, 293–296.

To ascertain whether a bread has been prepared from a particular flour, 2 grms. of the flour and 3 grms. of the bread crumb are placed in separate test-tubes, 10 c.c. of water and 10 c.c. of phosphoric acid (sp. gr. 1.514) are added to each tube, and the mixtures are heated at 120° C. in an auto-lave for 1 hour. After cooling, the sediments are collected on a silk sieve (120-mesh), washed with water, alcohol, and ether, and then dried and weighed. The two weights should be equal after allowance has been made for the different quantities

of water present and the different amounts of the flour and bread taken. The moisture content is determined on separate quantities of the flour and bread. For rapid work, it is sufficient to centrifuge the two sediments with water and to note the volumes; when 2 grms. of flour and 3 grms. of bread are taken for the experiment, the volumes of the sediments should be equal.—W. P. S.

Fat in certain milk products; Determination of —. C. K. Francis and D. G. Morgan. Bull. 114, Oklahoma Agric. Expt. Stat. J. Ind. Eng. Chem., 1917, 9, 861–862.

For the determination of fat in ice cream, evaporated milk, malted milk, etc., a modification of the Babcock test is recommended, in which mixtures of glacial acetic acid, nitric and sulphuric acids replace the sulphuric acid. For example, in the case of ice cream, 9 grms. of the sample is treated in a Babcock bottle with 4 to 5 c.c. of a mixture of glacial acetic acid and sulphuric acid (1 : 1), and then, drop by drop, with strong nitric acid until a light yellow colour is produced. The bottle is then immersed for 4 to 5 minutes in boiling water and centrifuged.—C. A. M.

Butter; Effects of feeding cottonseed products on the composition and properties of —. C. M. Eckles and L. S. Palmer. Missouri Agric. Exp. Station Research Bull. No. 27, Dec., 1916, pp. 1–44. Bull. Agric. Intell., 1917, 8, 1021–1022.

THE feeding of cottonseed products causes in general a decrease in the saponification and Reichert-Meissl values, and a rise in the iodine value and the melting point of the butter fat. The butter becomes firmer and frequently has a gummy consistency; it withstands higher temperatures without losing its "body," and acquires a flat, oily flavour and increased keeping quality. These effects are attributed to the cottonseed oil, and depend on the amount of the seeds present in the feed. A factor of great importance, however, is the nature of the raw foodstuffs which form the base of the rations. The effects mentioned are most pronounced when dry roughage (timothy hay, etc.) is fed with the cottonseed products, whilst if a fairly large proportion of corn (maize) silage is fed the effects are more or less neutralised. Small amounts of cottonseed products, fed to cows on fresh pasture, improve the "body" and keeping properties of the butter produced. The effect of feeding cottonseed meal on certain of the constants of butter fat, particularly the Reichert-Meissl and iodine values, may be somewhat modified by continuous feeding, but the effects on the melting point of the fat and the other properties of the butter continue as long as the meal is fed. The authors accordingly deprecate the feeding of large quantities of cottonseed meal, and also the use of the whole seed owing to its high oil-content.—J. H. L.

Silage; Contribution to the bacteriology of —. J. M. Sherman, J. Bacteriol., Baltimore, 1916, 1, 415–451. Bull. Agric. Intell., 1917, 8, 1020–1021.

OBSERVATIONS made on silage during 1915, indicated that an important part in the curing of corn (maize) silage is played by an acid-tolerant, acid-producing organism closely related to the *Bac. bulgaricus* and *B. acidophilus* groups but differing somewhat from the typical members of these groups by its comparatively abundant growth on ordinary laboratory media. The number of bacteria present in silage juices is very great, always more than a "billion" per c.c., and most of them resemble the one referred to

above. These are abundantly present in maize fodder, so that ensilage made from maize is always amply seeded with them.—J. H. L.

Mannitol; Occurrence and significance of — in silage. A. W. Dox and G. P. Plaisance. J. Amer. Chem. Soc., 1917, 39, 2078—2087.

MANNITOL is a normal constituent of corn (maize) silage, eight samples of which contained from 1.47 to 2.51% calculated on the dry substance (28.0 to 38.1%). Sugar cane silage contained 3.30% and sunflower silage 5.61% of mannitol on the dry substance, but none was present in the silage from cow peas or sweet clover. The mannitol is formed from the sucrose in the plants by bacterial reduction. It is produced simultaneously with acetic acid, lactic acid, carbon dioxide, and alcohol, and then partly disappears. By expressing the juice from silage, evaporating it, filtering off the magnesium lactate and adding alcohol to the filtrate until the alcoholic strength was about 75%, 30 grms. of pure mannitol was obtained from 6670 grms. of silage. The expressed residue would be suitable for feeding purposes, whilst the mannitol could be utilised in the manufacture of explosives. It could be readily extracted on a large scale by this method, and would probably be cheaper than glycerol.—C. A. M.

L-Leucine; Occurrence of — in sweet clover silage. G. P. Plaisance. J. Amer. Chem. Soc., 1917, 39, 2087—2088.

SAMPLES of sweet clover silage contained from 0.4 to 1.0% of L-leucine, calculated on the dry material. It could be readily extracted from the dried substance with 95% alcohol.—C. A. M.

[Feeding stuffs]. *By-products from the manufacture of tin plate.* Board of Agric., Ohio, 1917, 7, 65—66. Bull. Agric. Intell., 1917, 8, 1020.

CEREAL middlings (usually wheat) and palm oil are used in the polishing of tin plate. After use the mixture of middlings and oil was, until a few years ago, discarded; but cattle eat it readily and it is now sold in the United States as a feeding stuff, under the name of "Palmo Midds," after treatment to remove pieces of metal. This treatment at first consisted in a simple sifting operation by hand, but a new electro-magnetic process has been found to give better results.—J. H. L.

The Schilde "universal" dryer. Parow. See I. Method for fractionating fats and oils. Seidenberg. See XII.

PATENTS.

Freezing fish and other food substances. N. Dahl, Trondhjem, Norway. Eng. Pat. 109,238, May 31, 1917. (Appl. No. 7785 of 1917.)

FREEZING by means of circulating fluid is so conducted that the direction of flow of the liquid is longitudinal with respect to the fishes or other pieces of food, instead of transverse as hitherto. Export cases containing fish, for example, are preferably placed during refrigeration so that the fish are in a vertical position, the horizontal walls of the cases being provided with one or more openings (which can be closed after refrigeration) to serve as inlets and outlets for the cooling liquid. It is claimed that this facilitates the circulation of the liquid between the fish or pieces of food and produces more rapid and complete refrigeration.—J. H. L.

Wheat; Method of treating [cleaning and sterilising] —. A. C. von Hagen, Kansas City, Mo. U.S. Pat. 1,237,425, Aug. 21, 1917. Date of appl., Sept. 1, 1916.

GRAIN is moistened, e.g., with alkali (lime) and

hypochlorite solution or with the latter alone, and the solution, which may be distributed over the surface of the grain by agitation, is finally forced through the husk by pressure, e.g., air-pressure. Before this last operation the moistened grain may be treated with carbon dioxide.—J. H. L.

Dryer for alimentary paste. P. De Martini, Jamaica, N.Y. U.S. Pat. 1,237,871, Aug. 21, 1917. Date of appl., Nov. 13, 1916.

A MAIN compartment, containing racks for the material to be dried, has means (louvre boards) for controlling the passage of air through its two ends over substantially their whole area, vertical rotary fans between the racks to produce a current of air through the compartment, and further means (transverse partitions with louver boards) for controlling and directing the air current through each rack.—J. H. L.

Sweet potatoes or yams; Food product manufactured from — and process for producing the same. J. H. Williams, Assignor to Williams Co., Greenville, S.C. U.S. Pats. (A) 1,238,371, (B) 1,238,372, and (C) 1,238,373, Aug. 28, 1917. Dates of appl., (A) Sept. 28, 1916, (B) and (C), Nov. 17, 1916; (B) renewed July 26, 1917.

SWEET potatoes are partly dehydrated and then cooked by steaming, and after they have been cooled, peeled, and mixed, flour, salt, and flavouring matters are added as required. The dough is mixed with yeast and allowed to ferment for a considerable time, then worked, mixed with more steamed potatoes, allowed to rise, and baked. The loaves obtained are sliced and passed through a pug-mill and the product is thoroughly dried or toasted. In (A) it is passed through a mill and crushed into nut-like particles for marketing, in (B) it is ground to a flour for culinary purposes, and in (C) it is milled into small particles which are converted into flakes by passing between heavy steel rollers under high pressure, and then toasted.—J. H. L.

Milk-powdering machine. I. J. Felleman, Gridley, Cal. U.S. Pat. 1,239,471, Sept. 11, 1917. Date of appl., Apr. 30, 1917.

THE machine comprises a pair of heated rolls, means for spraying milk thereon, and a carriage centrally beneath the rolls mounted to travel longitudinally thereof, and carrying planer knives which project in opposite directions and engage the rolls. A receptacle moves with the carriage in such a manner that the products discharged by the knives are received by the receptacle, which is automatically emptied at the ends of the travel, at which points also a plunger is automatically moved so as to throw the planer knives into and out of engagement with the roll.—J. F. B.

Rice; Process of treating — and product thereof. M. M. Baumgartner, Freeport, Ill. U.S. Pat. 1,239,555, Sept. 11, 1917. Date of appl., Dec. 13, 1916.

WHOLE rice including the germ and hull is steeped in water and cooked with live steam, while in the hull, to dextrinise the starch and stabilise the fats and proteins; the rice is then dried and parched to produce a product not differing materially in form and bulk from the natural rice, and the hulls are finally removed from the kernels.

—J. F. B.

Casein; Process of drying —. W. M. Brownell, Brooklyn, N.Y., Assignor to A. N. Flood, Newton, Mass., and J. T. Nightingale, Boston, Mass. U.S. Pat. 1,239,766, Sept. 11, 1917. Date of appl., May 1, 1916.

THE curd of wet casein is heated at 135°—180° F.

(57°—82° C.) to form a plastic, sticky, homogeneous mass; the material is formed into small pieces, or into continuous ribbons which are subsequently cut into small pieces; the pieces are immersed in water at a lower temperature than that mentioned above, to render the surface non-adhesive, and then dried with agitation.

—J. F. B.

Flesh of animals of the bovine genus: Process for the preparation of —, J. Balzani, Buenos Aires, Argentina. U.S. Pat. 1,240,165, Sept. 18, 1917. Date of appl. Nov. 1, 1915.

SEE Eng. Pat. 15,559 of 1915; this J., 1916, 1175.

XIXB.—WATER PURIFICATION; SANITATION.

Sewage; Purification of — by aeration in the presence of activated sludge. III. E. Bartow. J. Ind. Eng. Chem., 1917, 9, 845—850. (See this J., 1916, 555.)

A CONTINUOUS-FLOW plant, designed to deal with 200,000 galls. of sewage and sludge, was started in 1916 at the Sewage Experimental Station, University of Illinois. The sewage flows from the grit chamber into the aeration chamber, which is a rectangular concrete tank 17×36½ ft., and 9½ ft. deep. It is divided by longitudinal baffles into 4 compartments through which the sewage flows down sloping sides into a central channel, above which are "filtros" plates. This chamber has a capacity of 36,000 galls., and is capable of aerating 144,000 galls. of sewage during 6 hours. From the aeration chamber the sewage passes to a settling chamber, and thence over a weir, and is either returned to the sewer or discharged into a pond. Air is supplied by a rotary pressure blower with a capacity of 300 cub. ft. per min., and is filtered through cheesecloth stretched over the wire sides of a box. This plant was in continuous use for 3 months, and dealt with 61,000 to 177,600 galls. per day. Approximately 2 cub. ft. of air per gall. of sewage was required to obtain a stable effluent. Comparative tests with different methods of diffusing the air in tanks operated on the fill and draw system showed that "filtros" plates gave better aeration results than perforated pipes, but little or no difference could be observed between the action of coarse or fine grades of plates. The best method of separating water from the sludge was by centrifuging it in a basket type of centrifugal machine and in a modified cream separator, working at a speed of 1500 r.p.m. Under these conditions sludge containing 97.5% moisture yielded sludge cakes with 85 to 86% moisture. A large (10 in.) machine would be capable of dealing with the sludge from 2,000,000 galls. of sewage per day, producing sludge cake in a condition suitable for a drying plant. A drying test applied to 220 lb. of 88% sludge cake showed that the method was practicable.—C. A. M.

Quassia extract as a contact insecticide. N. E. McIndoo and A. F. Sievers. J. Agric. Res., 1917, 10, 197—531.

THE authors describe numerous experiments to determine the efficiency of various extracts of Jamaica quassia wood and the effect of these extracts upon aphids. Medium-sized quassia chips soaked for 2 hours in water yielded 60% of their total soluble matter, and during a second extraction, 15%. Extraction for 24 hours did not increase the yield. The first extract was slightly more effective than the second in killing aphids. If the chips are boiled for 4 hours the yield of

extract is half as much again. The yield of extract is greater, the larger the volume of water used: 3 grms. of chips yielded one-third more extract to 3 litres of water than to a quarter litre. The solubility of commercial quassia powder is 1 in 3000 of water, and 3—5 times as much in very dilute alkali and soap solutions. In testing the various extracts obtained upon aphids, it was found that soap solution extract, prepared at ordinary temperature, was the most effective and economical. Commercial quassia powder contains quassol, an inert and tasteless substance, and quassia, an effective insecticide and intensely bitter. Exhalations from quassia powder killed aphids, as also did the powder itself when dusted on them, whereas quassia powder and chips were ineffective. Quassia and quassia spray solutions kill aphids when applied sufficiently strong, the solutions containing soap being the most effective. The spray is breathed into the spiracles of the insects and reaches the nerve tissue where it slowly affects the nerve cells, causing a state of coma. The general conclusion is that quassia extracts can never become general insecticides owing to the poor insecticidal properties of quassia. The formula which yielded the most effective extract was 22 lb. of quassia chips soaked in 100 galls. of fish-oil soap solution for 24 hours. This extract was effective on two out of six species of aphids. Nicotine sulphate is a more reliable insecticide.—J. H. J.

Volatility of organic compounds as an index of the toxicity of the vapours to insects. W. Moore. J. Agric. Res., 1917, 10, 365—371. (See also this J., 1917, 939.)

THE toxicity towards the house-fly of a large number of organic compounds, including representatives of the following classes, was determined: esters, acids, ethers, hydroxy compounds, aldehydes, ketones; halogen, sulphur, and nitrogen derivatives; terpenes or terpene derivatives, and alkaloids. In general, toxicity was found to be closely correlated with volatility; decreasing volatility is accompanied by increased toxicity up to a certain point, but compounds with boiling-points of 225° C. to 250° C. are usually so slightly volatile that they produce death only after very long exposures. The explanation of the main result obtained by the author is that the vapour of the compound condenses on the finer divisions of the trachea of the insect. Readily volatile compounds will evaporate and rapidly pass out of the insect, whereas less volatile ones will remain, penetrating the tissues and producing the poisonous effects resulting in death.—E. W. L.

Ultra-violet radiation; Germicidal action of —, and its correlation with selective absorption. C. H. Browning and S. Russ. Proc. Roy. Soc., 1917, B, 90, 33—38.

IN the experiments a tungsten lamp and a quartz spectrometer, giving wave lengths of 7000—2100 Angström units, were used. A glass plate coated with nutrient agar was painted with an emulsion of *Staphylococcus pyogenes aureus*, and a narrow strip of the plate was exposed to the rays from the lamp for 6, 12, or 24 mins. The plate was then incubated. It was found that there was a germicidal action on that part of the strip exposed to rays of wave lengths 2910—2380 units. The longer exposures only very slightly increased the range of germicidal action. Exposures of 3½ hrs. gave a sharp line of demarcation at 2960 units; the other limit was 2150 units. Plates of other organisms were exposed to the rays, and the range of action was found to be nearly the same, although there were small and definite differences in each

case. Emulsions of the organisms were also exposed to the rays and photographs of the radiations transmitted were taken. It was found that absorption of the rays took place over the same range that gave the germicidal action.—J. H. J.

PATENTS.

Gas [hydrogen cyanide for fumigating]; Apparatus for generating —. C. J. Marvin, Los Angeles, Cal., U.S.A. Eng. Pat. 108,889, Aug. 23, 1916. (Appl. No. 11,973 of 1916.)

A PORTABLE apparatus specially adapted to the generation of hydrogen cyanide for fumigating trees, etc.—J. H. L.

Refuse-furnace. E. Kidwell, Washington, D.C., Assignor to Waste Utilities Co. of Delaware, New York. U.S. Pat. 1,239,403, Sept. 1, 1917. Date of appl., Nov. 6, 1912.

THE furnace has a main grate with a non-perforated bottom, and a fore-grate situated at a lower level and arranged to receive slagged material from the main grate. A wall separates the two grates; and a power-actuated pusher passes through a hole in the wall for the purpose of removing slagged material from the fore-grate and out of the furnace. The two grates are provided with separate air supplies and the main grate may be provided with an air jacket. In this case the pusher operates through the air jacket.—J. H. J.

Water; Purification of —. C. P. Hoover, Columbus, Ohio, U.S.A. Eng. Pat. 107,967, June 22, 1917. (Appl. No. 8988 of 1917.) Under Int. Conv., July 11, 1916.

SEE U.S. Pat. 1,197,123 of 1916; this J., 1916, 1079.

Fertilisers [from refuse, sewage sludge, etc.]. Eng. Pat. 109,575. See XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; A theory of the mechanism of the phytochemical synthesis of certain —. R. Robinson. Chem. Soc. Trans., 1917, 111, 876—899.

SYNTHESIS of alkaloid skeletons may be carried out by building up from simple compounds such as formaldehyde, ammonia, simple amino-acids as arginine and lysine, and degradation products of carbohydrates, typified chiefly by acetonedicarboxylic acid. Further modifications are usually made by means of oxidation or reduction and by elimination of water with the formation of an aromatic nucleus or occasionally of an ethylene derivative. Several schemes are discussed for the synthetic formation of the base groups of different classes of alkaloids. Linking of carbon to carbon is traced to two processes only: the aldol condensation and the very similar condensation of carbinolamines, resulting from the combination of an aldehyde or ketone and ammonia or an amine, and containing the group $:C(OH)N:$, with substances containing the group $:CH.CO:$. The reactive acetone derivative which undergoes condensation with formaldehyde and ammonia has been formulated in the majority of cases as acetonedicarboxylic acid, but in other cases, as a starting point both for quinoline and isoquinoline bases, it has been found convenient to assume the intervention of acetylglcollic aldehyde, which may be derived from a pentose or methylpentose by loss of water and oxidation. Substances

accompanying quinine and cinchonine in cinchona bark have been found to be suitable starting points for a synthesis of the quinoline half of these alkaloids.—J. F. B.

Carbamides; Constitution of —. IV. Mechanism of the interaction of urea and nitrous acid. E. A. Werner. Chem. Soc. Trans., 1917, 111, 863—876.

THE reaction between urea and nitrous acid with evolution of carbon dioxide and nitrogen is not practically available for the determination of urea but is useful for the estimation of nitrous acid. As a matter of fact, no reaction takes place between urea and pure nitrous acid in aqueous solution: even in presence of a weak acid, such as acetic acid, the reaction is very slow and only apparent at high concentrations. On the other hand, the presence of a strong acid, such as hydrochloric or nitric acid in dilute solutions, is sufficient to produce a brisk evolution of gas, but the volume of nitrogen evolved is not a direct measure of the quantity of urea decomposed as calculated on the usual equation, the amount of urea decomposed being much greater than that indicated by the evolved nitrogen. Only when the urea is present in considerable excess is the volume of nitrogen approximately equivalent to the amount of nitrous acid decomposed. The volume ratio of carbon dioxide to nitrogen (1:2) required by the equation is never obtained, the amount of carbon dioxide being always greater; the composition of the gases is liable to variation with small changes in concentration. The above apparent anomalies are explained by the fact that urea is not carbamide, as was commonly supposed, but a derivative of cyanic acid, $HN:C\overset{\overset{NH}{|}}{O}$; in presence of a strong

acid a salt, $NH:C(OH)NH_2.HX$, is formed, and an amino group is thus rendered open to attack by nitrous acid. The first stage of the reaction takes place according to the equation

The cyanic acid is decomposed in two ways as fast as it is generated. It is hydrolysed, thus: $HNCO + H_2O = NH_3 + CO_2$ and it is directly attacked by nitrous acid, thus: $HNCO + HNO_2 = CO_2 + N_2 + H_2O$. The two last reactions proceed simultaneously in variable proportions according to the conditions of concentration, acidity, etc., prevailing. With an excess of urea present at the outset, a low concentration of nitrous acid, and the presence of an excess of mineral acid to combine with the ammonia, the reaction may be practically confined to equimolecular proportions of urea and nitrous acid, instead of 1:2 mols. as required by the supposed carbamide structure of urea.—J. F. B.

Methylation by means of formaldehyde. I. Mechanism of the interaction of formaldehyde and ammonium chloride. Preparation of methylamine and dimethylamine. E. A. Werner. Chem. Soc. Trans. 1917, 111, 841—853.

THE products of the action of formaldehyde on ammonium chloride comprise carbon dioxide, a volatile liquid, and the hydrochlorides of methylamine and dimethylamine. The volatile liquid distils between 50° and 101° C. The distillation residue contains methylamine and dimethylamine hydrochlorides, and the reaction may be used for the preparation of these substances. The mechanism of the reaction between formaldehyde and ammonium chloride depends on the formation at the first stage of methylene-imine, the hydrochloride of which, $CH_2:NH(HCl)$, undergoes hydrogenation at the expense of the formaldehyde, which yields formic acid, part of which is esterified

and part oxidised to carbon dioxide and water, thus:

The formation of dimethylamine from monomethylamine follows an analogous course through the intermediary production of methylenemethylamine. Trimethylamine is not formed in the main reaction but some may be produced by prolonged heating of the final mother liquors. As a preparatory method the following procedure gives satisfactory yields: 250 grms. of ammonium chloride and 500 grms. of commercial 40% "formalin" solution are heated slowly in a distillation flask up to 104° C. until no more liquid distils over; the operation requires about 1½ hours. The distillate (110 grms.) has the composition: methyl formate, 30.0; methylal, 31.6; free formic acid, 1.6; water, 24.8%. On cooling the residue in the flask, ammonium chloride (62 grms.) crystallises out; the filtrate is concentrated at 100° C. to about half its bulk and a further crop of ammonium chloride (19 grms.) is recovered. Ammonium chloride is very sparingly soluble in a concentrated solution of methylamine hydrochloride. Evaporation of the filtrate is then continued until a crystalline scum forms at the surface of the hot liquid and the monomethylamine salt (96 grms.) crystallises out on cooling; a second crop (18 grms.) is obtained by further evaporation. The filtrate is evaporated as far as possible at 100° C., left for 24 hours *in vacuo* over sodium hydroxide, and the semi-solid residue digested with chloroform, in which the dimethylamine salt is soluble. The total yield of monomethylamine salt is 128 grms. For the preparation of dimethylamine hydrochloride, 200 grms. of ammonium chloride and 400 grms. of "formalin" are heated at 104° C. as before; the excess of ammonium chloride which separates on cooling is filtered off and the filtrate is again heated with 300 grms. of "formalin" in a distillation flask up to 115° C. until no more liquid distils. The distillate this time contains a much larger proportion of water. The fractional crystallisation of the products is carried out as before but the final liquor is evaporated at 120° C. Extraction of the dried mass with chloroform yields 122 grms. of dimethylamine salt.—J. F. B.

Organic compounds; Removal of nitric acid from solutions of —. P. A. Levene and G. M. Meyer. *J. Biol. Chem.*, 1917, **31**, 599—601.

In the preparation of certain organic compounds it is frequently necessary to separate nitric acid from solutions without acting deleteriously on the organic compounds present. The removal of nitric acid from neutral aqueous solution by reduction by means of zinc dust or a zinc-copper couple is never complete, but with aluminium amalgam the reduction easily proceeds to completion. The procedure is to neutralise the solution by means of barium hydroxide and then to add 2 grms. of freshly prepared aluminium amalgam for each gram of nitric acid. After standing for 8 hours or overnight, during which time the solution is continuously aerated, the liquid is filtered and a slight excess of barium hydroxide added; ammonia is removed by repeated evaporation under reduced pressure, and the excess of baryta is then quantitatively precipitated. Under these conditions only about 40% of the nitric acid is converted into ammonia, the remainder probably escaping in the form of lower oxides of nitrogen.—D. F. T.

Volatile acids; Possibilities and limitations of the Duclaux method of determining —. L. J. Gillespie and E. H. Walters. *J. Amer. Chem. Soc.*, 1917, **39**, 2027—2055. (See also this J., 1917, 236, 520, 568.)

TEST determinations of the volatile acids in

known mixtures by Duclaux's method (*Ann. chim. phys.*, 1874, [5], **2**, 289) have shown that for mixtures of three acids quantitative results may be obtained by either algebraic or graphic methods of calculation, but that in the case of mixtures of four acids the errors are, as a rule, too great. These errors are not proportional to the quantities of acids, and when four or more acids are present the mixture must be fractionated, before applying the method, into two mixtures each containing substantially only three acids. The methods of calculation do not depend upon the laws which govern the rates of distillation of aqueous solutions of pure acids, and may therefore be applied to distillations made in various ways, provided that the distillations of pure acids and of mixtures are carried out in the same way (see also this J., 1908, 897).—C. Opium: Process for extracting alkaloids from —. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 109,468, Sept. 8, 1916. (Appl. No. 12,747 of 1916.)

ONE part of powdered opium is mixed with about two parts of concentrated formic acid (95—100%) at the ordinary temperature, and the mixture stirred until solution is complete with the exception of some fibrous and foreign matter; the mass is then stirred into about twenty parts of water, and the insoluble substances (resin, etc.) filtered off and washed until free from alkaloids. The alkaloids are then separated from the aqueous solution by precipitation or extraction.—L. A. C.

Vitamine preparations; Process for obtaining —. Ges. für Chem. Ind. in Basel, Switzerland. Eng. Pat. 103,294, Jan. 4, 1917. (Appl. No. 224 of 1917.) Under Int. Conv., Jan. 7, 1916.

SEE U.S. Pat. 1,235,198 of 1917; this J., 1917, 1064.

Lipoid-like blood-clotting substance, and a process of making same. A. Fonio, Langnau, and W. Föhrenbach, Basle, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,240,694, Sept. 18, 1917. Date of appl., June 8, 1915.

SEE Eng. Pat. 11,215 of 1915; this J., 1916, 72.

Polishing explosive powder: Process of and apparatus for —. F. I. du Pont. Assignor to Ball Grain Explosives Co., Wilmington, Del. U.S. Pat. 1,239,368, Sept. 4, 1917. Date of appl., July 28, 1915.

GRANULAR explosive powder is fed into one end of a horizontal rotating tube, the length of which is at least fourteen times the depth of the layer of powder in the tube. The powder is propelled along the tube by a short helix at the inlet end, and means are provided at the outlet end to restrict the discharge and regulate the depth. —W. F. F.

Explosive powder; Process for finishing —. F. du Pont, Assignor to Ball Grain Explosives Co., Wilmington, Del. U.S. Pat. 1,240,549, Sept. 18, 1917. Date of appl., July 28, 1915.

GRANULAR explosive powder is passed through an apparatus in which it is continuously moved forward and also given a transverse rolling motion. A polishing material is continuously added to the moving powder, and a blast of hot air is directed over the powder in a direction opposite to the movement of the grains so as to smooth them, blow away the dust, and then polish the grains. —F. Sp.

Chlorate explosive of the Sprengel class. W. C. Wain. North Sydney, N.S.W. U.S. Pat. 1,240,272, Sept. 18, 1917. Date of appl., Mar. 19, 1915.

A SATURATING liquid for chlorate explosives of the Sprengel class is produced by dissolving 20 vols. of castor oil and 20 vols. of raw linseed oil in 320 vols. of petroleum, and treating the solution with 10 vols. of fuming nitric acid (sp. gr. 1.5) so as to nitrate the oils without leaving free acid present. The product is a brown transparent liquid having a specific gravity of approximately 0.816 and a rate of diffusion approximately double that of nitrobenzene.—F. Sp.

Trinitrotoluene; Process for the manufacture of —. F. Quartieri, Milan, Italy. U.S. Pat. 1,241,017, Sep. 25, 1917. Date of appl., Aug. 31, 1914.

SEE Eng. Pat. 19,566 of 1914; this J., 1915, 1118.

XXIII.—ANALYSIS.

Corks used in Soxhlet and other extraction apparatus; Treatment of —. T. J. Ward. Analyst, 1917. 42, 326—327.

THE difficulties arising from the porosity of cork and the solubility of certain of its constituents, when used in extraction apparatus, may be overcome by heating the corks in a gelatin solution (see below) at 100° C. for two hours, wiping and drying them, and then using them in a Soxhlet extractor for an hour. The gelatin solution is prepared by soaking gelatin in cold water for five or six hours, pouring off the water, melting the gelatin, and adding $\frac{1}{4}$ vol. of glycerol and 2 vols. of water. Corks treated thus must not be used with solvents in the vapour of which water and glycerol are readily soluble.

Carbon and hydrogen; Simplified micro-combustion method for the determination of —. L. E. Wise. J. Amer. Chem. Soc., 1917, 39, 2055—2068.

THE method devised by Pregl (Abderhalden's Handbuch der Biochem. Arbeitsmethoden [ii.], 5, 1307) has been simplified as follows:—The combustion tube consists of a hard glass tube 1.5 cm. in diam. (with a bore of 1.2 cm.) and 38 cm. in length, and at about 4 cm. from the end is drawn out to about 3 mm. in diam., whilst the other end of the tube is fitted with a rubber cork through which passes a capillary tube. The tube is packed successively with a plug of glass wool, a 2.5 cm. layer of asbestos treated with cupric oxide, containing a few lengths of cupric oxide wire; a 0.5 cm. layer of asbestos; a 1.5 cm. layer of platinised asbestos; 0.5 cm. of plain asbestos; 3.5 cm. of asbestos treated with cupric oxide and containing cupric oxide wire; 0.5 cm. of plain asbestos; 1.5 cm. of platinised asbestos; and finally 0.5 cm. of plain asbestos. From 11 to 22 mgrms. of the substance is used for the combustion, which is effected in a flat platinum boat. In place of the usual carbon dioxide absorption tube, a tube with a ground-in joint is used, and soda-lime replaces caustic potash as absorbent. For drying the air admitted to the apparatus a train of absorption vessels charged respectively with sulphuric acid, soda-lime, and calcium chloride saturated with carbon dioxide is used. It is advisable to make "blank" determinations under the same conditions as the actual combustion, and to correct the amounts of hydrogen from the results. In some cases the uncorrected values are 0.1 to 0.15% higher than the corresponding corrected values. The use of a micro-balance would increase the accuracy of the carbon determinations, but by the use of the larger quantities mentioned above the results agree well with those obtained by the ordinary methods of combustion on a larger scale—C. A. M.

Halogens in organic compounds; Method for the determination of —. J. F. Lemp and H. J. Broderson. J. Amer. Chem. Soc., 1917, 39, 2069—2074.

ABOUT 10 grms. of sodium peroxide is thoroughly mixed with 1 to 1.5 gm. of finely ground potassium nitrate in the fusion cup of a Parr's sulphur bomb (see this J., 1908, 594). From 0.4 to 0.45 gm. of finely powdered benzoic acid or sucrose is then added, the mass again thoroughly mixed, and finally 0.2 to 0.25 gm. of the finely-ground organic compound is introduced, and the whole thoroughly mixed, care being taken to prevent spontaneous ignition. In the case of volatile liquids 0.2 gm. of the sample is weighed in a small sealed bulb of thin glass, which is broken after

the bomb has been screwed down. Ignition is effected by heating the bomb in the hottest part of a Bunsen flame, the heating being continued until at least a fourth of the cup is at a red heat. The bomb is cooled under a water-tap, the tap opened, and the cup placed in 200 c.c. of hot water, the beaker being meanwhile covered with a watch glass. After decomposition of the sodium peroxide, the liquid is acidified with nitric acid, boiled for a few mins., cooled, treated with a measured excess of $N/10$ silver nitrate solution, and again cooled, and the excess of silver titrated with standard thiocyanate solution. In the case of bromine and iodine compounds, it was found that a loss of halogen, especially iodine, might occur upon boiling the acidified solution. To obviate this an excess of silver nitrate is added to the alkaline solution, which is then digested for 15 mins. to insure complete precipitation of the silver halide, and the solution may then be acidified with nitric acid, without any loss of halogens. The addition of compounds rich in carbon and hydrogen is advisable in all cases to insure a thorough and uniform fusion. The addition of a reducing agent to the hot acidified solution containing the precipitated silver halide causes rapid and complete reduction of any oxy-acid of bromine or iodine, with the precipitation of silver bromide or iodide. Hydrazine sulphate was found to be the most suitable reagent for this purpose.—C. A. M.

Silver in organic compounds; Determination of —. H. J. Lucas and A. R. Kemp. J. Amer. Chem. Soc., 1917, 39, 2074—2078.

The method depends upon the interaction of solutions of alkali cyanides and silver salts to form the soluble argenticyanide compound and the alkali salt of the acid, as in the equation:—

The silver in the cyanide solution may be determined by precipitation as metallic silver or as an insoluble salt, such as the sulphide, as in the following method:—About 0.3 gm. of the organic compound is warmed with a quantity of $N/4$ sodium cyanide solution two or three drops in excess of the theoretical amount, and the solution treated with 10 c.c. of $N/1$ sodium hydroxide solution, and diluted to 300 c.c. About 25 c.c. of $N/4$ sodium sulphide solution in excess of that required for complete precipitation of the silver is then slowly added, with constant stirring, and the solution heated to 60°C ., and stirred until the silver sulphide has coagulated. The precipitate is collected in a Gooch crucible, washed with water, alcohol, and ether, dried for 30 mins. at 100° to 110°C ., and weighed, the heating being repeated at intervals of 15 mins. until the weight is constant. The method is applicable to all silver salts which are soluble in alkali cyanide solutions. Of the compounds tried the only one yet found to be insoluble in $N/4$ sodium cyanide solution was the silver salt of diazoaminobenzene.—C. A. M.

PATENT.

Analytical pipettes. P. E. Spielmann, London. Eng. Pat. 109,753, Apr. 30, 1917. (Appl. No. 6107 of 1917.)

AN analytical pipette is provided with a tap, the barrel of which opens above into a suction tube, and into an opening to the atmosphere which may be in the form of a cup, and below into the pipette proper and into a draining tube. The key of the tap is so grooved or drilled that the suction tube may be connected with the pipette while the latter is being filled. By turning the tap through 90° , the suction tube is brought into connection with the draining tube, so that any excess of liquid drawn into the suction tube may be drained off. By turning the tap again through 90° , the pipette is brought into connection with the atmosphere through the small cup, and delivers its contents. The pipette may be washed by filling the cup with water and allowing it to run through the pipette.—F. Sp.

Books Received.

NATIONAL PHYSICAL LABORATORY. COLLECTED RESEARCHES. Vol. XIII. 1916. Harrison & Sons, St. Martin's Lane, London, W.C. 299 pages. Price 20s.

THIS volume contains seventeen papers by members of the staff of the Laboratory, including the following: "On obtaining and maintaining a bright hydrogen spectrum, with special reference to the 4341 line," by J. Guild. "Notes on the analysis of aluminium and its alloys," by W. H. Withey (this J., 1916, 472). "The constitution of the alloys of copper with tin," by J. L. Haughton (this J., 1915, 358). "The choice of glass for cemented objectives," by T. Smith (a mathematical treatment of the subject). "Report on the tests of fuel oils, carried out for the Royal Commission on Oil Fuel, June, 1914. Part I. By J. R. Pannell. Part II. By W. F. Higgins (an abstract of this Report will appear later).

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council desires to remind intending competitors for the Cross and Bevan prize that Essays must be received at the offices of the Society before the close of the present year.

The Essay prize is open to all members of the Society who are British subjects. The Research Grant is limited to competitors under 25 years of age at the time of sending in the essay.

Full particulars were published in the issues of the Journal for 15th January and 15th and 28th February, 1917.

THE OIL SPLITTING ORDER, 1917.

Under an Order entitled as above, which is dated 9th November, no person may, after 12th November, split (otherwise than in the due course of manufacture into soap) any of the oils specified below, or any of the acid oils arising from refining any of such oils into their component parts of fatty acid and glycerine, except under and in accordance with the terms of a licence issued by or under the authority of the Food Controller.

The following are the oils specified:—Coconut oil, cotton oil, gingly (sesamé) seed oil, groundnut oil, soya oil, kapok-seed oil, niger-seed oil, palm-kernel oil, rape-seed oil.

IMPORTATION OF RESIN FROM FRANCE.

The French Government have decided to allow the export to the United Kingdom of a limited quantity of resin for commercial purposes, provided that the applications for export licences are supported by the British Government. In this connection importers of resin from France are invited to furnish to the Assistant Secretary, Commercial Department, Board of Trade, Gwydyr House, Whitehall, London, S.W.1, not later than 28th November, a statutory declaration setting out the respective quantities of (a) light resin (*colophane*) and (b) dark resin (*brai*) which they imported from France in 1916, and to communicate with the Department in regard to their future requirements.

AMMONITE AS A PERMITTED EXPLOSIVE.

The Home Secretary has given notice that, on 5th November, 1917, he made an Order under Section 61 of the Coal Mines Act, 1911, entitled "The Explosives in Coal Mines Order of the 5th November, 1917." The effect of the Order is to add the explosive ammonite to the permitted explosives named and defined in the First Schedule to the Explosives in Coal Mines Order of 1st September, 1913.

ALCOHOL FROM POTATOES.

Preliminary tests having proved satisfactory, the Food Production Department has arranged for an extensive experiment in the making of commercial alcohol from damaged or undersized potatoes at a distillery in Scotland.

VEGETABLE DRYING.

Preparations are being made by the Food Production Department for installing vegetable drying plant in Selby, Pershore, Formby, Cheltenham, and Kidderminster.

THE NITROGEN PROBLEM (*see page 1196*).

London Section.

Meeting held at Burlington House on Monday, November 5th, 1917.

DR. CHARLES A. KEANE IN THE CHAIR.

The CHAIRMAN referred to the great loss the Section had sustained in the death, on October 24th, of Mr. George T. Holloway. Mr. Holloway was Chairman of the Section in 1912-13 and was Vice-Chairman in 1911-12 and 1913-14. A vote of condolence passed by the Committee was confirmed by the meeting.

PATENT LAW IN RELATION TO BRITISH CHEMICAL INDUSTRY.

BY DR. F. W. HAY.

The object of this paper is not merely to criticise and point out certain deficiencies of our patent system, but rather to submit certain data for discussion and to establish with the support of this Society a programme of reconstruction that after mature consideration might be found to encompass the requirements of chemical industry.

It is well known that Great Britain more than most countries depends to a large extent on its industries for its very existence. It will hardly be denied, moreover, that no industry can maintain its reputation and commercial success in the markets of the world without constant improvement; it therefore in turn depends upon the ingenuity and inventive activity of the people who carry it on. In view of these circumstances it is undoubtedly of primary importance to the nation that the inventive talent of the people should be encouraged in the fullest possible measure and the question whether the interests of inventors and those of manufacturers receive the support they deserve under the present system of patent legislation therefore appears well worthy of careful investigation.

The advisability of having a patent system of any description for the protection of inventions has sometimes been questioned. The opinion has even been expressed that patents are a hindrance to the free development of trade. There can be little doubt, however, that patents have on the whole been a very great stimulant to industrial development and that a reward of some kind must evidently be given. No chemist or engineer can be expected to burn his midnight oil and apply his best efforts in the pursuit of some new process or ingenious construction, if after months or years of toil and labour, disappointment and renewed effort, he eventually gets no reward whatever for the invention he may have conceived; and I am not aware that any system for the encouragement of invention has been found that is as equitable as that of granting a limited period of protection by means of Letters Patent, for if the invention turns out to be useless the public is at no expense. I may be allowed to adduce two opinions on this

subject that are of particular interest. Herbert Spencer says in his "Social Statics": "They fall into serious error who suppose that the exclusive right assumed by a discoverer is something taken from the public. He who in any way increases the power of production is deemed by all to be a general benefactor, who gives rather than takes. The successful inventor makes a further conquest over nature, by him the laws of matter are rendered more subservient to mankind," etc. A no less eminent authority on political economy, John Stuart Mill, expresses himself as follows: "The condemnation of monopolies ought not to extend to the patents by which the originator of an improved process is allowed to enjoy for a limited period the exclusive privilege of using his own improvement. This is not making the necessity dear for his benefit, but merely postponing a part of the increased cheapness, which the public owes to the inventor, in order to compensate and reward him for the service. That he ought to be both compensated and rewarded will not be denied, and also that, if all were at once allowed to avail themselves of his ingenuity, without having shared the labours or expense which he had to incur in bringing his idea into practical shape, either such expenses and labours would be undergone by nobody except very opulent and very public-spirited persons, or the State must put a value on the service rendered by an inventor and make him a pecuniary grant. This has been done in some instances and may be done without inconvenience in cases of very conspicuous public benefit, but in general an exclusive privilege of temporary duration is preferable, because it leaves nothing to anyone's discretion, because the reward conferred by it depends upon the invention being found useful, and the greater the usefulness the greater the reward, and because it is paid by the very persons to whom the service is rendered—the consumers of the commodity. I have seen with alarm several recent attempts, in quarters carrying some authority, to impugn the principle of patents altogether—attempts which, if practically successful, would enthrone free stealing under the prostituted name of free trade, and make the men of brains still more than at present the needy retainers and dependents of the men of money-bags."

We have a pretty highly developed patent system in this country. It is by far the oldest system of its kind and dates back to the Statute of Monopolies of 1623. This Statute was enacted under the reign of James I. and saved out of the abolition of the vast number of monopolies that were granted at that time as the result of corruption and which included many of the ordinary necessities of life, such as glass, paper, salt, potashes, iron, lead, tin, etc., those monopolies only that were granted in the form of letters patent for inventions. A very interesting account of the history of the Statute of Monopolies is given in one of the works of J. W. Gordon, K.C., entitled "Monopolies by Patents," to which I must refer for further particulars.

In its fundamental conceptions, as revealed in the Statute, our patent law has been incorporated in the patent codes of almost all other countries, the oldest of which date back about a hundred years, and it cannot be denied that even at the present time the governing principle of our patent law is still on a sound basis. This principle provides that patents should be granted for the introduction of any manner of new manufacture within this realm, so as to promote the industrial development of the country. The new manufacture was supposed to be taught by the inventor to his apprentices during the period of protection granted and thereby made available for subsequent public use. By the Act of 1852 it then became necessary to supply a specification of the invention

when applying for a patent and this specification was intended to enable the public to make use of the invention after the expiration of the patent. The specification afterwards came to be looked upon as the consideration of the grant to the obscurity of the earlier view that a patent was granted for actually setting up a new manufacture within the realm. This state of affairs subsisted until it was corrected to some extent by the Act of 1883, which provided that compulsory licences should be given whenever the patentee neglected to work his invention. In order further to prevent the obstructive use of patents, particularly on the part of foreigners, who instead of working their inventions in this country generally preferred to import the finished article to the detriment of our own industry, Mr. Lloyd George finally introduced the Patents and Designs Act of 1907, which contains provisions for compulsory working in addition to various other enactments. I have still to add to the above brief enumeration of our patent laws the Act of 1902, which instituted a system of preliminary examination as to novelty, based on a search among the English patents issued during the last fifty years.

The Patents and Designs Act of 1907, which consolidates all previous legislation and now governs the law and procedure in regard to patents, says in Sect. 1: "An application for a patent may be made by any person who claims to be the true and first inventor of an *invention*," and towards the end of the Act, in Sect. 93, we find the word *invention* defined as follows: "*Invention means any manner of new manufacture the subject of letters patent and grant of privilege within Sect. 6 of the Statute of Monopolies.*" This Sect. 6 of the Statute saved the granting of letters patent to inventors in the following words: "Provided also that any declaration before mentioned shall not extend to any letters patent and grants of privilege, for the term of fourteen years or under, hereafter to be made of the sole working or making of any manner of new manufactures within this Realm to the true and first inventor and inventors of such manufactures which others at the time of making such letters patents and grants shall not use, so as also they be not contrary to the law or mischievous to the State by raising prices of commodities at home, or hurt of trade or generally inconvenient."

We see therefore that in order to comply with the law and be what we call a valid patent a letters patent must cover an invention, that is to say some manner of new manufacture. This is the law and consequently the attitude of the courts with regard to patents.

The next question that presents itself may be put as follows. Do we deliver patents for inventions, i.e., for some new manufacture? And the answer is: We do so sometimes but not usually. All we do is prescribed in Sect. 7 of the Act of 1907 which says: "Where an application for a patent has been left the examiner shall in addition to the other inquiries which he is directed to make by this Act (i.e., enquiries relating to form), make a further investigation for the purpose of ascertaining whether the invention claimed has been wholly or in part claimed or described in any specification published before the date of application and left pursuant to any application for a patent made in the United Kingdom within fifty years next before the date of application." In other words, the Patent Office examines whether the applicant's invention is disclosed in any of the prior British patents of the last 50 years and if this is not or only partly the case the patent asked for is delivered, a reference to one or more of these prior British patents being sometimes required in the specification issued by way of notice to the public.

This is no doubt a step in the right direction, but it is not enough. An inquiry into prior British patents is totally inadequate for the purpose of establishing the novelty of the invention claimed. If we were the only country in which inventions are made and industries are developed this reference to prior British patents of the last 50 years would indeed be sufficient, but this is of course far from being the case. I admit that these prior British patents also comprise many inventions that have been made in other countries, but for all that they are far from forming an exhaustive record of what has been done before. The result is that the patent issued by the Patent Office may cover an invention, i.e., some new manufacture, or it may (and this is more frequently the case) merely cover an invention that is new with regard to prior British patents but not new with regard to the numerous discoveries made elsewhere. The law, however, as we have seen, grants a valid patent only for an invention that is entirely new.

This weakness in the administration of our Patent Law, which is due to the incomplete system of examination allotted to the Patent Office by the Act of 1902, is in my opinion by far the gravest inconvenience we have to contend with. Compared with the injurious effects of this failing of our patent system all its other deficiencies fade into insignificance. I am convinced in fact that it is this weakness chiefly which throughout the past has prevented our patent laws from exercising their full beneficial effect. The situation amounts to this, that the public can have no faith in the patent issued until the Law Courts have examined it with reference to all prior publications and have declared the patent to contain a new invention.

The consequences of this state of affairs are so notorious among people concerned with manufacture and in fact all industries that they hardly require much illustration. It may not as a rule be very difficult to invent some useful improvement; but, as every inventor knows, it is exceedingly difficult to get an invention introduced into manufacture. Years generally go by before a new invention is applied in the arts. Now if in addition to these difficulties the inventor has to overcome the general distrust of patents due to the fact that so many of them merely cover an old improvement, his task is little to be envied, and it is hardly to be surprised at if, after his fruitless efforts to introduce his invention, he becomes discouraged and allows his patent to lapse rather than pay the renewal fees required to keep it in force. On the side of manufacturers the situation is not much better. The industrial application of any invention generally entails considerable expenditure and is always associated with a certain amount of risk as regards cost of manufacture, the demand that may arise for the new article, etc.; if then in addition to such risk the manufacturer is not sure that the invention he is going to apply is protected by a sound patent, on which he can rely for protection during at any rate a limited space of time, his position is exceedingly difficult, and he can hardly be blamed for looking askance at inventions.

When in 1900 a Committee appointed by the Board of Trade and comprising Sir Edward Fry, Lord Alverstone, Lord Moulton, and other eminent lawyers, investigated the working of the Patents Acts, they readily recognised the serious objections that prevail against a system of granting patents indiscriminately, as was the case prior to the Act of 1902, and if their deliberations, which covered a good many subjects and seemed to favour an extensive system of examination, did not lead to a result of this kind, it may be presumed that this was due mainly to the fact that the question of a general system of examination was placed

outside the scope of enquiry the Committee was asked to make. The Committee stated in its Report (page 4): "Both from the evidence before us and from the knowledge possessed by members of our Committee, we are of opinion that the grant of invalid patents is a serious evil, inasmuch as it tends to the restraint of trade and to the embarrassment of honest traders and inventors, and this fact, coupled with the result of the foregoing enquiry, is in our opinion, a cogent argument in favour of same enquiry as to anticipation by prior Letters Patent."

All that was done at the time was the introduction of the Act of 1902, which established a system of examination covering the British patents of the last 50 years. I have attempted to show that unless the scope of this examination is enlarged very considerably, the result obtained will always be unsatisfactory and of little value to either the inventor or the manufacturer, and I submit as a first proposition in any programme of reconstruction, that the field of preliminary examination as to novelty should be extended to all prior publications, whether English or foreign, as this is the only means of ascertaining the novelty of the invention described in the specification.

Apart from the greater encouragement that would be given to industrial enterprise by the introduction of a general system of examination and the issue of more reliable patents, a very appreciable advantage would accrue by this system to scientific research. Whenever a research chemist, or an engineer engaged in design, would apply for a patent to cover an invention, he would, as soon as a search has been completed at the Patent Office, be informed of the several British, German, American or other patents that most closely approach his invention or appear to anticipate it. He would thus know at once how he stands, he would get the very information he wants, and if he finds that his invention is not new he would be able to strike out on a new line of investigation without further delay and without incurring the expense of acquiring patents in other countries.

There are many who will say that a comprehensive system of preliminary examination on the lines set forth is a task of such magnitude that it cannot be carried out. It will be remembered, however, that both Germany and the United States carry out a general system of examination, and that in a certain sense our Law Courts do so as well, for whenever the validity of a patent is questioned in litigation the courts take all prior publications into account when deciding whether the patent is valid or not. Surely if our judges, who, brilliant though they may be in judicial matters, are not as a rule familiar with technical questions, can determine whether an invention is new or old, our Patent Office with the help of a competent staff can be expected to do so. I admit that a scheme of this kind would require a greatly increased staff of competent examiners at the Patent Office and would entail considerable expenditure, but I suppose we can afford to spend some money on our Patent Office instead of making it a source of revenue, if the bulk of the nation is to benefit by an improved system of patent administration.

My contention is that the standard of a British patent should be at least equal to that of the United States patent, and that the scheme of examination proposed would not necessarily involve a more rigorous system of rejection than is applied in the States. I do not wish to advocate the German system of rejection according to which a patent is refused whenever the invention does not comply with a certain criterion of novelty. A considerably firmer attitude towards inventions that are obviously old would, however, be very

desirable, and in order to prevent hardship in all cases of rejection the applicant should have the right of appeal to a Board of Appeal comprising, say, the Comptroller-General or his delegate and three experts who are engaged in the industry to which the invention relates, each member of the Board to have one vote and the Comptroller to decide the issue when votes are equal. It would perhaps be advisable to allow a further appeal to the High Court if the applicant thinks that his case has not been fairly dealt with.

All the patents issued by the Patent Office would then carry with them the presumption of novelty as to what is claimed and there seems little doubt that their value as instruments of industrial enterprise would be infinitely greater than that of patents to which no such legal presumption can be attached.

In addition to the above general system of examination, some supplementary control of the issue of patents relating to chemical industry would seem necessary. It is well known that inventions relating to engineering, the mechanical arts, etc., can be illustrated and verified to a considerable extent by means of drawings and that no such illustration is possible as a rule in patents connected with chemical manufacture. Many inventors, and more particularly German manufacturers and chemists, have made use of this peculiarity of chemical patents in order to obtain protection for purely theoretical conceptions and speculations of a rather nebulous character. These patents are intended to obstruct and prevent subsequent inventors from receiving protection who have first conceived means of bringing such ideas to practical success. Many chemical patents moreover contain statements that are designedly misleading and sometimes the few data that contain the invention are drowned in a mass of more or less plausible statements that are intended to obscure the nature of the invention. Such patents might, of course, be attacked in court, but the expenses of legal proceedings connected with patents are much too high, and the period of opposing the grant of such a patent (two months) or of obtaining revocation (two years) has generally expired, when the patent is cited at the Patent Office as an anticipation of a new invention.

Anybody who has carried on research relating to chemical industry knows how heavily we are encumbered in this country with patents of this kind.

The new Act of 1907 has provided that samples of the products alleged to be obtained should be supplied, but these samples generally do not reveal much and are not submitted to any further examination and if the invention relates to an improved process of manufacture of a known product, samples are, of course, of no use whatever.

In order to establish some means of control it would seem advisable that in specific cases, in which the invention is highly problematical and the description is obviously quite inadequate, the Comptroller-General should have power to order a verification by experiment before granting the patent. If any statements are found that are obviously misleading or if it is found that in the hands of a skilled chemist the results claimed cannot be obtained, the Comptroller should be entitled to call for a fuller description, and should the applicant decline to give further particulars, the Comptroller should have power to refuse the grant of a patent, after allowing the applicant to offer explanations at a hearing. This rejection should be subject to an appeal to the Board of Appeal of the Patent Office. Possibly some measure of this kind might enable the Patent Office to prevent the delivery of obstructive patents. I do not, of course, mean to suggest that

all chemical inventions should be examined in this manner.

As an alternative to the experimental verification referred to, the system of granting patents in Switzerland deserves to be considered. In order to avoid patents with a vague description and claims covering more or less speculative data, the Swiss Patent Office has tied down the inventor to the description of one particular and clearly defined process and will not allow claims for a general method leading to the formation of various bodies. Section 6 of the new Swiss Patent Law is worded as follows: "Un brevet ne peut comprendre plusieurs inventions. En particulier les brevets ayant pour objet la fabrication de substances chimiques ne peuvent être délivrés que pour un seul procédé, qui, par la mise en œuvre de matières premières nettement déterminées, aboutit à une seule substance." This solution of the difficulty would appear to have considerable merit, but whether it works out well in practice I am not prepared to say. The obvious drawback of the Swiss scheme is that it is so easy for infringers to alter to some extent the particular process described and then claim to have made a new invention.

After having established our patents on a sound basis, i.e., that of the novelty of the invention, by means of the general system of examination proposed, we might think of making these patents permanently valid after allowing a period of several years, say five years, during which the public could obtain revocation of the patent on the grounds of anticipation, inadequate description, or prior use. During these five years the public would have an opportunity of adding any disseminated knowledge or information to the thorough investigation carried out by the Patent Office during the period of examination and the validity of the patent could then be looked upon as firmly established and no longer open to attack in court. The fact that it would be desirable for the Patent Office to establish the validity of British patents after a given number of years has already been advocated by Dr. E. F. Ehrhardt (see this Journal, 1916, 1249). It seems to me that this would indeed be quite feasible if a general system of preliminary examination on the lines I have proposed were adopted, but not otherwise. It stands to reason that a provision of this kind would greatly increase the stability of any new manufacture depending on patent rights and would enable the manufacturer to defend himself against infringers with greater confidence. It would, moreover, be impossible under these circumstances for some wealthy company to intimidate an inventor by telling him that his patent was not valid as the invention it disclosed was old, that they possessed prior patents and were entitled to make use of his invention without exposing themselves to an attack for infringement. No remedy for cases of this kind exists so far other than that of risking an action in court.

The above question of validity brings me to the second important proposition, which I venture to think ought to be included in a programme of reconstruction, and that is a revision of the procedure in court in cases of infringement.

It is well known that few actions in a court of justice prove as costly and uncertain in their issue as proceedings connected with patents. Many a manufacturer is deterred from taking up a new invention because he thinks that infringers are sure to turn up and that he will be unable to fight them. Others who have started some new line of manufacture based on patent rights prefer to put up with a certain amount of infringement rather than risk an action in court, their sales diminish and the royalties paid to the inventor fall in proportion, so that the latter does not get the full benefit of his invention.

All this detrimentally affects the interests of industrial development.

In chemical industry the situation is particularly bad. Any action brought against an infringer is dragged from court to court and the decision on the main issue, i.e. whether there is infringement or an improvement on the part of defendant, is often reversed over and over again.

Owing to the extraordinary condition of the law, a judge is expected to form an opinion on chemical questions that are often exceedingly intricate and would in some cases be puzzling even to a trained chemist. The judge, although very learned in the law, is unfamiliar as a rule even with the rudiments of chemistry and is therefore compelled to rely on the evidence of experts for guidance. But the very terms in which the experts speak may be almost as strange to him as the words of an unknown language, and make it an exceedingly arduous task for the judge to follow the dialogue between counsel and experts. We would hardly expect a chemist, no matter how distinguished he might be in his calling, to decide satisfactorily difficult questions of law. Yet we do expect lawyers who sit upon the bench as judges to pass an opinion upon equally difficult questions of chemistry. It is not surprising under these circumstances that the courts find it exceedingly embarrassing to do justice to all the highly technical evidence brought forward and that a tremendous amount of evidence has to be collected before a more or less satisfactory solution of the problem of infringement is arrived at.

In order to establish a more efficient and economical tribunal for the settlement of patent cases, it would seem preferable that no experts should be allowed to assist either plaintiff or defendant, but that they should sit on the bench with the judge and form a kind of "technical jury," that would be called upon to assist the judge in deciding the issue of infringement. This would greatly reduce the cost and duration of the action and a great deal of the uncertainty of patent litigation would disappear. A manufacturer or inventor whose patent rights have been infringed could bring his action in confidence and we should be spared the painful avowal of incompetence that can be found in so many decisions relating to patents.

By way of illustration of the manner in which actions for infringement relating to chemical industry are dealt with in court the following three cases may be cited, which have been selected after a perusal of the Law Reports and the Reports of Patent Cases of the last thirty years and may be taken as fairly typical.

One of the earlier actions for alleged infringement and at the same time one of the most notorious cases fought out in connection with the dye industry is the so-called "Blackley Red" case in which the Badische Anilin und Soda Fabrik brought an action against Levinstein Limited for infringement of their patent No. 786 of 1878 (R.P.C. 1885, p. 73—118). Sir Henry Roscoe, Dr. Caro, Dr. Peter Griess, Professors Dewar, Armstrong, and Odling, and other prominent chemists appeared in the action as expert witnesses. The patent referred to related to "Improvements in the production of colouring matters suitable for dyeing and printing" invented by Dr. Caro, and comprised the following results set forth in Claim (1): "The production of red and brown colouring matters which may be termed the sulpho acids of oxyazonaphthalene by the action of diazo compounds, which may be prepared from naphthylamine or from the sulpho acids of naphthylamine, upon any of the isomeric naphthols or of mixtures of the same, or upon any of the sulpho acids which may be prepared from either alpha-naphthol or beta-naphthol or from

mixtures of the same." Claim (2) referred to the use of dioxyazonaphthalene derivatives. The plaintiffs in their action claimed the usual relief (injunction, etc.) for an infringement of this patent and complained in particular of the sale by defendants of a colouring matter called "Fast Blackley Red." The defendants disputed the validity of the patent in view of prior publications in the "Berichte," etc., and they denied infringement. Professor Roscoe was asked by the judge to verify by experiment the first of the four methods described in the specification for obtaining the dyes in question, which consisted in combining diazotised naphthylamine with α - or β -naphthol and then sulphonating the product by heating with oleum. Professor Roscoe reported that the dyes claimed were obtainable according to this method. The process used by the defendant for obtaining Blackley Red, however, resembled the third method, which consisted in sulphonating naphthylamine, diazotising the product obtained and combining it with α - or β -naphthol. It turned out that this third method was the only one which led to the formation of a dyestuff of commercial value. The proceedings revealed that the defendant Levinstein used a process which differed in several respects from the third method described by Caro. Both parties started from naphthylamine but Caro sulphonated with 80% oleum, while the defendant used ordinary sulphuric acid; Caro used caustic alkali in the process of producing the oxyazonaphthalene, while the defendant used sodium carbonate; other differences in the process of manufacture were explained. The judge on rendering his decision defined the third process as follows (p. 84, lines 41—44): "The third process consists first of all in the manufacture of sulpho acids of naphthylamine, and after having got that those are mixed with beta-naphthol, and the sulphur therefore is to be found in the naphthylamine and not in the naphthol." Passing on to a comparison between the two processes under consideration the judge continued as follows: "There is no dispute whatever between the parties that, as regards the materials, Mr. Levinstein uses the same materials, that in his process in which he wants to obtain the sulpho acids of naphthylamine he does not use fuming sulphuric acid, but using what I consider to be a known equivalent to that, which he mixes with the naphthylamine, his process results in the production of naphthionic acid in the form of crystals; and I have no hesitation in saying that, so far as I am capable of judging, the process he has used is a process which is much cheaper and much simpler and results in giving you naphthionic acid in a much purer form, than it would do according to the process in the patent. It is said that this is an entirely new discovery of Mr. Levinstein's. I have said already and I repeat, although I am very diffident of expressing any opinion on a chemical matter, that, judging as well as I can from the information before me, I do not entertain a doubt that that naphthionic acid is produced by a chemical operation equivalent and known to be equivalent at the time the patent was taken out." Here the learned judge made a serious mistake, as oleum and ordinary sulphuric acid are far from being equivalent in their action on naphthylamine. While the former, particularly in the high state of concentration referred to (80%) and at a raised temperature, will, in addition to a certain proportion of monosulphonic acid, produce mainly various isomers of disulphonic and trisulphonic acids, which may or may not be valuable dyestuff components, ordinary sulphuric acid can be made to produce the single monosulphonic acid required, i.e., naphthionic acid, as was evidently the case according to Levinstein's process. The judge continued: "Having obtained this he then

proceeds to produce the diazo compounds. So far as I am capable of judging, I incline to the opinion that Clève's method was the only one that was known. In this case also Mr. Levinstein, by experiment, has found out a cheaper method, and I suppose a better method, than that of Clève for producing this diazo compound, and I will even assume for a moment in favour of Mr. Levinstein that he might be able, if a patent could be taken out for such a matter, to take out a patent for what he has done. But at the same time my own impression is this, that in what he has done he has simply, by experiment, and by pursuing courses well known in chemistry, adapted this particular naphthionic acid process to the processes which have been used for other subject matters, but for which it had not been found, possibly because they were not wanted, could be used with regard to naphthionic acid." (It is submitted that this argument would be fatal to a great many valuable chemical inventions.) "He has then got his diazo compound. Having got his diazo compound of naphthylamine and having got his beta-naphthol both in solid forms, he has to combine them. He does not use caustic soda, he uses another vehicle (sodium carbonate) and he says that there is a great difference in using that other vehicle from using the caustic alkali solution which is mentioned in the patent, and of the difference he says that whereas the caustic alkali solution spoils his colour, the vehicle that he uses keeps it perfectly good and in fact improves it, the result is that the diazo compound combines with the beta-naphthol and you then get the colouring matter you want."

The judge concluded that the two processes were the same, and decided the issue of infringement in favour of the plaintiffs. An injunction, prohibiting further manufacture, was granted against the defendant.

On appeal, the Court of Appeal reversed this decision, declaring Caro's patent to be invalid, because the specification did not differentiate between the useful and the useless processes described, all the processes being presented to the reader as of equal value, and the Appeal Court further declared that if the patent had been good, defendant's process would have been an improvement on plaintiff's process.

On appeal to the House of Lords, the latter reversed the decision of the Court of Appeal and restored the order of the High Court that "plaintiff's patent was valid and that defendant had infringed."

That the solution thus finally arrived at after several years of litigation is rather unsatisfactory will hardly be denied. After reading all the evidence disclosed in the proceedings (as far as it was made public) it would appear that the defendant's process closely approached Caro's invention, that the latter first pointed out the oxyazaphthalene derivatives referred to, that there was distinct merit in this, that Caro's specification was drawn up in good faith, that he probably did not wish to discriminate between the various isomers and final products obtainable as they were not sufficiently known at the time, that his patent should never have been demolished, that Levinstein's process should have been disclosed before a competent jury—as indeed the whole case—that both plaintiff's and defendant's processes should have been verified by experts and the dyestuffs obtained compared, that the question of infringement should then have been decided, and that, if Levinstein's process was found to be an improvement, the question of infringement should either have been waived or, if defendant's process depended on Caro's patent the defendant should have been ordered to obtain a licence to use that patent. A patentee cannot, in addition to the monopoly which is granted to

him, claim the right of being alone entitled to improve his process during the fourteen years of the life of his patent, as such a provision would have a retarding effect on inventive activity, which is contrary to the object of all patent legislation. Certain accounts tend to show that Mr. Levinstein's red dye was superior to any of the products placed on the market by plaintiffs, and that he successfully worked his process afterwards in Holland.

Another interesting action is that of Vidal Dyes Syndicate v. Read Holliday and Sons, Ltd., and Levinstein, Ltd. (R.P.C. 1911, p. 541—561, 1912, p. 245—284), which related to the manufacture of black sulphur dyes according to patent No. 16,449 of 1896 to H. R. Vidal. The patentee claimed the manufacture of black dyestuffs by "causing sulphur to react, either alone or in the presence of sodium sulphide, upon diamidophenols and dianidonaphthols or upon dinitrophenols and dinitronaphthols." The proceedings showed that the dyes produced by Vidal and those of defendants did not correspond, that according to the expert evidence of Professors Green and Morgan the directions in the specifications were insufficient to produce a black dye from dinitrophenol, and that under no conditions could a black dye be obtained from dinitronaphthol even applying all modern knowledge. Overruling this evidence, the judge decided that any chemist could find out by experiment the conditions necessary for obtaining black dyestuffs from each of the four substances referred to in the patent. The judge laid aside the principle, which is well established at law, that the specification should be sufficiently clear and precise to render further experiment unnecessary. The issue of infringement was decided in favour of the plaintiff. The defendants appealed and obtained redress from the Court of Appeal, which reversed the decision of the High Court and decided that Vidal's patent was bad because the processes claimed were not properly described and ascertained. The Appeal Court also held that defendants' dyestuffs were not produced by the process claimed and that there was no infringement.

In Nobel's Explosive Co., Ltd., v. Anderson (R.P.C. 1894, p. 115-129, 519-534, 1893, p. 164-169) the action related to A. Nobel's patent No. 1471 of 1888 for the manufacture of explosives having a horny or semi-horny character by mixing nitroglycerin with soluble nitrocellulose (i.e., dinitrocellulose). The defendant, Dr. W. Anderson, Director-General of Ordnance Factories, used insoluble nitrocellulose (i.e., trinitrocellulose). It was proved at the trial that, at the date of the patent, soluble (in ether-alcohol mixture) nitrocellulose and insoluble nitrocellulose were both well known and that each, as usually made, contained about 10% of the other. The processes described in the specification were equally applicable to both substances, and the results were horny or semi-horny explosives. The judge decided that as insoluble nitrocellulose was not mentioned in the claim this derivative was not within the scope of the invention described and that there was no infringement. On appeal the Court of Appeal confirmed this decision, and on appeal to the House of Lords the decision rendered in the first instance was likewise confirmed. It would appear that the question whether the use of insoluble nitrocellulose involved a distinct improvement, that could have been looked upon as a separate invention, should have been decided in the first place and that if no marked improvement could be established defendant's process should have been taken to be a colourable imitation. As the numerous experts arrayed on both sides could not agree, no decision was arrived at in this respect.

There is one further action to which I will

briefly refer, *i.e.*, *Crosfield and Sons v. Techno-Chemical Laboratories* (Brunner, Mond and Co. v. Lever Bros.) (R.P.C. 1913, p. 297), as in this case the judge himself points out the inconvenience of allowing experts to support the opposing parties. In this action Mr. Justice Neville refers in his decision about the well-known Normann patent for converting unsaturated aliphatic acids into saturated compounds, to the fabulous amount of time devoted to eliciting the opinions of expert witnesses upon the issues of the case, which the court alone should be left to decide, and says that "whereas the expert witnesses called for the plaintiff almost invariably take a strong view in his favour on each and all of the issues of the action, the expert witnesses for the defendant are equally confident the other way. It is rare to find any substantial difference of opinion between eminent experts upon matters of science whenever it is possible to dissociate the questions from immediate connection with the issues of the action."

I am aware that our courts sometimes summon an expert to assist and instruct the judge upon scientific issues, but this expert has no voice with regard to the real issue of the case, *i.e.*, whether there is infringement or not. This arrangement is certainly better than leaving the whole technical side of the case in the hands of the judge, but it entails serious objections. It may be easy to secure an honest expert, but it is difficult to find a truly impartial one. The more learned he is the more likely he is to have some previous knowledge of the very questions at issue and to have formed a previous opinion upon the matter at stake. No matter how conscientious he is, he is likely to approach the subject with a certain amount of bias, which may result in great injustice.

CONCLUSIONS.

The patents issued in our country contain no reliable evidence of novelty. Those that are granted for genuine inventions are inundated by a large proportion of worthless patents delivered for old inventions. A serious anomaly exists between the attitude of the Patent Office, which considers the fraction of industrial development only that is covered by the British Patents of the last 50 years, and the attitude of the courts, which in accordance with the law, consider all prior publications. A patent sealed by the Patent Office is liable to be upset in court on the grounds of anticipation as soon as it is issued. The inventor finds it exceedingly difficult to introduce his invention owing to the lack of consideration given to patents and the manufacturer is deterred from using a new invention because the patent he is offered may or may not be a valid instrument of defence against infringers.

It does not seem expedient to leave the novelty of the invention to be determined by the courts. The novelty of all inventions to be protected by patents should be investigated by the Patent Office by means of a general system of examination, covering all prior British and foreign publications. Without demanding any particular standard of novelty or applying the criterion of a "new practical effect" adopted in Germany, patents should be granted only for inventions that contain some novel feature over and above the inventions disclosed in the prior publications. All other applications for patents should be refused.

Specifications relating to chemical industry should, whenever the invention seems problematical or obscured by irrelevant or misleading statements, be verified by skilled chemists in suitable laboratories, so as to avoid the delivery of patents that are intended to obstruct. The supply of samples is deemed insufficient for this purpose.

The public should be allowed five years within which the patent could be revoked on the grounds

of anticipation, inadequate description or prior use, and the validity of the patent should then no longer be open to attack in court, so as to give greater security to any new manufacture depending on patent rights.

The courts find great difficulty in dealing with litigation relating to chemical industry and frequently fall into serious scientific error. The judge has to rely on expert evidence which he is unable to understand, because years of scientific training are required to be able to cope with the highly technical evidence brought forward. No demonstration *ad oculos* can, as a rule, be made. Great uncertainty, therefore, prevails with regard to patent litigation relating to chemical manufacture and even wealthy companies often prefer to put up with a certain amount of infringement rather than defend their rights. It is therefore proposed that all actions in court connected with infringement of patent rights should be tried in the presence of a "Technical jury," consisting of experts engaged in the industry or science to which the action relates, and assembled in the manner of a "Special jury."

DISCUSSION.

Mr. WALTER F. REID said that he considered there were a great many difficulties in the way of the inventor. The existing patent laws had, however, certain facilities for the inventor, and these should not be lost. With respect to the suggested jury of technical experts, he doubted its being a success owing to the difficulty which would be experienced in obtaining a panel who would view a patent in the same light as the inventor. He had known many inventions which had not been put to use because the technical experts did not believe in them, but which had proved to be useful inventions. He considered that our Patent Office fleeced inventors, deriving a profit from them of more than £100,000 a year, which was not to the advantage of the patentee or the public. It would be better for the country to spend the money paid for patents in the development of inventions. The 50 years' search had proved to be a complete farce; nobody wanted it and the practical results were worth nothing either to the investor or to the inventor. A complete search might be of more service. In the countries where a complete search was made the patentee obtained a patent which was as liable to be upset as the patents granted in this country. Inventors defeated their own ends by over-estimating the value of their inventions before they had actually been tested; no business man would spend money on an invention before it had been really tried. He considered the proposal to establish a laboratory for the testing of patents would not be a success and would be detrimental to the inventor. He thought the author was a little severe on expert witnesses when he said they were biased in favour of their clients. To put a limit on the period in which an invention was proved to be useful would be a disadvantage to the inventor, who ought to be secure in every way and ought not to have his patent turned down because someone did not agree with him. It was not generally known that on only 4% of the patents taken out were the fees paid up to the end of the term, and only 52% were kept going after the end of the fourth year. From the commercial point of view, therefore, it was quite clear that the fees charged were far too high, as it did not pay the patentees to continue their patents.

Mr. ARNOLD PHILIP said he would prefer a patent granted on the French system, under which the value of the patent was frankly left to be fought out in the courts; but for that a single fee should be charged, which should cover all payments, as was the case with American patents. A patent granted after a most thorough search by

the English Patent Office might be upset by information which had never formed the subject of a patent but had been published in some little-known book. The real value of a British patent, however careful a search might have been made, had to be decided by the courts, and therefore a search prior to granting a patent was of little real use. An author was very much better off than a patentee. The term of copyright covered a much greater number of years for a much smaller fee than a patent, whilst the patentee had to pay heavy renewal fees for short terms, always being liable to an action for infringement or declaration of invalidity.

Mr. J. W. GORDON said that if he understood Dr. Hay's suggestion, it was that an expert jury should be empanelled to assist the judge in the trial of an infringement action, whilst reference had been made to the expert body which assisted the Patent Office in Germany in deciding upon the merits of an application for the grant of a patent; these were two totally different things. His own view for many years had been that an expert jury to assist the judge at a trial would be an extremely useful innovation in our system of the administration of the patent law, but there were obvious difficulties in it, which he thought, however, could be successfully overcome. He believed that the author suggested taking the decision in the case out of the hands of the judge and placing the decision as to the attempt to infringe in the hands of the jury. That would not, in his (the speaker's) judgment, be an improvement at all. The expert jury should perform the same functions in these trials which the special or common jury, as the case might be, performed in the trial of an ordinary action at law. That, he thought, would be a useful innovation. It would secure the assistance of experts to the judge and that was a thing which it was extremely difficult to secure as matters stood, and in addition he thought it would tend to exercise a very valuable control over the evidence given by expert witnesses. The expert witness when called was entitled to answer questions that were put to him but he was not entitled to offer opinions of his own nor to introduce his own views except in so far as they were elicited from him by the questions put to him. Of course, neither party put questions which were calculated to produce an answer unfavourable to the party in question, and the consequence was that many points were not elicited at all which were of very great importance to a decision in the case, and through no fault of the expert witness but through the fault of the system, the opportunity was not given to the expert witness to disclose the whole of his knowledge bearing on the subject. The remedy for that in an ordinary case was, that over and above the questions which were put in the interests of the parties, the judge could, if he thought proper, put questions for himself in the interests of and to clear his own mind. The judge, if he were sufficiently familiar with the subject matter, might do that in the case of expert witnesses in, for instance, patent actions, but it happened very often that by reason of the technical character of the evidence given and of the very special nature of the subject matter under discussion, the judge did not feel sufficiently at home to take up the line of examination of expert witnesses on his own account and he rested satisfied with the examination and cross-examination, although it might by no means have cleared the matter satisfactorily to his own mind, for fear of making matters worse if he attempted to deal with it on his own responsibility. He thought that kind of difficulty would be almost completely eliminated in the trial of a patent action if there were an expert jury which could suggest to the judge the questions which were necessary to complete the evidence,

or even to put these questions for themselves. There was an obvious difficulty to which allusion had been made about providing the experts for a jury of this sort. The experts would probably be connected with the industry which was concerned in the action and they therefore would, in all probability, be more or less committed either to the one party or the other or to some view upon the subject. That, he agreed, was very largely true if the expert jury were confined to the particular craft with which the case was concerned. But in the case of a chemical question, for example, an expert jury might consist of engineers, metallurgists, and geologists. He did not suggest excluding the chemist by any means, but he thought it would be extremely unwise to exclude other experts and scientists. After all, what was wanted for the purpose of the investigation of such questions was the mind not of a person who knew already what was going to be said about it, but a person who could readily apprehend and pick up the evidence which actually was given. The question had to be decided and ought to be decided by the evidence adduced in the court of law, and therefore it was a disadvantage to have on the part of the body which adjudicated thereon, an opinion already formed. There was matter which was not brought forward in the evidence but which did bear upon the decision, and if the question of infringement were to be decided by something which had never been disclosed to either party they could not of course put their case fairly before the Court. The whole evidence upon which the case was to be decided ought to be laid before them in order that they might deal with it. If a decision were entrusted to experts who did not have to derive their information from the evidence, the persons who were responsible for putting the evidence before the Court did not have a fair chance of stating their case, because they were met in the mind of those constituting the Court with matters that had not been disclosed to them. It was of the very elements of the administration of justice that the decision of any case, whether scientific or otherwise, should depend exclusively upon the evidence which was adduced in the Court and submitted for the criticism and observations of the parties who were going to give the decision. It was the greatest mistake to suppose that one could proceed properly according to the German system of entrusting a decision to people who could follow the case independently of the evidence. The persons who were deciding should be people who had to take into consideration the evidence that was put before them, and it should be decided on that evidence alone. It was a very great advantage to have persons who had had a scientific training and who were accustomed to deal with scientific matters, but there was, so far as he could see, no object to be gained by choosing experts to decide the questions which had to be decided in a court of law, who would be able to decide them by the light of their own knowledge and independently of the matters which were brought forward in the actual discussion.

Dr. Hay had advocated a very extended search before the granting of a patent. He (Mr. Gordon) thought that he over-estimated its value. In Germany and America, where extended search was made, a very elaborate process was gone through before a patent could be granted, especially in Germany, and that was a real hardship to an applicant for a patent. At the time the applicant came forward, he was not in the fortunate position of a man who had a valuable property to uphold. He was in the position of an adventurer who was coming forward with something he hoped might prove to be a very great success, but up to this stage he had had nothing but trouble and expense in connection with it. If he were to be

exposed at the commencement to the same kind of opposition which he had under our system, five or ten years afterwards, when his patent had proved a success and he had put up a sum of money to deal with the contingency of litigation, he would be exposed to a very great hardship. He would be obliged to run the gauntlet of the German Office, but there was much more in the case of this country to be said than that. In that connection he drew attention to one very important and significant circumstance. We had some half dozen or more autonomous colonies with patent laws of their own, and these colonies always keep their eye on our legislation and what we did they usually did also. If there were to be established in this country an extended search through all kinds of literature, that extended search would be introduced in the legislation of all those colonies in two or three years' time, and then the unhappy patentee who wanted to take out a patent throughout the British Empire would have to submit to this search and expenditure over and over again, and he would have to fight half a dozen patent actions before he could get a patent for the British Empire. That seemed to be retrogressive. It was possible to suggest a unified British Imperial patent system. Thereby a patent, wherever it were granted, would be capable of being made effective throughout the British Empire without repeated examination and without a repetition of this elaborate machinery and costly expenditure. The innovations which were introduced in 1883 had had the effect of practically sub-dividing the British Empire into something like ten or a dozen different countries for the purpose of patent law. There had been a period in our history when we had made a very serious attempt to unify the British Empire for this purpose. That was in 1852 when under the generous impulse of the gathering brought together by the Great Exhibition of 1851 a system had been introduced by which patents could be taken out in this country and would have been regarded as valid in the dependencies. Unfortunately, that promise of an Imperial system had not ripened. The legislators of 1853 had not been so sympathetic as their predecessors, and they had introduced the system by which the colonies were placed on exactly the same footing as foreign countries for the purpose of reciprocal patent rights and had divided the British Empire up into a number of different countries for this purpose, with the result that at the present moment the cost of getting a patent throughout the whole Empire was prohibitive except for those with a long purse or an invention of proved value.

Mr. JACQUES ABADY said that necessarily chemical patents involving a great deal of investigation, a great deal of obscurity, and a great deal of uncertainty as to their future development offered greater scope for uncertainty in subsequent contests with rivals, and in proportion as a patent was simple, so was it less likely to be the subject of litigation. In regard to the question of the extended search suggested by Dr. Hay, he would apparently be satisfied with Section 7 of the Patent Act of 1907 if it were enlarged in its scope so as to take in specifications for patents which had been granted in foreign countries. He did not think that was likely to prove more conclusive than the present system, as it was not always prior specifications that were cited as objections to validity. Prior publications in various technical journals and various other matters were mentioned very frequently, and in proportion as an inventor leant upon an official examination, so he thought he would take less care in looking after himself, and would suffer a greater disappointment if in an action in

the Courts his anticipation of the stability of his patent proved to be false. After all, the Patent Office fees, covering what was a monopoly, if there were merit in the invention, for 14 years were only £100 or thereabouts, and it seemed to him that a patentee should take steps to see whether there was, in fact, anticipation before settling his final specification. A little more information from that standpoint would be worth 50-fold the most stringent public examination of anticipation. Dr. Hay appeared to be under the impression, and the discussion had proceeded as if it were a fact, that if a patent were tested in the courts, the novelty was guaranteed by the courts. That was not so; the court did not make any search as to novelty, but only dealt with anticipations referred to in the pleadings in the action. The discussion had proceeded as if in an action the question of infringement were the only issue. It might be so indirectly, but in nine cases out of ten the question of infringement was relegated to the background, and the point was, in fact, whether the invention was valid and the specification "sufficient."

In regard to the question of expert witnesses and infringement, he was sure that no counsel would ask an expert witness whether he considered one specification was an infringement of another. It was necessary to consider the state of the art and what was the invention that the inventor had made, at the time that he made it, and for such purpose experts were not wanted. Also, it seemed to him that if the functions of a jury were such as suggested, the jury would be deciding the action, and not the judge. Such a jury, as Mr. Gordon said, should consist of men who had the training and were capable of sifting the evidence placed before them. He failed to see what better training there could be than the training of the judges.

Dr. Hay had suggested that there should be a close time for patent actions, and that after a specification had been published five years an action should not be possible. But it was precisely in the first five years that the inventor did not want an action because he was then speculating money and getting together his commercial organisation. He believed that there was not one invention in 10,000 that came before the Patent Office that was worth bothering about, because it called for the use of no extensive amount of capital.

Mr. P. C. H. WEST considered that an extended search would result in delay in grant of patents and therefore an applicant would for a considerable time, possibly several years, be uncertain whether he would obtain a patent. In the United States and Germany, where the search was more extended, anticipations brought to light in this country were not infrequently overlooked. The search upon which decisions based upon the question of validity were come to were usually carried out by competent persons at the instance of patentee or manufacturer or other interested party. Amendment of the specification might in this country be effected at any time by applying for leave to amend and thus defects due to the official search might be removed.

In Germany there was no definite criterion of novelty; certainly it was required that an invention should produce a "new technical effect," but whether in a particular case an invention was deemed to possess this qualification depended largely upon the capacity of the patent agent. The extended search carried out in America resulted in the patentee presuming that his patent was unassailable, yet neither the number nor cost of patent actions had been reduced. It had been suggested that patents might be obtained for theoretical matter, but though broad claims might be obtained they did not cover theory only.

The suggestion of a laboratory for investigating the statements made by applicants was impracticable; it would involve heavy expenditure, and by whom would the expense be borne? He feared to contemplate the results of such establishment. Engineering inventions could not, as had been suggested, be verified from the drawings. With regard to the question of expert juries in chemical cases it had been suggested that the jury might consist of engineers. If engineers were to be left to decide the case, why not leave the matter to a judge, who certainly was accustomed to sift and weigh evidence? If in present conditions a case were properly fought, and the expert witnesses properly examined, the judge could decide the matter. In most patent actions justice was done.

Mr. G. E. PEARSON wondered how practical effect could be given to the various suggestions submitted for some modification, alteration, or adjustment of the Patents and Designs Act, 1907. That opened up a very large subject, and it seemed desirable to deal with it in a systematic manner from the point of view of the needs of chemical industry. He suggested that a competent committee should be formed of manufacturers engaged in chemical industry and who had practical experience of the taking out of patents and the working of them. Inventors associated with chemical industry who were not manufacturers should have an opportunity of joining this committee. The Act would be examined by this committee with the object of selecting those sections which in their working had proved unsatisfactory to the needs of chemical industry in this country. It would then be necessary to determine in what respect each of the selected sections had proved unsatisfactory and to suggest what modification, adjustment, etc., would be necessary to remedy the faults found. At this stage the committee would perhaps decide to co-opt the services of counsel experienced in the practice of patent law to advise upon the re-wording of the sections in order to give effect to the committee's recommendations and to safeguard any pitfalls resulting from such recommendations. If other industries largely interested in patent law reform, such as the engineering industry, tackled the subject on the same lines and the recommendations of the industries concerned were assembled and again reviewed by a fresh committee composed of the most expert men who had served on the industries committees, the considered opinion and recommendation of those industries chiefly affected ought to be arrived at. The opinions submitted that evening by various speakers would have the careful consideration of the Patent Law Committee of the industry with which he (the speaker) was associated, and no doubt there were many other members of the industry who would be only too pleased to appear before such a committee to render any assistance arising out of their own experience. In all recommendations made for modifications, adjustments, etc., of the Act, it would be necessary to consider the effect of reprisals from countries whose interests were unfavourably affected. Therefore the international arrangements would require careful attention.

In conclusion he mentioned a few items which might engage the attention of a committee formed on the lines suggested: (1) The attitude of Parliament in regard to any recommendation which appeared to aid the "inventor-manufacturer" in restricting the working of the monopoly granted him as opposed to the interests of the "inventor-non-manufacturer" who was naturally anxious to get his invention worked as widely as possible. (2) The alteration or repeal of Section 27, or alternatively the amalgamation of Sections 24 and 27 with suitable modifications,

to render it possible for Section 24 to achieve what had been expected from Section 27. (3) The revelation of a positive working formula for any protected substance. (4) Some means of revoking "blocking" patents after a short term.

Dr. F. B. DEHN said that no British patent had been declared valid by the courts. All the courts did was to declare it valid with respect to some particular point, but that would not prevent an attack from another point of view. The bearing of the objects of a patent on the public and the right of the public to redress must be carefully considered. He thought that as a rule British judges did not often go wrong and that justice was usually dealt out in this country.

Dr. HAY, in reply to the remarks made by Mr. J. W. Gordon, said he quite agreed that the jury of experts could be assembled on the lines of a common or a special jury, but although he admitted that experts who belonged to the profession to which the action related would be liable to form their opinion in advance and might disregard some of the evidence produced at the trial, yet it seemed to him that the more essential elements of the evidence would nevertheless be brought home to them by the pleadings and that a deficient appreciation of the minor points on the part of some of the experts would have to be allowed for in the hope that all the experts would not show a lack of attention to the same details, and that the main issue as well as all the more important subsidiary considerations would be properly dealt with. In any case, he hardly thought that experts who belonged to a different profession would be able to weigh up all the technical data of the evidence in a reliable manner. As an alternative to a technical jury, possibly two or three professional chemists, who had had practical experience in various branches of chemical manufacture, might be called upon to assist the judge in the capacity of assessors. These experts would have the advantage over a jury of being able to put questions themselves and at the same time the danger of having trade rivals sitting on the bench with the judge would be eliminated. With due deference to what had been said by other speakers, he did not think that the judge alone could be expected to do justice to the highly technical evidence brought forward in litigation relating to chemical industry.

Mr. Gordon's proposition that a British patent should be made to cover the whole Empire was a very valuable one. The adoption by the mother-country and all the colonies of a uniform system of patent legislation would, he thought, form a powerful stimulant to the development of the industrial resources of the Empire.

With regard to Mr. Abady's remarks, he was under a misapprehension if he thought he (Dr. Hay) meant to imply that the Courts carried out a search. The Courts did nothing of the kind, but they did take all prior publications into account that were submitted by the parties of the action, whether these publications were patent specifications or not, and whether they were in English, German, or other language, and in that respect the attitude of the Courts differed very considerably from that of the Patent Office, which granted a patent for anything that was not fully disclosed in the British patents of the last fifty years. He was not aware that he had suggested a time limit for patent actions. What he said was that the validity of a patent should not be questioned in court after a period of five years; that did not mean, of course, that a valid patent could not form the basis of an action for infringement throughout its duration.

Mr. Reid, Mr. West, and other speakers had admitted that the search carried out by the Patent Office was unsatisfactory, but they did

not favour a comprehensive examination by the Patent Office of all prior publications, which would of course include the journals. It was contended that such a search could be carried out privately before or after applying for a patent. In the criticism of the proposition of an extended search, the inconvenience or "hardship" to the inventor had, in his opinion, been over-estimated, and the advantage of having a patent that could be handed round with a certain amount of confidence, because it was known to contain something new and would therefore be treated with respect, had been perhaps under-estimated. There would no doubt be more trouble in obtaining a patent under the new system than hitherto, but it must be remembered that improvements of old inventions had to be differentiated from old inventions some day or other, if an invention were to be turned to account, and the sooner that was done the better. The prior patents and the journals were there in the archives of the Patent Office, and nothing was gained by ignoring them and putting off the day on which one would have to make sure whether the invention was new or old. If there were anticipations of the invention it was as well to know them at once, and the inconvenience that would arise, owing to a prolonged discussion with the Patent Office, would be small compared with the hardship experienced by an inventor who tried to introduce into manufacture a patent obtained under the present system of examination. Both from the point of view of the manufacturer and of the inventor the difficulties that presented themselves at this stage could only as a rule be overcome by having an extensive and costly search made with the help of an agent. Until such a search had been carried out the patent would always remain a very doubtful instrument of defence against infringers. As matters stood at present, nobody with any experience in patent matters would undertake to build up a new industry on the mere evidence of a British patent, as an undertaking of that kind would be little better than a gamble. The assertion finally that no absolute security would be gained by means of an extensive search could hardly, he thought, be considered an argument.

Manchester Section.

THE MANUFACTURE OF NITRIC ACID FROM NITRE CAKE.

BY DR. J. GROSSMANN.

(See this J. 1917, 1035.)

DISCUSSION.

In a written contribution to the discussion, Captain C. J. GOODWIN submitted that Dr. Grossmann's experiments would unfortunately, owing to existing conditions, be unlikely to lead to the working of the process on a practical scale. The process might be remunerative only while the war lasted, since the bulk of the sulphuric acid supplies, at present diverted for war purposes, would be released after the war, while at the same time a price corresponding to the value of the sulphuric acid would still have to be paid for nitre cake. Saltcake was not always saleable profitably, and it was not safe to rely upon a good market for it. It was known that practically the whole of the sulphuric acid charged into a nitric acid retort could be decomposed in the retort, forming slightly acid sodium sulphate, as described by Dr. Grossmann, but as the residue, being solid, was in an inconvenient form for removal, it was necessary

to restrict the reaction to the formation of a nitre cake sufficiently liquid for easy removal. The experiments showed that there was no advantage in the use of added carbonaceous matter, as decomposition of nitric fumes was less when no carbon was added. This was fortunate as such a mixture might easily lead to fires. A large-scale plant to work the process would, in addition to a suitable mechanically operated muffle furnace and grinding plant, require plant and towers of greater capacity than for the usual type of nitric acid plant in which only about 5% of the yield was recovered in the towers. A suitable form of muffle furnace would be that described in English Patent No. 4226 of 1915 (this Journal, 1916, 821), which is in operation for converting nitre cake and salt into hydrochloric acid and saltcake. For use in this furnace no difficulty was found in grinding the nitre cake sufficiently either by means of a disintegrator or under edge runners. Later it was found that, provided the salt was finely ground, it was not necessary to reduce the nitre cake below pea size. This would probably apply equally to the interaction of sodium nitrate and nitre cake, and he suggested that it should be tried. The saltcake obtained by Dr. Grossmann contained rather more free acid than was specified by users, but working continuously under conditions equivalent to those obtaining in a mechanical muffle-furnace in a properly designed plant, it should be possible to reduce the content to below 2%. As stated previously, he thought that no manufacturer would be prepared under present conditions to instal a plant to work this process, as it was not likely to be remunerative after the war, and there would be little opportunity, owing to the excess profits duty and similar financial measures, of making an adequate profit during the war. The rational utilisation of nitre cake lay, in his opinion, in the manufacture of hydrochloric acid of high strength such as would be obtained in a good mechanical furnace, and which would displace both nitre cake and sulphuric acid now being used for various non-essential manufactures. This process was in use prior to the war and would still be remunerative after the war, so that firms installing it would not be speculating unduly on the probable duration of the war.

Faraday Society.

PYROMETERS AND PYROMETRY.

Sir Richard Glazebrook presided at the first meeting of the Session of the Faraday Society, held at the House of the Royal Society of Arts on November 7th. The subject of the evening was "Pyrometers and pyrometry," and in opening the proceedings the Chairman referred to the great importance of the subject in industrial work, and alluded to the early days of high-temperature work at Teddington.

The following are abstracts of the papers read:—

PRODUCTION OF HIGH TEMPERATURE AND ITS MEASUREMENT.

BY E. F. NORTHROP.

Very high temperatures can be produced in the electric furnace when carbon or graphite is used as resistor, but the chemical activity of carbon at high temperatures renders it necessary to use a reducing atmosphere, and even then the products under treatment are subject to attack. Tungsten may be used as resistor at high temperatures, but a reducing atmosphere is necessary in this case also. Another disadvantage of the resistor type of furnace is its inherent thermal

inefficiency when used for fusing substances of high melting point. The author's conception of an ideal furnace is one in which the substance, contained in a cylindrical crucible, is able to absorb by induction alone a large proportion of the power supplied. The heat should make its appearance only in the walls of the crucible, or, better, in the substance itself. A 20-kw. furnace has been constructed on these lines, having in view the known limitations of the ordinary induction furnace. Heating is obtained by inducing, with comparatively high frequency currents in an inductor coil which surrounds the crucible, very large currents in the walls of the crucible or in its contents, if these are electrically conducting. The induction is obtained by electromagnetic induction without the use of any iron. The furnace differs radically from all other types of induction furnace by the entire absence of any interlinkage of a magnetic with an electric circuit. The necessary high frequency of the inducing current may be obtained in more ways than one. The simplest and most obvious method is to employ oscillatory currents obtained from the discharge of condensers. These oscillatory currents pass through an inductor coil of about fifty turns which surrounds the crucible, and is sufficiently separated from it to permit of both electrical and heat insulation. There is thus in effect a Tesla coil arrangement in which the voltage is transformed down and the current transformed up. It is to be noted that when a condenser of capacity C is charged to voltage V , energy is stored in the dielectric in potential form and in amount $\frac{1}{2}CV^2$. When the condenser is discharged this potential energy is released, and, becoming kinetic, may take the form of electric radiation as utilised in radio practice, or it may take the form of thermal energy or heat. When this principle is once recognised it becomes purely a question of design and engineering practice so to construct apparatus and select conditions that very little energy is spent in radiation and a large percentage of energy is converted into heat within a crucible and its contents—the necessity of the interlinkage of an iron magnetic circuit with an electric circuit being entirely obviated. Apparatus consisting of adjustable reactances, high tension transformers, and an entirely new type of discharge gap (which is nearly silent and operates without moving parts), two banks of condensers and a furnace inductor winding, constitutes a complete outfit for operation on a two-phase, 60-cycle, 220-volt supply circuit. The results so far obtained with this furnace are as follows:—1. It operates on a two-phase circuit, drawing an equal load from each phase. 2. It operates at full load with unity power factor for the supply circuit or with a slightly leading current. 3. It operates at any small fraction of full load without appreciable reduction in efficiency. 4. The metal-melting furnace will melt, starting at room temperature, about 45 lb. of brass in 35 minutes when watt-hour meters in the supply mains register a total power supplied of 18 kw. 5. The vacuum-type furnace will bring a crucible of Acheson graphite 14 cm. in diameter and 18 cm. high, filled with tin or glass, to a temperature of well over 1600° C. in 40 to 50 minutes, and a vacuum of not less than 1 cm. of mercury can be maintained during the process. Certain kinds of glass evolve a vapour under reduced pressure which diminishes the vacuum and makes the glass frothy. 6. Cylinders or crucibles of the above dimensions, or smaller, made of graphite, can be raised to a temperature of 1600° C. with an almost perfect uniformity in their temperature distribution. Cylinders of other materials, as of iron, nickel, or nichrome, may be raised in temperature until they start to melt. 7. The thermal efficiency, defined as the ratio of heat energy developed

within the crucible and its contents to kilowatt-hours supplied at switch terminals (both expressed in like units), may be made as high as 60% with the 20-kw. furnace described, and it is thought that a greater thermal efficiency may be obtained in a furnace of larger power capacity.

The furnace has been operated at 5400 and at 7200 volts at the condenser terminals. The frequency is the natural period of the oscillatory circuit of either phase. About equally good results have been obtained when working with 25,400 cycles and with 12,500 cycles per second. Protection from the high voltage is secured by surrounding the furnace casing with a grounded metal cage, and the crucible, in addition to being electrically insulated from the inductor coil with a cylinder of quartz glass, is likewise grounded.

It has been shown experimentally that by means of electromagnetic induction at high frequency, metal scrap, borings, turnings, etc., may be quickly raised to a melting temperature, then fused and superheated, even when contained in a refractory crucible of non-conducting material. Currents circulate in the subdivided mass, jumping with innumerable small arcs the contact resistances between particles. In this manner pure electrolytic iron, contained in a magnesia crucible, has been fused in a vacuum, carbon and presumably every other source of contamination being entirely absent.

This method of heating gives a type of furnace which it is impossible to destroy by burning out, as the only parts which get at all hot are the crucible, its contents, and the immediate layers of refractory lining. A layer of heat insulation of "silox" about 1 cm. thick surrounds the crucible, and this has been found quite sufficient to maintain the inductor coil below a red heat when the crucible and its contents are above 1400° C.

It is hoped that eventually, by using greater power input, it will be possible to melt metals belonging to the tungsten group in vacuum, and therefore make it possible to produce any kind of very high melting alloy free from carbon.

As regards the measurement of high temperature the author confined his remarks to the use of direct insertion pyrometers. The limits to accuracy set for high-temperature direct-insertion pyrometers are determined chiefly by the inevitable chemical modification of the pyrometric substance rather than by its fusion or destruction. With the best types of pyrometer-casing tubes at present obtainable, at a temperature in the neighbourhood of 1350° C. gases obtain access to the thermocouple wires, and contamination is produced. If the pyrometer is inserted in a reducing atmosphere, this contamination is particularly marked. Thus the author has never been able to use successfully, except for very intermittent service, a platinum-rhodium thermocouple in a reducing atmosphere much above the melting-point of nickel. A thermocouple of tungsten-molybdenum, though giving but a feeble e.m.f., can be used to measure extreme temperatures if it can be protected from access of hot gases.

Up to about 1300° C. the accurate measurement of temperature in any kind of atmosphere has been satisfactorily solved by properly constructed and protected platinum-rhodium thermocouples, the e.m.f. of which is determined by a potentiometer method. As a potentiometer is a somewhat delicate instrument, and as a direct deflection galvanometer, or millivoltmeter, must be intrinsically sensitive to measure the feeble e.m.f. of a platinum-rhodium couple, a robust portable instrument has been devised which operates on the potentiometer principle, but gives readings in millivolts or degrees by the deflection of a pointer. The accuracy and permanence of the instrument depend upon a permanent magnet

rather than upon a standard cell, in that the "current constant" of the instrument is all that affects the readings, the resistance being once fixed.

The author has also devised a direct-insertion pyrometer which reads high temperatures accurately. The instrument is constructed on the general lines of a very large mercury thermometer. The tin is contained in a "bulb" of close-grained graphite, and it expands, when the temperature exceeds about 700°C. , into the graphite "stem." The height at which the column of tin stands is determined by electrical contact. The scale is laid off or calibrated by noting the height of the column of tin at some two temperatures chosen within the range of a platinum-rhodium couple. The scale is extended above the higher temperature upon the assumption that the expansion continues linear to the highest temperature for which the combination, graphite and tin, is suitable. The upper obtainable limit of temperature to which it is practical to go has not been actually determined, but it is known that this limit is higher than 1680°C. , and it is thought to lie well above 1890°C. This pyrometer does not indicate, as a thermocouple does, a point-temperature, but registers the mean temperature over the space occupied by the pyrometer bulb. There does not appear to be any serious difficulty in preventing the graphite from oxidising and slowly wasting away. To prevent this it is proposed to inclose the bulb and a portion of the stem in a tube of a carborundum composition closed at the bottom. In the small clearance space between the bulb and the inside of this tube there may be inserted a filling of molten tin or a high melting glass. This jacket of molten tin or glass is expected to make a perfect shield against the attack of oxidising gases upon the graphite of the bulb.

In conclusion, the author emphasises the great possibilities of tin for extending the fundamental temperature scale above 1550°C. , the present limit of the gas thermometer. Only chemical contamination and temperature can affect either its resistance-change or its volume-expansion, and its chemical purity is easily controlled. Its resistance-increase and its expansion characteristics are, it is believed, as regular as is the increase in pressure of a gas of constant volume when its temperature is increased. Pure graphite, which makes an ideal container for tin, has an almost negligible expansion, and it is certain that both tin and graphite are undisturbed by a temperature elevation which goes far beyond that at which any gas can be used pyrometrically.

PYROMETER STANDARDISATION.

BY E. GRIFFITHS AND F. H. SCHOFIELD.

It is now generally agreed upon that the standard scale of temperature should be the thermodynamic. The corrections required to convert the scale of the constant volume nitrogen thermometer to the thermodynamic increase with temperature, amounting to about $+0.7^{\circ}$ at 1000°C. They are, in fact, almost within the limits of the possible error of experiment in gas-thermometer observations. Hence the problem of pyrometer standardisation resolves itself to an empirical calibration of the pyrometer, whether mercurial, thermo-electrical, or radiation, by comparison with a gas thermometer.

Comparison cannot be a direct one for each instrument requiring a temperature scale, so that the scale of the gas thermometer is preserved by means of auxiliary standards—the mercurial thermometer, thermo-element, or resistance thermometer, or by a series of freezing-points or boiling-points of pure substances.

The steps by which the scale of a pyrometer is obtained are generally as follows:—(1) The gas-thermometer worker compares his instrument with a thermo-element. (2) This calibrated thermo-element is then employed to determine the freezing-points of a number of pure metals. (3) A thermo-element is standardised by freezing-point determinations, assuming the values given by the gas-thermometer worker for these transition points. (4) The pyrometer and thermo-element are then compared under suitable conditions.

Gas thermometer work at high temperatures presents considerable difficulties, particularly in connection with design of furnaces for obtaining uniformity of temperature over the space occupied by the bulb. The National Physical Laboratory has adopted the following alternative methods for attaining a practical scale of temperature:—The hydrogen scale (0° to 100°C.); platinum resistance thermometer (-38.9° to 444.5°C.); the fixed-point scale, e.g., b.pt. of oxygen (-182.9°C.) and of carbon dioxide (-78.5°C.) to m.pt. or freezing point of gold (1063°C.) or copper (1083°C.); the uncertainty of the latter point probably does not exceed 2°C. Other fixed points have been determined, up to the melting point of platinum (1755°C.).

For thermo-electric pyrometers the working standards are calibrated by determining their e.m.f.s. at a number of well-established temperatures. The scale above 1000°C. at present depends on the freezing points of gold (1063°), copper (1083°), nickel (1452°), and palladium (1549°C.). Another point is suggested, viz., the freezing point of the eutectic of nickel and graphite, to which a value of 1330°C. is tentatively assigned. For the range 0° to 1600°C. there is no single expression which gives the relationship between temperature and e.m.f.; the simplest method is to construct a table which represents a smooth curve through the experimental points. Calibration by comparison with a standard thermo-element is simple and expeditious. Errors in thermo-electric pyrometry due to contamination, lag, and oxidation are considered, and apparatus for detecting contamination is described.

The resistance pyrometer, standardised in ice, steam, and sulphur vapour, gives a scale identical with that of the gas thermometer. This type of instrument is very free from liability to give false readings, and probably its greatest defect is the time lag.

The total radiation pyrometer is calibrated by means of electric furnaces, the pyrometer being focussed on a plug of refractory material and the temperature measured on a platinum-rhodium thermo-element. The range of standardisation is 500° — 1400°C. , whilst extrapolation gives points beyond this temperature. The total-radiation pyrometer is of very limited use with molten metals, owing to the haze or fog, and radiation from the walls of the crucible or furnace is likely to introduce serious errors.

Three types of optical pyrometer are in common use, viz., the disappearing filament type, the polarising type, and the wedge absorption type. Theoretically the polarising type is the best. The optical pyrometer is standardised by sighting on a "black body" furnace the temperature of which is determined by a thermo-couple. A tungsten-arc lamp is also suitable for calibration, e.g., over temperatures between 1350° and 2400°C.

BURYING THE COLD-JUNCTION OF A THERMO-COUPLE.

BY R. S. WHIPPLE.

The cold-junction of a thermo-couple in a research laboratory is usually immersed in melting

ice, but this is impracticable in the works, and the use of the "Thermos" flask has been resorted to: by this means it is possible to maintain the daily temperature within a range of 2°C . The author advocates the burying of the cold-junction; if this is done to a depth of 10 ft. beneath the floor of a fairly large building, the temperature will remain constant to within less than 2°C . throughout the year. There is no difficulty in burying the junction if Peake's compensating leads are used with Pt—PtRh couples. The method has been applied successfully to works practice.

AUTOMATIC CONTROL AND MEASUREMENT OF HIGH TEMPERATURE.

BY R. P. BROWN.

For temperatures up to 425°C ., and where the gauge is not more than 100 ft. from the instrument, it is preferable to use for industrial work a copper bulb filled with nitrogen and connected by capillary tubing to a helical expansive spring; the capacity of the bulb must be about fifty times that of the tubing. For higher temperatures the thermo-electric pyrometer has been almost universally adopted in the United States: for temperatures up to 1100°C ., a base-metal couple, one wire Ni 90, Cr 10%, the other Ni 98, Al 2%, is preferred, whilst for temperatures up to 1500°C . a platinum-rhodium thermo-couple is most satisfactory. For higher temperatures a radiation instrument is used. For measuring the voltage produced by the thermo-couple, millivoltmeters are available up to 1000 ohms or more; the weight of the moving element has been reduced to a minimum, e.g., to 526 mgrms., including pointer and spring, by the use of an enamelled aluminium alloy wire 0.003 in. in diameter. The pointer tubing is of aluminium with walls 0.002 in. thick. For greater precision of temperature measurement, the "Brown heat meter" has been devised; this consists of a high resistance millivoltmeter combined with a small dry cell and suitable rheostats to reduce the voltage of the cell from $1\frac{1}{2}$ volts to 0 to 60 millivolts. The thermo-couple is first balanced against the dry cell; the voltage of the latter is then determined by deflection, and the couple is then joined to the meter, so that by switching back and forth rapidly the voltage from couple or cell can be noted. A rheostat may then be used if necessary to bring the indication of the couple circuit to that of the cell circuit. To obviate errors due to sticking of the pointer, spring fatigue, etc., a standard cell with suitable resistors is supplied. The temperature of the instrument should be between 5° and 40°C .

An automatic control pyrometer is described in which the temperature in an electric furnace is measured by a Ni-Cr alloy thermo-couple which actuates a high resistance millivoltmeter. The pointer is depressed at regular intervals, and when the temperature rises or falls, makes contact with devices whereby the current is shut off or increased until the correct temperature is reached again. A similar device can be used to control the valves of a gas or oil furnace. An instrument has also been devised whereby it can be seen by coloured lights whether the temperature under observation is correct or not. It works on the same principle as the automatic control apparatus, except that the contact of the pointer with the contact pieces operates lamps of different colours according to whether the temperature is high, correct, or low.

In the discussion which followed these papers, Dr. W. Rosenhain suggested that the iron-carbon

eutectic might be used for a fixed point near 1130°C ., similarly to the nickel-carbon eutectic mentioned by Dr. Griffiths. Mr. S. N. Brayshaw said that he had found the eutectic Cu 60, Sn 40, very useful for standardising pyrometers for workmen.

PYROMETRY APPLIED TO THE HARDENING OF HIGH-SPEED STEEL.

BY J. O. ARNOLD.

High-speed steel is best hardened from a temperature of 1300°C . produced in a bath of barium chloride fused by the aid of iron electrodes. At Sheffield University simultaneous observations have been taken with five instruments: a Fery radiation pyrometer, a Fery spiral spring pyrometer, a Foster practical immersed pyrometer (containing a thermo-couple of nichrome and some other nickel alloy for a range from 500° to 1400°), the twisted end of the couple being immersed, a Leskole pyrometer (a modified Wanner), and a Mesuré-Neuel (a polarisation pyrometer). All these instruments are reliable only for temperatures above 900°C . Many discrepancies are due to want of skill of the observers. The mean of the bath observations was 1296°C ., a few extremes ranging from 1270° to 1310° . Another set of observations, with three instruments, gave the grand mean 1305° . When first using the 2-ton Siemens electric furnace in 1910, it was charged with $\frac{1}{2}$ ton of pig-melt of hematite iron, the metal cooled a little in the ladle for casting floor plates, and the casting temperature of the five consecutive plates taken, which yielded 1300° , 1280° , 1243° , 1258° , and 1208° : there was thus a fairly rapid fall (radiation loss) of temperature, the mean fall being 18° per plate. In 1914 Leskole and Mesuré instruments gave a suspiciously high casting temperature of 1525° . Later experiments yielded first-heat tapping temperatures of 1600° , 1550° , 1630° , 1670° , and 1620° , and in another series 1625° , 1600° , 1600° , 1600° , 1590° , and 1600° . Two solid points have been proved: the temperature inside the Siemens furnace is 1700° — 1750°C ., the tapping temperature of the molten metal 1575° — 1525°C .

THE DETERMINATION OF THE TEMPERATURE OF LIQUID STEEL UNDER INDUSTRIAL CONDITIONS.

BY C. JOHNS.

There is a marked thermal effect when liquid steel issuing from the tap hole of an acid open hearth is succeeded by the first flush of slag. Viewed through blue glass the slag is much brighter than the steel. The steel reflects the light of the sun or an arc lamp, while the slag is less efficient as a reflector; as good reflectors are poor radiators, the differences in emissivity have to be taken into consideration. The thermal effects can be studied with a Fery radiation pyrometer, but marked corrections must be made when different parts of the stream of metal are in the field. Optical pyrometers for monochromatic light have proved most useful, provided special precautions are observed. Liquid steel is best observed from a distance of about 12 ft. at nearly a constant angle, and to avoid fumes, from the clear side to the windward of the stream. Experienced observers can estimate temperature differences of 15° and even 10°C . merely by watching the steel through blue glass as it is poured into the ladle. Pyrometers should be able to give higher accuracy, and trained observers can indeed obtain readings agreeing within $\pm 2.5^{\circ}$ or at any rate $\pm 5^{\circ}$. For

each particular casting method of a class of steel it is only necessary to determine the "normal" temperature when the steel is tapped from the furnace; deviations from the normal by more than $\pm 10^\circ$ are avoidable in practice, at least for special steels.

In the furnace hearth there is a layer of, say, 4 in. of liquid slag between the flame and the liquid steel, 15 in. deep, and all the heat has to pass through this layer, which is therefore hotter. In correcting the apparent temperature readings, assumptions have to be made for the emissivities. The surface layer of slag consists of fused iron peroxide, which is assumed to have an emissivity of 0.50; the emissivity of the liquid steel is probably 0.40. Insertion of a patch of new silica brick in a seasoned wall may make a difference of 20°C . There is a temperature gradient in the liquid steel bath, which can be estimated by observing the stream, first of steel and then of slag, as it flows from the taphole into the launder. Nine consecutive determinations, taken at intervals of one minute, gave the following temperatures: clear steel, 1465° , 1470° , 1470° , 1475° , 1475° ; last steel, 1480° ; clear slag, 1495° , 1505° ; last slag, 1510°C . There is thus a rise of 15° in the first 5 minutes, and a sharper rise in 2 minutes as the slag appears. When the temperatures are determined at the top, middle, and bottom of a stream of steel and slag, the top of the steel is cooler than the bottom by about 15° , except when the metal is deoxidised in the ladle, in which case the top is hotter by 5° or 10° ; the bottom of the slag is always hotter than the top by about 5° . All these temperatures are remarkably concordant in many determinations, but uncorrected. Assuming an emissivity of 0.50 for the steel and making measurements with red light of $\lambda = 0.70 \mu$, the following apparent (and corrected) temperatures have been found: Centre of hearth, 1600° (1704°), centre of roof 1585° (1607°), tapping side wall 1625° (1732°), port block where gas last entered 1645° (1755°), exit port block 1635° (1745°), surface of bath before tapping 1625° (1754°). As regards thermal losses there is a sharp drop in the readings when the clean surface of the steel in the ladle is compared with the stream flowing from the tap hole; but once the steel has been covered by its protecting layer of slag, after five minutes, the thermal losses rapidly diminish.

TEMPERATURE DETERMINATIONS OF LIQUID STEEL.

BY W. MCCANCE.

In controlling the temperature in an open-hearth furnace the Siemens optical pyrometer is used, but it is difficult to keep the milliamperemeter constant, and this therefore requires frequent standardising. Testing a heated object by means of a thermo-couple and the optical pyrometer with different screens, the following differences were observed: thermo-couple, 1188°C ; Siemens optical, 1186° ; using three Wratten screens 750°C . In other recent tests of three new instruments, readings on the same opening (black-body conditions) have given in the three cases the values: correct, 15° low, and 20° low, the comparison standard being a thermo-couple. As regards the temperature inside an open hearth, the apparent temperature recorded by the optical pyrometer is the true temperature plus an amount which will depend upon the temperature of the flame, the uniformity of the furnace walls, and the reflective emissivity of the slag surface, all insufficiently known. As it is not advisable to shut off the furnace every time a determination is taken, it was decided that the best places to focus the instrument² on were the slag surface opposite the

port that the gas was entering and the furnace roof immediately above it. At first widely varying temperatures, 1500° to 1700°C . and over, were recorded. Towards the end of the operation, when the slag was thickening up, seems to be the time when there is the greatest tendency to put more heat into the furnace than the brick-work could stand. Ultimately it was found that the temperature could, by means of temperature observations, be kept between fairly close limits running from about 1630° to 1650°C . apparent temperature, with advantage to the life of the furnaces. When the metal is running out of the furnace, the observer should stand to the windward of the stream to avoid smoke; the diameter of the stream is also of influence, but that is generally within the limits of experimental error, as are also the differences in different parts of the stream. For practical purposes an accuracy of $\pm 5^\circ$ is all that is required. The presence of carbon, manganese, and chromium alters the apparent temperature of the steel, probably by altering the emissivity. An average apparent temperature of liquid steel is 1500° which, accepting Burgess' doubtful value for the emissivity of iron 0.40, gives a true temperature of about 1600°C ; casting temperatures below that figure are considered as cold heats. Although taking the furnace temperature seems to ensure that all casts will have the same degree of heat, other factors enter, of greater importance even than surface temperature. There is the amount of heat carried forward in the bottom of the hearth by the previous charge; the temperature of the bottom just before putting in the charge is no indication; as the surface is easily chilled by cold air from the door. The rate at which the charge has been melted, and the rate at which the bath boils also determine the heat put into the charge, and these problems have not yet been solved quantitatively. Flat surfaces of steel are always covered with slag or oxide which has a higher emissivity than the clean steel surface, and give too high readings; therefore the instrument should be focussed on a moving part of the stream of metal.

OPTICAL PYROMETRY IN NON-FERROUS METALS.

BY F. G. DONNAN.

When the radiation issuing from a hole is sighted, the conditions of "full radiation" (black-body radiation) are fulfilled, but when an open bath or stream of metal is observed, correction must be applied. In the case of molten copper and gold, the appearance of an open bath differs much more from full radiation than in the case of steel. The two metals have a strong selective reflection when cold not changing very much with temperature. The relation between selective emissivity and selective reflectivity is given by Kirchhoff's law: $E_1/E = A$, where E_1 is the emissivity of the substance, E the emissivity of a full radiator at the same temperature, and A the absorptivity—all for a particular wave-length λ . The quotient E_1/E , or absorptivity, may also be called "relative emissivity." If R is the reflectivity, then $E_1/E = A = 1 - R$. Plotting the E_1/E or A against λ (from 0.45μ to 0.7μ) and making temperature determinations by means of thermo-couples, a sharp discontinuity has been found in the emissivity at the melting points of copper, gold, and silver; liquid gold emits more in the red and yellow, and less in the blue, than solid, and the curves for the liquid and solid metals are quite different, but no temperature coefficient of relative emissivity has been discovered for the liquid metal over a range of 190°C . Similar relations hold for copper. Fused silver has a very low emissivity all through the range. The relation between

apparent temperature and true (black-body) temperature is not simple, and has to be referred to a definite wave-length λ ; the true temperature is that of a full radiator (black-body) emitting light of the same intensity as the substance. As the λ decreases from 0.784μ to 0.416μ , the black-body temperature of solid gold at its melting point rises from 891.5° to 1023.5° , and of the liquid gold from 931° to 1019° C. Similarly with copper; as the wave-length decreases from 0.7 to 0.5μ , the black-body temperature of the solid copper at its melting point rises from 896° to 1028° , and that of the liquid copper from 717° to 1026° C. The accepted thermo-couple melting-point of gold is 1063.2° , that of copper 1083.4° , and of silver 960.7° C. The experiments were conducted in reducing atmospheres; incipient crystallisation of the liquid and polishing difficulties of the solid are among the disturbing factors. The use of glasses, which are not monochromatic as assumed, probably accounts for the divergent observations of Burgess on copper. In using an optical pyrometer the light should always be observed at right angles to the surface, otherwise it will be polarised.

PYROMETRY FROM THE STANDPOINT OF FERROUS METALLURGY.

BY W. H. MATFIELD.

No ready and really reliable method for measuring temperatures at which steels are cast from the works standpoint is available. An optical pyrometer directed on to the slag, or on to the walls and roof of a furnace, will give indications of the temperatures of the areas sighted upon, but the author agrees with Burgess that there is no satisfactory relationship between the temperature of the furnace chamber and slag, and the metal lying in the hearth.

In experiments carried out with a number of heats, the optical pyrometer was sighted upon the steel running into the ladle, and in one instance the values obtained were about 1400° C. to 1410° C. A thermo-couple was also placed in position in the empty ladle prior to the steel being run in. As the steel gradually filled the ladle the temperature indicated by the thermo-couple increased until the couple was thoroughly immersed in the molten steel. The steel now was tapped from the ladle until the couple was quite free from the molten steel. A time-temperature curve was obtained in which a flat maximum range was observed, corresponding to the temperature of the steel whilst in the ladle. The values so obtained ranged from 1600° to 1625° C. With the thermo-couple method the freezing temperatures of steels have been industrially determined; with a 0.1% carbon steel the temperatures so obtained were 1480° to 1485° C., values in sufficient conformity with the present iron-carbon diagram.

For re-heating work platinum-platinum-rhodium thermo-couples in vitreous tubes are generally used at Sheffield University for temperatures up to 1100° C. The Cambridge optical pyrometer is also employed. This optical pyrometer gives results strictly comparable with thermo-couple readings when the steel body is in the furnace, but reads low when the object sighted upon is placed in the open air, owing to the black body conditions not being realised. If the conditions of the tests are kept consistent the readings from the optical instrument, whilst they must be checked by transposition to absolute temperatures, yield a ready means of checking temperature in such works operations. If considerable care is exercised the temperature of a mass of steel in the furnace will be recorded as 60° to 100° higher than the temperature of the same mass of steel when taken outside the furnace.

Determination of the temperatures of steel bodies undergoing forging and rolling operations presents another interesting problem. In forging, particularly, the hot body has a large area in intimate contact with the large masses of steel forming the hammer and die, and as the body is rotated during the forging operation the outside becomes considerably cooled.

Whilst the thermo-electric pyrometer forms an accurate, convenient, and easily adjustable instrument for use in annealing operations, sufficient attention is not always given to the manner in which the couple is placed relative to the steel. Either an optical pyrometer intelligently used or a properly standardised platinum-platinum-rhodium thermo-couple is adequate. Silver-constantan and nickel and nickel-chrome couples may safely be employed in low temperature work.

The following results for thermal conductivity have been obtained by supplying a known amount of heat at the centre of a bar 1 cm. in diameter, the ends being kept at a constant low temperature, and the temperature gradient measured. The fall of temperature along the bar was measured by copper-eureka thermo-couples. These results are at room temperature over a range of 10° C. to 40° C., and the electrical conductivities are given for comparison.

Material.	Relative thermal conductivity.	Relative electrical conductivity.
Wrought iron	100.0	100.0
0.9 % carbon steel, as rolled ..	65.3	58.4
25 % nickel steel	25.6	12.25
Air-hardening nickel-chrome steel, as rolled	40.6	34.5
High-speed steel, as rolled ..	38.0	36.2
High-speed steel, hardened ..	28.8	17.2

It has been suggested that the ratio between the two conductivities should be constant at a given temperature, and increase in proportion to the absolute temperature. Experiments by Jaeger and Dieselsdorff show that the relation is only very approximately satisfied in a comparison of different metals. The above figures emphasise this and indicate only rough agreement among different kinds and conditions of steel.

A NEW TYPE OF THERMO-COUPLE.

BY F. ROGERS.

The author described a thermo-couple the ends of which have refractory material moulded around them and in firm contact with the end of the sheath. The wire-ends are not united to a hot junction, but were placed in contact with the molten metal. A steady reading is instantly obtained, and the pyrometer can be withdrawn before the stem is damaged by the heat. The tip is alone heated to the temperature to be measured; possibly the wires melt or alloy with metal over a length of $\frac{1}{16}$ in., but the electric circuit remains continuous. The air enters the sheath near the head and blows out through holes a little above the end; the cold-junction trouble is avoided by placing the cold-junction inside the sheath near the air-blast inlet. The following temperatures have been calculated from the resistance ratios: solidification of cobalt-chrome high-speed steel in crucible, 1530° C.; solidification of copper in open furnace, 1062° ; temperature in a 70-ton open-hearth steel furnace during melting down, 1450° C. In these trials the end of the pyrometer was actually immersed in the metal, for $3\frac{1}{2}$ minutes in the last case, in which the stem was 9 ft. long, air-cooled, and clad with heavy clay sleeves.

Immersion of the pyrometer tip for from 2 to 10 seconds is sufficient and a layer can be ground off the tip if contamination is suspected.

THE MEASUREMENT OF HIGH TEMPERATURES BY MEANS OF POTTERY MATERIALS.

BY H. WATKIN.

The discovery that the contraction of pottery materials which takes place during the firing could be conveniently measured was made by Josiah Wedgwood in 1772. The Wedgwood pyrometer, based on the principle of the contraction of clay under the influence of heat, was then probably the best instrument in existence for the measurement of high temperatures. Its usefulness, however, was limited to the degree of heat needed to bring about the maximum contraction of the clay or body used for the test-pieces; nevertheless, as this temperature was much higher than the English potters then required, it was negligible from the potter's point of view. In recent years it has been considerably improved, first, in the materials of which the test-pieces are made; second, in the form and method by which they are made; and third, in the instruments by which the test-pieces are measured.

An improvement has been effected by the adoption of a round disc made under pressure from steel tools, with a hole through the centre for the purpose of being readily withdrawn by an iron rod during intervals of firing, and made of materials which contract progressively and regularly through a much wider range of temperature. The steel gauge used for these pieces is made in such a manner as to measure accurately to $\frac{1}{100}$ in., and also shows the percentage contraction of the piece corresponding to this.

Buller's trial-rings are also based on the principle of the contraction of clay. This system, which has been adopted by all the leading potters throughout Great Britain, consists of a specially made clay ring, measuring $2\frac{1}{2}$ in. in diameter. As the ring contracts during the different stages of firing, the changes as shown on the gauge are noted on special charts provided for the purpose, and a practical guide and check upon the firing is thereby obtained.

In 1826 Voight and Light perceived the advantage of observing the fusibility of pottery materials. They made a series of mixtures of china clay, felspar, and lime, etc., with different softening-points, made up into cones, which distorted in such a manner as to be easily observed when they reached certain temperatures. In 1886 Seger made a series of cones having melting-points from 1150° to 1390° , which he numbered 1 to 35; these were subsequently increased by Cramer, who produced a series with lower melting-points from 590° to 1130° , and which were numbered 022 to 01. These cones were introduced to the English potters about 1892, and about 1898 they were made in England for the first time by Messrs. Holderoft and Co., who made the mixtures up into bars instead of cones, which, suitably suspended in a refractory cage, are more easily read or observed by the sagging which takes place during firing, unlike the Seger cones, which sometimes lean in the direction of vision, and consequently the distortion is concealed.

A still further use was made of this principle by the introduction of heat recorders and discoverers by the author in 1899. The recorder is simply a block of very refractory ware, with five circular recesses sunk into its top face. In these recesses are placed little pellets of fusible materials of definite composition and melting-point. The fusion-point of each mixture has been determined by comparison with a standard electrical pyrometer. While specially designed

for simply recording temperatures attained in parts of ovens, etc., inaccessible to observation, the recorders may also be used with advantage as pyrometers. They have proved very useful as such to many industries, including pottery and porcelain manufacture, brick-tile making, gasworks, glassworks, annealing furnaces, smelting furnaces, rolling mills, enamellers, etc. By the use of these the firing-points of the pottery and porcelain manufacture, both at home and abroad, were obtained, and are given in a table which was published in 1902.

All the colours, golds, lustres, etc., usually fired in enamel kilns, are fired at temperatures below 910° C. Many of these are fired up at 690° to 730° , and if taken to about 800° are faulty or completely spoiled. A coral red colour which was good at No. 3 to 4 recorder= 670° to 690° , was faulty at No. 5= 710° C., and completely spoiled at No. 6= 730° C.; the bright gold usually called liquid gold was not fastened on the glaze by the fire at No. 2= 650° , was good at No. 3= 670° , hard at No. 4= 690° , and spoiled at No. 5= 710° , etc. Hard glaze kilns for tiles are usually fired up at below No. 19= 1020° C., and glost ovens below No. 23= 1100° C. The effects of temperature on the colour given to a glaze by certain metallic oxides show how important it is that these points should be known with accuracy. Thus, an orange-red glaze produced by uranium oxide at 950° C. is turned to a brown at 1050° C.; a purple glaze produced by manganese at 950° C. is turned to a brown at 1050° C.; a red-brown glaze produced from chromium at 950° C. is turned into a green at 1050° C.; a turquoise glaze produced from copper at 950° C. is turned into a green at 1050° C.; a yellow glaze from chromium at 950° C. is turned into a green at 1050° C.; a black glaze produced from iridium at 950° C. is turned into a grey at 1050° C.

All these forms of pyrometer based on the principle of the softening-points of ceramic mixtures are very extensively used for industrial operations where high temperatures are necessary. They have, however, a serious limitation, since they do not register the length of time at which the temperature remains at any particular point during the firing.

BASE-METAL THERMO-ELECTRIC PYROMETERS.

BY C. R. DARLING.

Base-metal couples possess distinct advantages, one of which is the development of an e.m.f. several times as great as that given by a Le Chatelier couple of platinum and platinum-rhodium alloy, which enables more robust indicators and recorders to be used, or a more exact reading to be taken over a given range. Another is that the pyrometer itself may be strongly constructed. Although inferior to the Le Chatelier couple with respect to the temperature range over which they may be used—the upper limit being 1000° C. for continuous use—base-metal couples still enable temperatures to be measured which comprise many industrial processes, such as hardening, tempering, and annealing, and have proved satisfactory in practice for such purposes.

The couples commonly employed are iron-constantan; two iron-nickel alloys of different composition; and two different nickel-chrome alloys, known as Hoskins' alloys. In some cases iron alloys containing aluminium are also used, the couples chosen being such as to yield a relatively high e.m.f., increasing uniformly with temperature. Some of these alloys tend to change on heating continuously, in such a manner as to alter the e.m.f. of the couple. This danger may be reduced to a minimum by the careful selection of the alloys used, and due care in their manufacture. Pro-

longed heating near the limiting temperature appears to affect all alloys, even those of platinum and rhodium, and thermo-electric stability can only be ensured when the common working temperature is well below the limit to which the couple may be used for an occasional reading.

Up to the present, no base-metal couple has been brought into use capable of being used continuously at temperatures above 1000°C. ; and it has consequently been necessary to use a Le Chatelier couple, or a different type of pyrometer, for higher ranges of temperature. The author suggests a means of extending the range over which base-metal couples may be used, by utilising the e.m.f. developed by a junction in which one or both of the metals may be in the liquid state. As shown below, the boiling-points of many common metals are sufficiently high to indicate that a temperature of at least 1500°C. might easily be read by the aid of liquid couples:—Al 1800° , Ag 1955° , Sn 2270° , Cu 2310° , Ni 2330° , Fe 2450°C. Investigation indicates that in general the thermo-electric properties are unaffected by fusion, and that a temperature-e.m.f. curve shows no discontinuity at the fusion point. Exceptions to this rule are furnished by bismuth and antimony, both of which show an abrupt bend in the curve at the melting-point. Generally speaking, however, change of state from solid to liquid does not affect the thermo-electric properties, and it would therefore appear possible to measure temperatures by the aid of fused couples, and that all that is necessary to apply the method in practice is to produce a working pyrometer on these lines.

To test the feasibility of such a pyrometer, a graphite block was made with two holes drilled into its upper surface so as to contain the ends of two silica tubes, down which slack-fitting rods of the metals forming the couple were passed so as to make contact with the graphite block. When one of the elements was known not to fuse at the temperature employed, it was threaded at the end and screwed into the graphite to make a sure contact. The arrangement was inserted in the tube of an electric furnace; and on fusion of one or both of the elements the circuit was maintained, the liquid portion in the furnace being continuous with the solid part outside. The ends of the metals were connected to a millivoltmeter by wires of the same material, and readings of e.m.f. taken at various temperatures measured either by a calibrated thermal couple or a radiation pyrometer sighted on the lower end of the graphite block; the latter serves to prevent the mixing of the fused metals, and the e.m.f. developed is the same as if the metals were actually in contact. At present results up to 1000°C. only are available, this being the limiting temperature of the furnace used, but the regularity of the increase in e.m.f. with temperature with a number of couples would appear to justify the assumption that the method might be used up to 1500°C. , or even higher. This arrangement has proved satisfactory for experimental work, and no great difficulties are anticipated in designing a workshop pyrometer on these lines.

REMEDIAL CAUSES OF UNRELIABILITY ENCOUNTERED IN THERMO-ELECTRIC PYROMETRY, ESPECIALLY IN SYSTEMS OF THE BASE-METAL TYPE.

BY G. E. M. STONE.

A reliability within 10°C. can often be obtained

in base metal thermo-couples; but when more than one instrument is in use, combined with various recording instruments, readings fairly correct at first, may fluctuate by 50° after a few hours. The non-homogeneity of the materials is a first serious obstacle to the working of such couples. Iron-constantan couples which are much in use, fail owing to particular changes at the critical points, and when the furnace temperature is not uniform or the rates of heating and cooling are varied, the readings fluctuate. It is the same with nickel. Owing to this want of homogeneity the "cold-junction error" is quite an uncertain quantity as well, and that cannot be cured by compensating leads.

In fire-rods, in which one element of the couple surrounds the other in the form of a tube, two faults are often noticed at an early stage. The central wire is electrically welded to the tip of the tube; the two materials have different expansion-coefficients, and the friction between the insulating sheaths of fireclay or porcelain and the wire is often sufficient to force the tips out from the weld. Secondly, the central wire is frequently overheated during the welding and turns spongy and mechanically weak. A cure can be effected by adopting small beads of fireclay for the insulation. A common fault of all couples (not only of base-metal) is that the ohmic resistance of the two parts is not rigorously the same. The principal source of error is that the terminal resistance of the measuring instrument is made too small. In such a case an imperfect contact, a little dirt getting between the contacts at the heads of the fire-rods, or between the prongs of an electric switch, an addition to the length of the leads by a few inches, wires getting locally hot by radiation from the furnace or by lying on the ground, may set up appreciable errors. When the total resistance of the pyrometer is about equal to that of the recording instrument, an increase of the connection resistance by 0.12 ohm may lower the reading by 15°C. Warping wooden bases for instruments and their leaning against masses of iron, which cause magnetic leakage, are other remediable causes of trouble; vertical needles with depressors bearing against pads, which vary in moisture, are also objectionable; hollows develop in the depressor and catch the needles, and the central holes of circular charts are not accurately punched. Again in concentric connection for the heads of fire-rods the central connection and its insulation are not always sufficiently secured.

The author exhibited a pyrometer of the stem pattern, the tube consisting of two parts; the lower portion is a silica tube closed below; the upper portion an open brass tube, the junction being effected by means of slots and set screws for adjusting the design. The rod inside the tube is also two-part; the lower portion consists of fused silica, the upper of an iron rod; the silica rod is cemented into the junction piece, which is slotted to allow for expansion; the iron emerges through the cap of the tube and is joined above to a lever. The silica rod rests on a mass of metal or alloy (the charge) placed in the bottom of the silica tube, the metal being the same as that which is to be melted in a crucible. The stem is inserted into the crucible, and when the metal there fuses, the charge in the stem also fuses and the rod in the stem sinks, forcing the lever up. To prevent the silica rod from being caught by the solidifying charge, the lever is pressed by a spring catch into a recess and held there; the charge thus solidifies level and the instrument is ready for re-use. A sheath is pushed over the lower end of the stem to prevent contamination of the silica tube with clay.

Obituary.

GEORGE THOMAS HOLLOWAY.

The death of G. T. Holloway on October 24th deprives this Society of a member who had been for many years closely connected with its activities in several directions. He served on the Publication Committee since 1907, attending the meetings regularly until ill-health prevented this. He was also Chairman of the London Section from 1912 to 1913.

Born in Battersea on October 19, 1863, he received his early training at the Royal School of Mines. In 1884 he became Junior Assistant in Chemistry under Sir Edward Frankland and later under Professor (now Sir Edward) Thorpe. Two years later he commenced practice as a consulting metallurgist and assayer, in Chancery Lane, London, and in 1889 opened testing works at Limehouse for the examination of chemical and metallurgical processes and for treating ores on a small commercial scale. In 1910 he removed his laboratories and office to Limehouse, where additional premises were taken for necessary extensions.

From 1889 to 1897 he was an Assistant Examiner to the Board of Education and from 1912 to 1914 Examiner in Metallurgy to Birmingham University. In 1908-9 he served as Juror on the Metallurgical Sections of the Franco-British and Imperial International Exhibitions.

In 1915 Holloway was appointed Chairman of the Royal Ontario Nickel Commission, and to this work he devoted practically the whole

of his time during the last two years. This commission was appointed to enquire into and report upon the resources, industries, and capacities in connection with nickel and its ores in the province of Ontario. The Report of the Commission, issued during the present year, is a volume of over 800 pages, and testifies to the immense amount of work carried out by the Commission. It is generally acknowledged to the most valuable and complete monograph on the subject that has ever been printed (see this Journal, 1917, 490.)

In addition to his connection with this Society, already mentioned, Holloway was a member of the Councils of several other Societies, including the Institute of Chemistry, Institution of Mining and Metallurgy, Society of Public Analysts, and Chemical, Metallurgical, and Mining Society of South Africa. He was a very active worker on many Committees of these Societies, and also served on the Imperial Institute Advisory and similar Committees which were the outcome of the special conditions arising out of the War.

He made numerous contributions to technical literature, among which mention may be made of the paper before this Society on the Relations between the Chemical and Metallurgical Industries (this Journal, 1910, 53), which clearly shows his earnest desire for a closer co-operation between chemistry and metallurgy.

He assisted Sir Beverton Redwood in the preparation of the first edition of "Petroleum," and contributed several articles to the first and second editions of Thorpe's "Dictionary of Applied Chemistry."

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou 8. Paris (3e.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Hazardous chemicals [acids]; Packing and plant handling of.—N. A. Laury. National Safety Council, New York. Met. and Chem. Eng., 1917, 17, 407—408.

THE best method of safe and economical packing of one or two hundred pounds of corrosive liquid for transport is in wood-packed glass carboys. It is dangerous to empty carboys by means of compressed air as they are apt to burst. Breakage of carboys is often caused by partial crystallisation of the contents, for example, concentrated sulphuric acid or glacial acetic acid. Stoppers of carboys are often secured by coating with plaster of Paris and fastening down with cloth, but the shaking in transport causes splashing and the acid very soon attacks the plaster and causes it to crumble. The safest practical stopper is a glass or earthenware plate held in position by a wire clip. The plate is made to fit by grinding or using a rubber or asbestos washer. If this form of stopper is used care must be taken to leave an air space in the carboy, usually about 10%, to allow for increase of pressure due to variations of temperature. The greatest danger in handling carboys in wooden boxes arises from the sudden falling away of the bottom or sides of the box, owing to corrosion of the nails or weakening of the wood by acid, but this can be prevented by treating the wood with a preservative.—J. H. P.

Contact catalysis; Theory of.—W. D. Bancroft. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 16 pages.

A REVIEW of various facts and theories of catalytic action has led the author to regard the adsorption of one or more of the reacting substances by the catalyst as the determining factor controlling catalytic action, so that a solid catalytic agent may be considered as equivalent to a solvent and may therefore displace the position of equilibrium in the system. The general cognate conclusions are also drawn, that only substances which are adsorbed by a solid are catalysed by it, but that the catalytic influence of a solid may not in all cases result wholly from the increased surface concentration. As a result of selective adsorption, different catalysts may give rise to different reaction products and a catalytic agent will tend to produce the system which it adsorbs the more strongly.

—D. F. T.

Catalytic agents; Poisoning of.—W. D. Bancroft. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 26 pages.

THE various cases of the poisoning of catalysts are discussed, e.g., in the Deacon process for chlorine, the Haber ammonia process, the Sabatier process for hydrogenating oils, and the effect of platinum on the decomposition of hydrogen peroxide and on other reactions. The question of the adsorption of gases by the catalyst is considered

and it is pointed out that, as contact catalysis involves adsorption (see preceding abstract), a decrease in this adsorption, due to the presence of a film of solid, liquid, or gas on the catalyst, will cause a reduction in the reaction velocity; the action of "poisons" on catalysts is believed to be exerted in this manner by the occurrence of such an adsorption process which interferes with the normal adsorption of the reagents; this normal adsorption may also be affected by the reaction-products, the presence of which may, therefore, also cause a decrease in the reaction velocity, as indeed is the case in the combination of carbon monoxide or sulphur dioxide with oxygen in the presence of platinum. The influence of mercuric cyanide and other "poisons" on the catalysis of the decomposition of hydrogen peroxide by platinum is due to selective adsorption of the "poison" by the platinum; the action of mercuric cyanide in decreasing the electrolytic oxidation of sodium thiosulphate at a platinum anode is probably due, at least in part, to reduction of the adsorption of the thiosulphate by the anode. The effect of fluoride ions, chloride ions, etc., in increasing the over-voltage at a platinum anode is attributed to a diminution of the activity of the metal of the anode in accelerating the conversion of atomic oxygen into the molecular condition.—D. F. T.

The sub-station problem of electrochemical plant. Yardley. See XI.

PATENTS.

Fractional distillation of liquids, washing of gases by liquids, and cooling of gases and liquids [; Filling material for apparatus for —]. G. E. Darier, Chêne, Switzerland. Eng. Pat. 104,163, Dec. 14, 1916. (Appl. No. 17,994 of 1916.) Under Int. Conv., Jan. 29, 1916.

CLOSELY wound coils of wire, rod, or thread of metal, glass, or other suitable material are used as a filling for apparatus for the fractional distillation of liquids, washing of gases with liquids, etc. The drops of liquid which collect on the coils extend by capillarity between adjacent convolutions and wet their outer and inner surfaces so as to form in the case of each coil a cylinder with continuous liquid walls.—J. H. P.

Packing or filling for absorption, recovery, or scrubbing towers or the like. W. Oates, Leeds, and E. B. Robinson, Newcastle-on-Tyne. Eng. Pat. 109,915, Jan. 23, 1917. (Appl. No. 1107 of 1917.)

HOLLOW packing pieces are so constructed that the bulk of the absorbing or scrubbing liquid passes through lateral slots in the pieces in one row into the interiors of the pieces of the row next below. The accompanying figure illustrates a section of such filling material, the slots being shown at *a'*. The lower ends of each section are open; the upper ends may be open or closed.—W. H. C.

Desiccating liquors containing matter in solution or suspension (milk and the like); Means for —. H. C. Booth, London, J. L. Baker, Maidenhead, and Solva Ltd., London. Eng. Pat. 109,471, Sept. 11, 1916. (Appl. No. 12,829 of 1916.)

THE liquid is sprayed downwards into a drying

chamber by a jet operated by compressed air, and fixed centrally in a supply pipe for heated air. The hot air and atomised liquid enter a bag filter within the drying chamber. The air and moisture pass away through the bag, and the solid particles are caught by the fabric and fall into a receptacle at the bottom, when the bag is periodically shaken. The liquid enters the jet by a central pipe which is surrounded by the compressed air pipe. The two pipes are so connected together by means of a stuffing-box, that although the central pipe is left free to expand, the relative positions of the nozzles are not affected. By adjusting the compressed air nozzle vertically with respect to the liquid nozzle, the fineness of the spray, and hence the size of granules produced, may be controlled.

—W. H. C.

Elevating or lifting apparatus for acids or the like. T. Bradbear, Birmingham. Eng. Pat. 109,522, Oct. 30, 1916. (Appl. No. 15,425 of 1916.)

THE liquid enters the vessel, 1, through the non-return valve, 5, and fills the space outside the float, 3. The float rises, opens the air escape

valve, 21, and closes the compressed air inlet valve, 20. When the space outside the float is filled, the liquid overflows into the float so that it sinks and reverses the valves. Compressed air then enters and forces the liquid through the pipes, 7, 8, into the rising main through the non-return valve, 27. The pipe, 7, dips relatively lower into the acid in the float than the pipe, 8, does into the acid in the surrounding space, so that some liquid is always left in the outer space. When the float is empty it rises and reverses the valves, so that the operation begins again.—W. H. C.

Drying and aerating machines. J. A. Sparks, C. E. and W. M. Clark, Elk City, Kans., U.S.A. Eng. Pat. 109,595, Aug. 8, 1916. (Appl. No. 8780 of 1917.)

THE shaft of the machine described in Eng. Pat. 108,520 of 1916 (this J., 1917, 996), is provided with a thrust collar supported on co-acting bearing rings, having ball bearings or other anti-friction devices between them and contained in a casing.

—W. H. C.

Drying materials in sacks or the like; Apparatus for —. H. P. Dinesen, Herlev, Denmark. Eng. Pat. 109,965, July 30, 1917. (Appl. No. 10,934 of 1917.) Addition to Eng. Pat. 100,697 (this J., 1916, 915).

A SACK containing the material to be dried, e.g., corn or seeds, is supported in a frame over an air shaft. Hot air may be either drawn through the sack into the shaft or blown from the shaft through the sack. The grating on which the sack rests may be arranged to hold sacks of any size.

—J. H. P.

Treating and cooling air and gas; Apparatus for —. Heenan and Froude, Ltd., and L. Cruyt, Manchester. Eng. Pat. 109,648, Sept. 19, 1916. (Appl. No. 13,260 of 1906.)

THE air is passed through a casing in which annular rotating deflectors are either partly immersed in liquid or sprayed with liquid. The deflectors consist of a number of curved blades so formed that the liquid is spread as a film over the blades and is not atomised. Cooling drums, as described in Eng. Pat. 11,183 of 1911, may be arranged alternately with the deflectors, and the outlet of the casing is provided with an annular rotary eliminator against the blades of which the air strikes and deposits its moisture.—W. H. C.

Heating water or other liquids; Apparatus for —. H. Hocking, Liverpool. Eng. Pat. 109,926, Feb. 12, 1917. (Appl. No. 2069 of 1917.)

THE apparatus comprises two sets of U-tubes, one on each side of a vertical partition in a casing and fastened to a tube plate. Low-pressure steam is passed through the casing and the liquid to be heated through the tubes.—W. H. C.

Drying, mixing, and grinding apparatus. G. Calvert, London. Eng. Pat. 109,838, Sept. 26, 1916. (Appl. No. 13,643 of 1916.)

IN apparatus similar to a ball mill, the grinding chamber, which may be of stoneware, is made independent of, and is clamped to, the rotating frame which carries the hollow trunnion and rotating gear. The grinding chamber has an opening which registers with the hollow trunnion, and the latter has an extension provided with a brush for clearing the passage.—W. H. C.

Grinding or crushing pan mills. J. Twaddle, Coatbridge. Eng. Pat. 109,855, Oct. 9, 1916. (Appl. No. 14,306 of 1916.)

A PAN mill in which the pan rotates about a central axis whilst the rolls revolve upon a horizontal shaft, is provided with a scraper resting on the bottom and held in position by two pins which are fixed to a bracket and project downwards into two corresponding holes in the scraper. The bracket is preferably attached to an upper cross rail or angle iron in such a manner that the position of the scraper can be adjusted.—W. H. C.

Compressors for ice making or refrigerating machines. K. Lightfoot, and The Lightfoot Refrigeration Co., Ltd., London. Eng. Pat. 109,851, Apr. 2, 1917. (Appl. No. 14,032 of 1916.)

THE compressor is directly coupled to the engine and is operated at a high speed, the valves being operated positively by springs and tappets.

—W. H. C.

Impregnating liquids with carbonic acid or other gases; Apparatus for —. A. A. Pindstoffe, Copenhagen, Denmark. Eng. Pat. 109,958, June 21, 1917. (Appl. No. 8950 of 1917.)

THE impregnating chamber has a sliding valve connected to the liquid-supply pipe and actuated by a regulating device placed in the impregnated liquid in the lower part of the apparatus. A

number of pipes lead from this valve to compartments from which the incoming liquid flows down in thin films along wires, chains, gauze or the like, and meets an ascending stream of carbon dioxide. The impregnated liquid is collected in the lower part of the chamber.—J. H. P.

Impellers or fans; Earthenware —. Kestner Evaporator and Engineering Co., Ltd., J. A. Reavell, and W. G. Mann, London. Eng. Pat. 110,025, Oct. 5, 1916. (Appl. No. 14,171 of 1916.)

THE boss of the impeller is provided with a central conical opening which fits upon a corresponding conical portion on the shaft, the taper in both cases being of the order No. 5 Morse. The shaft is fitted with a collar, and the impeller is fixed to the shaft by means of a metal bearing-plate at the front of the boss and draw bolts connecting the plate and the collar and passing through slots in the boss. The free end of the shaft may be provided with a tongue which enters a slot in the bearing plate.—J. H. P.

Mixing-machine. G. A. Welzenbach, Peoria, Ill. U.S. Pat. 1,240,274, Sept. 18, 1917. Date of appl., Apr. 18, 1917.

A TILTING mixing hopper provided with an agitator is mounted on a frame, which also carries two shafts. One of the shafts is driven by external gear and the second shaft is driven from the first by gear operated by a clutch. By means of clutch gear one shaft drives the agitator and the other the tilting mechanism, each being operated independently.—W. H. C.

[Gas] filtering apparatus. G. S. Brooks and L. G. Duncan, Depue, Ill., Assignors to New Jersey Zinc Co., New York. U.S. Pat. 1,240,305, Sept. 18, 1917. Date of appl., Nov. 1, 1916.

A BAG, connected with a flue through which the dust-laden gas to be filtered is supplied to the bag, is provided with external mechanical means, operating at several points, for shaking the bag by causing it alternately to collapse and expand, to detach the collected particles.—W. H. C.

Leaching apparatus. L. C. Trent, Los Angeles, Cal. U.S. Pat. 1,240,904, Sept. 25, 1917. Date of appl., Aug. 24, 1914.

A RECEIVING vessel is provided with a filter bed at the bottom covering a vacuum chamber which is connected to the suction of a pump, and the liquid withdrawn is returned under pressure through a rotary agitator in the vessel. Liquid may also be forced by the pump in the reverse direction through the filter bed. A discharge outlet is also provided in the receiving vessel for the withdrawal of settled tailings.—W. F. F.

Separation of liquids from solids; Process of and apparatus for the continuous —. H. C. Behr, New York. U.S. Pat. 1,241,905, Oct. 2, 1917. Date of appl., Aug. 13, 1914. Renewed Mar. 26, 1917.

COMPRESSED air is supplied by a fan through a hollow shaft to air chambers within a pulley having a perforated rim with annular flanges. A travelling foraminous belt wider than the pulley passes round it, and mixed liquid and solid is fed between the pulley rim and the band so that it is carried round in a thin layer. The liquid and solid are separated by the combined action of the compressed air and centrifugal force.

—W. F. F.

Gas filtering apparatus. New Jersey Zinc Co., New York, Assignees of G. S. Brooks and L. G. Duncan, De Pue, Ill., U.S.A. Eng. Pat. 109,742, Mar. 9, 1917. (Appl. No. 3516 of 1917.) Under Int. Conv., Nov. 1, 1916.

SEE U.S. Pat. 1,240,305 of 1917; preceding.

Grinding-mill. E. F. McCool, Assignor to The McCool Mfg. and Trading Co., Victor, Colo. U.S. Pat. 1,241,749, Oct. 2, 1917. Date of appl., Dec. 16, 1913.

SEE Eng. Pat. 19,982 of 1911; this J., 1915, 1077.

Method of sealing glass bulbs [containing a gas in solution]. U.S. Pat. 1,241,229. See XVIII.

Digesters [for boiling materials under pressure]. Eng. Pat. 110,015. See XVIII.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Vertical [gas] retorts; Experiments on steaming in continuously operated —. J. E. Blundell. Manchester District Inst. Gas Eng., Oct. 27, 1917. Gas J., 1917, 140, 213—217. (See also this J., 1917, 860.)

THE experiments were carried out at an installation of Glover-West vertical retorts at Macclesfield, of a normal capacity of one million cubic feet of coal gas per 24 hours. The productive capacity has been increased 20% by passing steam into the charge in the retort, the yield of tar and ammonia being also improved. The plant was already provided with means for admitting a moderate amount of steam to the coke chambers during the discharging operations, and by modifying the conditions water-gas could be made *in situ*, thus obviating the inconvenience of a separate "blue" water-gas plant, with its attendant fluctuations in quality of gas produced, etc. The heating arrangements were altered by a readjustment of the waste gas and secondary-air dampers, and the settings were worked with a minimum amount of chimney draught. The rate of travel of the products of combustion through the chambers was retarded. The temperature in the lower combustion chambers was raised to between 1300° and 1400° C., and in order that the body of coke should be sufficiently heated for the water-gas reaction, the speed of extraction of the coke was reduced by about 10%. Chimney dampers and waste-gas dampers had to be cleaned regularly or the heat dropped sufficiently to increase the CO₂ content of the gas. The temperature of the gas in the off-take pipe was 200° C., in the gas-collecting main 95° C., and at the outlet of the retort-house governor 70° C. The pressure of steam varied with the different classes of coal, a hard, dense coke requiring a greater pressure of steam than a more open and friable one. Steam from Lancashire boilers at 100 lb. pressure was supplied by passing it first through a reducing valve and then through a nozzle of 1-inch bore. The following results are given, for the ordinary method and for the new method with steaming. Cub. ft. gas per ton at N.T.P., 12,049 and 15,358 respectively. Gross calorific value, 530 and 509 B.Th.U. per cub. ft. Total incombustibles, 10.7 and 10.9%. Coke made per ton of coal, 13.6 and 13.36 cwt. Analysis of gas collected over 24 hrs. gave the following results: CO₂, 2.9; C₂H₆, 2.2; O₂, 0.2; CO, 13.9; CH₄, 22.8; H₂, 53.23; N₂, 4.77%. Calorific value of coke, 12,700 B.Th.U. per lb. Liquor (10-oz.) made 25.3 galls. and 32.68 galls., tar 10.9 galls. and 16.61 galls. under the old and new conditions respectively. The tar under the new conditions was of better quality, showing an increase in benzol, toluol, naphtha, creosote, etc., and a decrease in pitch. Steaming does not appear to have exercised a very deleterious effect on the material of the retort. No doubt more fuel is consumed when producing water-gas, an approximate estimate being an addition of 1 lb. of coke per 100 lb. of coal carbonised. The loss in coke for sale per ton of coal is made up as follows:—

Carbon converted into water-gas in the retort, 25 lb.; extra fuel supply to the producer to effect the water-gas reaction, 25 lb.; fuel supply to boilers to generate steam, 24 lb.; total, 74 lb. The saving effected by steaming on an annual output of 200 million cu. ft. is given as 30% in cost of coal, and in weight of coal as 3577 tons.

—J. E. C.

Combustion; Fractional —. W. D. Bancroft. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 10 pages.

THE present knowledge of the relative rates of combustion of various gases, especially in the presence of catalysts, is reviewed, reference being made to the work of Henry, Hempel, Bone, Landolt, and Calvert. The following are some of the conclusions drawn. At low temperatures the nature of the catalyst may determine which of two combustible gases will burn more rapidly; in the presence of platinum, hydrogen burns more readily than methane or ethylene; in the presence of copper oxide at 250° C. all the free hydrogen, in a mixture of this gas and methane, can be burned without the decomposition of any of the methane; in the presence of fireclay ["chamotte"] at 500° C. hydrogen burns more readily than methane; in borosilicate glass bulbs at 300°—400° C., methane, ethane, ethylene, and acetylene undergo oxidation much more rapidly than hydrogen or carbon monoxide. The relative rates of combustion of hydrogen and carbon monoxide depend on the conditions, and in a mixture of methane and oxygen with hydrogen or carbon monoxide exploded by an electric spark, the methane burns more rapidly than either hydrogen or carbon monoxide. By suitable selection of the catalyst with a mixture of methane, hydrogen, and oxygen, it should be possible to obtain all intermediate stages from complete combustion of methane to that of hydrogen, and it appears probable that in the absence of solid catalysts and at high temperatures methane burns more readily than hydrogen. At very high temperatures, also, the specific effect of the solid catalytic agent will become negligible.—D. F. T.

Oils and tars; Studies in the production of — from bituminous materials. J. C. Ingram. School of Mines and Met., Univ. of Missouri. Bull. No. 4, Vol. 3, May, 1917.

FOUR cannel coals (from Missouri and Illinois) and two bituminous coals were distilled in a horizontal gas-fired retort under similar conditions, the charge in each case weighing from 25 to 35 lb. The gas produced was measured and collected after passing successively through two condensers, and three gas-washers containing water. Tables are given showing the amounts of gas and oil (or tar) obtained, and the temperature of the retort, at half-hourly intervals during the tests. The oils obtained from the cannel coals were fractionated to yield gasoline (up to 150° C.), kerosene (150°—300° C.), and lubricating oil (above 300° C.), and coke. The bituminous coals yielded small quantities of tar (5.35 to 12.5 gall. per ton) composed of paraffins, olefines, aromatic substances, and a large proportion of bitumens. The cannel coals gave comparatively large amounts (28.1 to 69.7 gall. per ton) of oils, composed chiefly of liquid and solid hydrocarbons of the methane and olefine series, together with cresols and asphaltic bodies. The cannel oils averaged about 11% gasoline (similar to that produced commercially by the cracking process), 40% kerosene, and 40% lubricating oil containing 25% of solid paraffins. Maximum gasoline production was obtained by distilling between 450° and 550° C. Hard paraffin and kerosene were formed in largest quantity between 550° and 650° C., while above 650° C. soft paraffins, heavy oils, kerosene, and bitumens

were the main products. A yield of between 3500 and 8100 cub. ft. per ton of very rich gas was obtained from the canal coals, the time of maximum production being between the fifth and sixth half-hours. Only one sample gave a saleable coke.—T. St.

Action of coal gas on plants. III. Action of coal gas, whilst passing through soil or water, on roots and leafy branches. Wehmer. See XVI.

PATENTS.

Solid fuel. R. Bowen, Cheltenham. Eng. Pat. 109,995, Sept. 30, 1916. (Appl. No. 13,914 of 1916.)

IN the manufacture of an artificial fuel, the mixed materials are submitted to pressure between successive additions of the mixture, and are heated to form stratified blocks, the face of each layer being treated to prevent perfect adhesion; *e.g.*, it may be cooled by treatment with compressed air, a fine spray of water, or a suitable powder, or the successive layers may be separated by layers of hydrated lime, fine coke dust, etc.—J. E. C.

Fuel; Process for manufacturing —. J. Miller, Seattle, Assignor to N. and H. Krantz, King County, Wash. U.S. Pat. 1,241,648, Oct. 2, 1917. Date of appl., Apr. 18, 1916.

COMBUSTIBLE refuse is dried and ground into particles of substantially uniform size, and is then heated and mixed with crude oil (20 parts), pitch (20 parts), and a mixture of rosin, charcoal, and gasoline (10 parts to 50 parts of the refuse). The product is moulded into blocks.—W. F. F.

Gas generators; Device for preventing escape of gas from —. W. J. Mellersh-Jackson, London. From C. M. Stein et Cie., Paris. Eng. Pat. 109,933, Mar. 14, 1917. (Appl. No. 3716 of 1917.)

A MOVABLE member, adapted to be placed around or adjacent to a slice hole, is fitted with a nozzle and a flexible tube for supplying gaseous fluid under pressure, or a stream of gaseous fluid may be directed across the mouth of the slice hole to form a screen and to prevent escape of gas.—J. E. C.

Liquid fuels for firing furnaces and for high compression oil engines. G. E. Heyl, London. Eng. Pat. 110,023, Oct. 5, 1916. (Appl. No. 14,148 of 1916.)

MINERAL oil is treated with solid caustic alkali to neutralise any acids and to form compounds with any sulphur present. The oil is cooled to eliminate naphthalene, and then heated to promote the solution of pitch, which is added to the extent of up to 50%.—J. E. C.

Hydrocarbons; Combining liquid — to render them suitable as fuel when used in internal combustion engines. J. A. Stoneham, London. Eng. Pat. 110,132, July 10, 1917. (Appl. No. 9954 of 1917.)

PETROLEUM derivatives having a flash point above 120° F. (48° C.) and coal tar distillates having a flash point between 80° and 90° F. (27°–32° C.) are mixed, generally in equal quantities, and to the mixture is added about 25% of benzine, with or without 0.5% of ether.—J. E. C.

Hydrocarbons; Process of and apparatus for producing light —. J. E. Holmes, Cushing, Okla. U.S. Pat. 1,241,979, Oct. 2, 1917. Date of appl., Aug. 31, 1915.

MEASURED quantities of petroleum oil or distillate and natural gas are heated to a high temperature

in a retort which communicates with an expansion chamber, means being provided for maintaining a predetermined pressure in the retort, and for permitting the mixture to flow to the expansion chamber when this pressure is exceeded. A high pressure is developed by vaporisation of the oil, and the mixture is then caused to expand under adiabatic conditions, whereby the heavier constituents are condensed, thus permitting the separation of the lighter constituents by subsequent condensation.—T. St.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Electrode; Arc light —. K. Tornberg, Lynn, Mass., Assignor to General Electric Co. U.S. Pat. 1,240,628, Sep. 18, 1917. Date of appl., Mar. 13, 1916.

ARC lamp electrodes are made by filling a conducting tube with a powdered mixture of barium peroxide and titanium carbide, and heating the top of the filled tube until oxygen is liberated from the peroxide to enter into exothermic reaction with the carbide. The action is propagated throughout the whole length of the tube, and the mass is then allowed to cool.—B. N.

Tungsten lamp; Incandescent —. E. Friedrich, Berlin, Assignor to General Electric Co., New York. U.S. Pat. 1,240,700, Sep. 18, 1917. Date of appl., June 11, 1913.

A SEALED lamp bulb is provided with a tungsten filament, and a solid inorganic compound containing oxygen, such as barium chlorate, which is placed in a position so as to be heated by the filament. The compound, at the temperature attained by the lamp, has an oxygen-dissociation pressure not greater than that of a first-class vacuum, thus maintaining an oxygen atmosphere at this pressure during the life of the lamp. The oxygen reacts with the vaporised tungsten to form solid and substantially transparent, non-volatile reaction products, which do not increase the pressure in the bulb.—B. N.

Distillation of materials containing cellulose; Process for the dry —. H. Von Hochstetter, Assignor to Holzverkohlungs-Ind. A.-G., Constance, Germany. U.S. Pat. 1,241,789, Oct. 2, 1917. Date of appl., Apr. 2, 1913.

SEE Fr. Pat. 455,345 of 1913; this J., 1913, 937.

III.—TAR AND TAR PRODUCTS.

Studies in the production of oils and tars from bituminous materials. Ingram. See IIA.

PATENT.

Naphthalene from [coal-tar] hydrocarbons; Process for removing —. G. E. Heyl, London. Eng. Pat. 109,836, Sept. 25, 1916. (Appl. No. 13,589 of 1916.)

AFTER the usual treatment of hydrocarbon liquids with dilute alkali, the bulk of the naphthalene is separated by cooling, and a quantity of concentrated or solid caustic alkali sufficient to neutralise the residual tar acids is added before or during distillation. When the alkali is added before distillation, the naphthalene separates on cooling or standing; when it is added during distillation the naphthalene separates in the condenser.—F. W. A.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Tetrazisazo dyestuffs; Blue—. Akt.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 101,967, Oct. 5, 1916. (Appl. No. 14,170 of 1916.) Under Int. Conv., Oct. 22, 1915. Addition to Eng. Pat. 14,789 of 1915 (this J., 1916, 171).

1 MOL. of a diazotised naphthylaminesulphonic acid, other than 2-naphthylamine-4,8-disulphonic acid claimed in the main patent, or a diazotised aniline-sulphonic acid is combined with 1 mol. of a middle component, the intermediate product is diazotised and combined with 1 mol. of a second middle component, the product is diazotised and combined with 1 mol. of 2-amino-5-naphthol-7-sulphonic acid, and again diazotised and combined with 1 mol. of resorcinol. *m*-Toluidine, *p*-xylydine, 3-amino-4-methoxy-1-methylbenzene, 1-naphthylamine or its 6- or 7-sulphonic acid, 1-amino-2-naphthol ethyl ether or its 6- or 7-sulphonic acid, and 2-amino-5-naphthol-7-sulphonic acid are specially suitable middle components.—F. W. A.

Azo dyestuffs; Manufacture of new—and metal compounds thereof, and application of the dyestuffs and compounds in dyeing. O. Imray, London. From Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 110,066, Dec. 19, 1916. (Appl. No. 18,206 of 1916.)

A DIAZO-COMPOUND of the benzene or naphthalene series (particularly an *o*-hydroxy-diazo-compound, a diazo-salicylic acid or other diazo-carboxylic acid) is combined with a condensation product of a phenol (particularly resorcinol) or a naphthol (particularly a dihydroxynaphthalene) with aceto- or oxalo-acetic ester. The mordant dyestuffs produced give fast dyeings on animal fibres, and may be after-chromed, etc., and give valuable water-soluble metal compounds with copper, chromium, etc., compounds.—F. W. A.

[*Dyestuffs of the anthraquinone series; Manufacture of condensation products*—. A. G. Bloxam, London. From Durand et Huguenin S.A., Basle, Switzerland. Eng. Pat. 110,042, Oct. 31, 1916. (Appl. No. 15,533 of 1916.)

SEE Ger. Pat. 294,447 of 1913; this J., 1916, 1214. The amino compounds specified are dialkyl-phenylenediamines having no substituent in one amino group.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Various modes of combination of methyl alcohol in plants. Determination of pectin- and lignin-methyl alcohol in roots. Von Fellenberg. See XIXA.

PATENTS.

Yarns; Apparatus for moistening—. R. Jacobi, Nijmegen, Holland. Eng. Pat. 109,686, Oct. 31, 1916. (Appl. No. 15,509 of 1916.)

THE cops or cheeses of yarn are secured on pins mounted on carriers placed in frames, which can be pushed into the yarn-moistening chamber; this chamber is so constructed that the end walls of the frames form closures for the chamber when they are either pushed in or withdrawn from it. Air is moistened by means of a "Jacobine," and distributed through the yarn in the chamber, either by pressure or vacuum induced through the water sprays.—J. F. B.

Woollen and other textile fabrics; Waterproofing of—. J. L. Wahnrow, London. Eng. Pat. 109,691, Nov. 8, 1916. (Appl. No. 16,003 of 1916.)

A SOLUTION consisting of powdered alum, 2 lb.; sugar of lead, 2 lb.; gum arabic, 2 oz.; powdered lime, 2 oz.; washing soda, 2 oz., and water, 18 quarts, is filtered; the woollen or other fabric is dipped in the solution and dried, preferably by heated calender rolls.—J. F. B.

Coating fabrics or materials; Apparatus for—. S. Davies, London. Eng. Pat. 110,050, Nov. 21, 1916. (Appl. No. 16,675 of 1916.)

THE material, supported on an endless band, is coated by passing against the opening of a transverse container holding the coating liquid and provided with a knife or scraper. The container may be movable, and the apparatus may also include a receptacle and scraper for the removal of coating agent which may pass on to the endless band after the material to be coated has passed through the machine. In addition, the apparatus may include suitable dressing devices for the preliminary treatment of the material.—D. F. T.

Fabrics; Solution for waterproofing—. T. C. James, Chicago, Ill. U.S. Pat. 1,240,345, Sept. 18, 1917. Date of appl., Sep. 30, 1914.

ONE part each of lead acetate and powdered alum are dissolved in 25 times their combined weight of water and 3/8 part of gum arabic dissolved in an alcoholic medium is mixed with the solution.

—J. F. B.

Sulphite cellulose; Method of preparing—. C. Bache-Wüg, Portland, Me. U.S. Pat. 1,240,920, Sep. 25, 1917. Date of appl., Nov. 7, 1914.

WOOD in small pieces is boiled in a solution of calcium, sodium, or magnesium bisulphite, and a small quantity of sodium chloride (e.g., less than 5%) is injected during the boiling.—F. SP.

Cellulose; Process of preparing solutions of—. Z. Ostenberg, San Francisco, Cal., Assignor to International Cellulose Co., Reno, Nev. U.S. Pat. 1,242,030, Oct. 2, 1917. Date of appl., Apr. 7, 1916.

CELLULOSE is treated with a mixture of a chloride and sulphuric acid of more than 60% concentration.—F. SP.

Pulp for papermaking purposes and the like; Apparatus for washing—. S. Milne, Edinburgh. Eng. Pat. 109,594, June 19, 1917. (Appl. No. 8778 of 1917.) Addition to Eng. Pat. 107,410 of 1916 (this J., 1917, 959).

THE principle of washing described in the original specification, which consists in passing the pulp over one side of a wire cloth while applying sprays of water to the other side, is adapted to the washing drum of a hollander. The trough of ordinary construction is provided with a washing drum covered with wire cloth. The inner end of the drum is closed, while the outer end is open and abuts against a flange fixed to the side of the trough, the joint being packed with suitable material. The drum is mounted on a hollow trunnion at the outer end and a water pipe passes through the bearing, from which sprays of water are directed against the inner periphery at the portion where it is in contact with the pulp. The waste water flows out through a drain outlet in the flange.—J. F. B.

Acetylcelluloses; Modifying—. F. Knoevenagel, Heidelberg, Assignor to Knoll und Co., Ludwigshafen, Germany. U.S. Pat. 1,241,995, Oct. 2, 1917. Date of appl., Jan. 29, 1913.

SEE Fr. Pat. 453,835 of 1913; this J., 1913, 785.

Washing detergent compounds and modes of using the same. Eng. Pat. 109,846. See XII.

PATENT.

Manufacture of new azo dyestuffs and metal compounds thereof and their application in dyeing. Eng. Pat. 110,066. See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrous acid; Velocity of decomposition and dissociation constant of— P. O. Rây, M. L. Dey, and J. C. Ghosh. Chem. Soc. Trans., 1917, 111, 413—417.

A solution of nitrous acid of $N/32$ concentration was prepared by double decomposition of $N/16$ solutions of barium nitrite and sulphuric acid at 0°C ., and the velocity of decomposition was determined at 0° , 21° , and 40°C . respectively. The decomposition follows the course of a unimolecular reaction, the velocity constant being 0.00014 at 0° , 0.00022 at 21° , and 0.00057 at 40°C . The maximum concentration of nitrous acid obtainable at 0°C . is 0.185 N . Determinations of electrical conductivity at 0°C . gave a value of 6×10^{-4} for the dissociation constant of nitrous acid at this temperature. For the determination of nitrous acid the permanganate method was found to be more trustworthy than the urea method (compare Werner, this J., 1917, 1147).

Pyrophosphoric acid; Structure of— E. Balareff. Z. anorg. Chem., 1917, 99, 190—194. J. Chem. Soc., 1917, 112, ii., 467.

FURTHER evidence is given in favour of an unsymmetrical structure for pyrophosphoric acid. When orthophosphoric acid is dehydrated by boiling with SOCl_2 , the pyro-acid formed is always accompanied by metaphosphoric acid, whilst when SO_2Cl_2 is used, only the pyro-acid is obtained. Ethyl metaphosphate, prepared from ether and phosphoric oxide without heating, combines with ethyl orthophosphate at 185° — 190°C . forming the pyrophosphate. Ethyl metaphosphate does not combine with methyl orthophosphate, but methyl metaphosphate is formed by heating methyl pyrophosphate. Calcium pyrophosphate reacts with phosphorus pentachloride according to the equation $2\text{Ca}_2\text{P}_2\text{O}_7 + 6\text{PCl}_5 = \text{Ca}(\text{PO}_3)_2 + 8\text{POCl}_3 + 3\text{CaCl}_2$, and the strontium salt behaves in a similar manner.

Pyrophosphoric acid; Volumetric determination of— D. Balareff. Z. anorg. Chem., 1917, 99, 184—186. J. Chem. Soc., 1917, 112, ii., 506.

A SOLUTION of sodium pyrophosphate, acidified with a known quantity of sulphuric or hydrochloric acid, may be titrated with sodium hydroxide, the maximum redness of phenolphthalein being taken as the end-point. The indication is sharper in presence of sodium chloride. Sodium pyrophosphate solution may also be estimated by adding it to an excess of silver nitrate solution, collecting and washing the precipitate of silver pyrophosphate, and titrating the filtrate with thiocyanate. The silver cannot be replaced by lead. Formulae are given for the titration of ortho-, pyro-, and metaphosphoric acids in the same solution with sodium hydroxide, the indicators used being methyl orange, phenolphthalein, and silver nitrate-lacmoid (compare this J., 1917, 336).

Phosphates of calcium. Part IV. The basic phosphates. H. Bassett, jun. Chem. Soc. Trans., 1917, 111, 620—642. (See this J., 1907, 199, 317; 1909, 722.)

THE author gives the results of a phase-rule examination at 25°C ., and also at 100°C . and higher temperatures, of that portion of the system, $\text{CaO}-\text{P}_2\text{O}_5-\text{H}_2\text{O}$, lying between the regions where dicalcium phosphate and calcium hydroxide respectively are the stable solid phases. The chief experimental difficulties were due to the extreme slowness with which equilibrium is attained. It was found that two, and only two, phosphates of calcium more basic than dicalcium phosphate exist which can be in stable equilibrium with an aqueous solution at 25°C . (and probably at any temperature). These are tricalcium phosphate and hydroxyapatite ($\text{Ca}_3\text{P}_2\text{O}_7$) $_2\text{Ca}(\text{OH})_2$. The view of Cameron, Seidell, and Bell (this J., 1906, 120) that a series of solid solutions exists in this region of the system is shown to be incorrect. The range of existence of hydroxyapatite extends from markedly acid through neutral to markedly alkaline solutions. The nature of bone phosphate is discussed, and it is concluded that this is a mixture of hydroxyapatite and calcium carbonate with small amounts of adsorbed bicarbonates of sodium, potassium, and magnesium. It is probable that hydroxyapatite is the only calcium phosphate which can exist permanently under normal soil conditions. When superphosphate is added to the soil the hydroxyapatite formed by the "reversion" of the monocalcium phosphate is produced in a finely-divided state. Finely ground basic slag when added to the soil will also yield hydroxyapatite fairly quickly whether it contains tetracalcium phosphate, as has been suggested, or some other compound more closely related to hydroxyapatite. Earthy phosphorites and coprolites are most probably impure mixtures of hydroxyapatite and calcium carbonate, and this is in accord with the known fact that when extremely finely ground they give satisfactory results when used directly as fertilisers. Under the conditions which have led to the accumulation of phosphatic deposits, a certain amount of replacement of the hydroxyl of hydroxyapatite by chlorine or fluorine has occurred.

Potassium stannichloride; Simple method of preparing— J. G. F. Druce. Chem. Soc. Trans., 1917, 111, 418—419.

POTASSIUM stannichloride may be obtained by oxidising with chlorine a concentrated solution of potassium stannochloride or a solution of stannous chloride in a concentrated solution of potassium chloride made slightly acid with hydrochloric acid. 22 grms. of stannous chloride is dissolved in a concentrated solution of 16 grms. of potassium chloride, with addition of a few drops of concentrated hydrochloric acid. A slow stream of chlorine is passed into the solution for about 3 hours, a small quantity of concentrated hydrochloric acid is added, the solution is concentrated on a water-bath at 50° — 70°C ., and allowed to crystallise.

Hydrogen oxalates of the alkaline-earth metals. G. Bruhns. Z. anorg. Chem., 1916, 95, 191—224. J. Chem. Soc., 1917, 112, i., 534—535.

IN view of the uses of oxalic acid in analysis, and of the advantages of pure oxalic acid as a standard for volumetric solutions (this J., 1916, 908; 1917, 545), the conditions under which acid salts of the alkaline-earths are formed have been investigated. Dilute solutions of barium chloride yield with 2 mols. of oxalic acid a crystalline precipitate of the salt $\text{BaH}_2(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$, which is rapidly decomposed by cold water. One mol. H_2O is readily lost, even at atmospheric temperature in a

vacuum, whilst the other molecule is only driven off at 125° C. Solutions of progressively diminishing acidity yield the salts $\text{Ba}_2\text{H}_2(\text{C}_2\text{O}_4)_3 \cdot 3\text{H}_2\text{O}$ and $\text{Ba}_3\text{H}_2(\text{C}_2\text{O}_4)_4 \cdot 3\text{H}_2\text{O}$, all being similar in appearance. Titration with *N*/10-sodium hydroxide shows that a small part of the oxalic acid remains combined with the normal oxalate, even after prolonged boiling. When barium hydroxide solution is in excess, the precipitated barium oxalate contains an excess of barium. The error in titrating barium with oxalic acid, and conversely, is therefore considerable. Normal barium oxalate may contain more than $11\text{H}_2\text{O}$ when precipitated cold from barium hydroxide and oxalic acid, whilst the product from barium chloride and sodium oxalate may contain less than 1 mol., even from dilute solution. At 100° C. it only contains $\frac{1}{2}\text{H}_2\text{O}$. Strontium has less tendency to form acid salts. A salt, $\text{Sr}_2\text{H}_2(\text{C}_2\text{O}_4)_3 \cdot 2\text{H}_2\text{O}$, is obtained which is decomposed completely by cold water. Slow crystallisation from slightly acid solution, however, yields homogeneous crystals containing an excess of acid, which are only very slowly decomposed by water. Strontium chloride is more suitable than calcium chloride for addition in titration of oxalic acid under conditions which cause rapid precipitation. A *N*/10-solution of strontium hydroxide is very suitable for volumetric estimations of oxalic acid, care being taken that the alkaline solution is not in excess, which would cause the precipitate to retain strontium. The water of crystallisation varies, as in the case of other oxalates, with the conditions of preparation. The titration of oxalic acid in nitric acid solution is quite satisfactory in the presence of barium nitrate, and even of barium chloride.

Manganese salts; Reaction of—V. Macri. *Boll. Chim. Farm.*, 1917, 56, 377. *J. Chem. Soc.*, 1917, 112, ii., 511.

WHEN a solution containing manganese, even in very small proportion, is rendered slightly alkaline and shaken and treated successively with a few drops of alkali oxalate solution and of acetic acid, the liquid assumes a distinct and persistent rose red colour. The reaction is rendered more sensitive if the alkaline solution is boiled and then allowed to cool before the addition of oxalate and acetic acid, and also if one or two drops of hydrogen peroxide solution are added before the liquid is made alkaline. Salts of other metals do not interfere with the reaction, except that those giving coloured solutions, especially if present in marked proportion, may mask it.

Ferric hydroxide; Adsorption of sulphuric acid by—, and *formation of colloidal sulphur from sulphides*. E. Dittler. *Kolloid Zeits.*, 1917, 21, 27–28. *J. Chem. Soc.*, 1917, 112, ii., 443.

EXPERIMENTAL results are recorded which show that sulphuric acid is adsorbed by ferric hydroxide to such an extent that errors may be introduced in the estimation of sulphur in pyrites by Lunge's method. By the action of steam on pyrites and marcassite for prolonged periods, small quantities of colloidal sulphur are produced. It is suggested that native sulphur may in some cases have been formed by a similar action.

Silver peroxide and the valence of silver. H. C. P. Weber. *Amer. Electrochem. Soc.*, Oct., 1917. [Advance copy.] 10 pages.

THE brownish-black "silver peroxide" to which the formula $2\text{Ag}_2\text{O}_4 \cdot \text{AgNO}_3$ has been ascribed (Brown, this *J.*, 1916, 1217) forms a dark coloured solution in nitric acid. This solution retains its colour for 24–36 hours in the cold but at once decomposes on warming or on dilution; when cooled in liquid air it gives a yellowish crystalline mass which on melting reproduces a black liquid.

The addition of soluble chlorides induces rapid decomposition of the solution even at very low temperatures; the solution is without action on a solution of permanganate, persulphate, or chromate, but converts lead nitrate gradually into lead dioxide and manganese sulphate instantly into permanganic acid; ammonium salts, with the exception of the nitrate, cause the decomposition of dilute solutions of the "peroxide." The formula $2\text{Ag}_2\text{O}_4 \cdot \text{AgNO}_3$ accords satisfactorily with these facts if it is assumed that the silver in the former constituent is present in a form of high valency corresponding with such compounds as permanganates, chromates, and persulphates, and this assumption receives confirmation from experiments on the migration of the ions during electrolysis. When the nitric acid solution is electrolysed in a suitable apparatus, the dark coloured "peroxynitrate" ions are found to move towards the anode whilst simultaneously silver ions migrate towards the cathode; the relation between the amounts of silver travelling towards the anode and cathode respectively suggests that the oxidic compound is the silver salt of an argentic acid probably containing trivalent silver, a likely formula for the compound being $\text{Ag}(\text{AgO}_2)_2$, in which the silver in the cation and anion is respectively di- and tri-valent. The fact that no hydrogen peroxide is formed in the decomposition of the "peroxide" excludes the possibility of the double compound being a pernitrate or of its containing a true peroxide, and is in agreement with the structure now suggested.—D. F. T.

Hydrogen peroxide; Sensitive reaction of—depending on the formation of dihydroxytartaric acid. G. Denigès. *Ann. Chim. Analyt.*, 1917, 22, 193.

Two c.c. of 5% tartaric acid solution is mixed with 2 drops of 5% ferrous ammonium sulphate solution, from 0.1 to 2.0 c.c. of the solution to be tested is then added, and the mixture is treated with 5 drops of sodium hydroxide solution. If the test solution contained hydrogen peroxide, a violet coloration appears immediately. The reaction may be obtained with as little as 0.05 mgrm. of hydrogen peroxide.—W. P. S.

PATENTS.

Alkaline peroxide; Manufacture of—G. F. Jaubert. *Paris. Eng. Pat.* 101,709, Sept. 28, 1916. (*Appl. No.* 13,813 of 1916.) Under Int. Conv., Oct. 2, 1915.

ALKALINE peroxide, more particularly sodium peroxide, is obtained in very porous masses or lumps of low density, by slow oxidation of the melted metal. For instance, sodium is heated to about 300° C. in aluminium boats in a suitable retort through which passes a slow stream of a mixture of 90–95% of nitrogen and 5 to 10% of oxygen, free from carbon dioxide. It is necessary that the metal shall not actually burn, otherwise the peroxide is melted and formed in compact lumps. In this porous form the peroxide is particularly suitable for the treatment of vitiated air, in respirators, etc.; the activity of the sodium salt in this respect is increased by addition of a little potassium and still more by the addition of small quantities of catalysts such as nickel, copper, cobalt, or manganese oxides. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the

Patents and Designs Act, 1907, to Eng. Pats. 20,003 of 1891, 8865 of 1904, and 7641 of 1907; this J., 1892, 1005; 1904, 833; 1907, 1008.)

—B. V. S.

Magnesium chloride; Production and utilisation of —. G. H. Bailey, G. W. A. Foster, and The British Aluminium Co., Ltd., London, Eng. Pat. 109,996, Sept. 30, 1916. (Appl. No. 13,934 of 1916.)

ANHYDROUS magnesium chloride is prepared by the action of chlorine or of waste gases containing chlorine on a mixture of magnesium and carbon at 750° to 800° C. The magnesia-carbon mixture is prepared in briquette form by moulding a mixture of magnesite or magnesia and carbon, cemented together with tar, and heating to 1000°—1200° C., out of contact with oxygen. The proportions are such as to leave 40 parts of magnesium oxide to 12 parts of carbon, as required by the equation:—

The magnesium chloride is formed in molten condition and may be collected as such or used for maintaining the supply of chloride to an electrolytic apparatus for the production of metallic magnesium; in the latter case the chlorine produced by the electrolysis is utilised to react with fresh supplies of the magnesia-carbon mixture. A suitable apparatus for continuous working of the process is described.—B. V. S.

Aluminous compounds; Treatment of —. H. Spence, W. B. Llewellyn, and P. Spence and Sons, Ltd., Manchester, Eng. Pat. 109,998, Oct. 2, 1916. (Appl. No. 13,958 of 1916.)

POWDERED ignited alunite is mixed with water and treated with sulphur dioxide, preferably at about 40° C. In order to prevent the formation of double basic aluminium-alkali sulphate the solution is treated if necessary with milk of lime to reduce the excess of acid, above what is required by the alkalis and alkaline-earths present, to a proportion of about 0.9 mol. of acid to 1 mol. of alumina; it is then filtered and boiled to drive off sulphur dioxide; air is excluded to avoid oxidation and precipitation of iron salts. A pure basic aluminium sulphate separates, easily soluble in acids and yielding practically pure alumina on heating.—B. V. S.

Calcium or other metal cyanamide; Process of making —. J. H. Reid, Newark, N.J. U.S. Pat. 1,241,020, Sept. 25, 1917. Date of appl., June 28, 1915.

A MOLTEN carbide, e.g., calcium carbide, is introduced into an atmosphere of nitrogen and the association of the ingredients maintained until combination to cyanamide is complete.—F. Sr.

Iodine; Manufacture of —. V. Vincent, Quimper, France. Eng. Pat. 101,871, Oct. 2, 1916. (Appl. No. 13,979 of 1916.) Under Int. Conv., Oct. 16, 1915.

VIII.—GLASS; CERAMICS.

Kaolinite; Molecular destruction of —by heat. A. M. Sokolov. Kryst. Min., 1915, 55, 195—196. J. Chem. Soc., 1917, 112, ii., 492.

KAOLINITE from Gluchov was heated for periods

of one to five hours at temperatures from 200° to 1000° C., and the loss of water determined. The residue was digested for two hours with 16% hydrochloric acid, and the soluble alumina determined. The quantities of soluble alumina formed after ignition for one hour at the temperatures mentioned were: 300°, 2.12; 400°, 2.08; 600°, 28.46; 700°, 32.30; 800° C., 31.66%. The quantities of waterlost were: 300°, 0.72; 400°, 0.67; 600°, 10.49; 700°, 11.92; 800° C., 12.99%. With more prolonged heating, slightly higher results were obtained. From the residue a weak alkali solution extracts soluble silica. At 800° C., the kaolin molecule is completely broken down into its component oxides.

Glass tubes; Manufacture of —. The British Thomson-Houston Co., Ltd., London, From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 109,813, Sept. 27, 1916. (Appl. No. 13,741 of 1916.)

IN an apparatus of the type described in Eng. Pat. 17,602 of 1913 (this J., 1914, 831), for the continuous manufacture of glass tubing, a float, 100, in the crucible, 80, is provided with depending arms

carrying a cross-bar, 102, through which compressed air is supplied by the pipe, 103, to the nozzle, 101, and thence to the tubing, R', which is drawn through the annular opening in the float. —W. F. F.

Glass bulbs [containing a gas in solution]; Method of sealing —. A. J. Loopsinger, Providence, R.I., Assignor to General Fire Extinguisher Co., New York. U.S. Pat. 1,241,229, Sept. 25, 1917. Date of appl., Mar. 11, 1916.

A GLASS bulb having a long neck and containing a gas in solution, is placed in a closed receptacle and sealed under pressure.—F. Sr.

IX.—BUILDING MATERIALS.

PATENTS.

Limckiln. P. J. Dauernheim, St. Louis, Mo. U.S. Pat. 1,240,950, Sept. 25, 1917. Date of appl., June 21, 1915.

AN internal furnace of ceramic material is provided with a fuel opening, grate bars, and ashpit, and a series of fire-holes extend through its walls into the annular space between the furnace and the outer casing of the kiln. A horizontal water drum is provided in each side wall of the furnace just below the grate bars, and a larger drum in the crown of the furnace. The drums are connected by vertical tubes adjacent to the fire openings

to reinforce the walls and protect them from excessive heat. A steam drum located outside the kiln at a higher level is connected by pipes to the water drums.—W. F. F.

Plaster and mortar; Process of making—

W. C. Hay, Los Angeles, Cal. U.S. Pat. 1,241,211, Sept. 25, 1917. Date of appl., Oct. 19, 1916.

SLAKED lime is aged to form lime putty, which is then thinned with water and violently agitated to aerate it. Sand is caused to move in a continuous stream and a "hardening agent" is fed into it at a predetermined rate. The thinned lime putty is then added at a predetermined rate, and finely-divided fibre is blown into the mixture. —W. F. F.

Cement paint. Eng. Pat. 109,951. See XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Soft gray iron; High sulphur in—T. Mauland. Amer. Foundrymen's Assoc., Sept., 1917. Met. and Chem. Eng., 1917, 17, 383.

CASTINGS containing 0.12% S may be good, strong and soft, while others containing less than 0.09% are hard; in the former cases, the oxygen content is usually low.—T. H. B.

Iron castings; Porosity of—R. Namias. Monit. Scient. 1917, 61, 217–218.

POROSITY of castings is caused by the imperfect escape of gases from the metal. High phosphorus content in cast iron conduces to fluidity and thus to the easy escape of gases. Samples cut from two castings which were sound in the lower and porous in the upper parts, contained in the porous parts 0.382% and 0.775% P and in the sound parts 0.462% and 1.166% respectively. All other constituents were present in substantially the same amounts in both parts of the castings. The differences observed are attributed to liquation or preferably to the removal of phosphorus by the action of the basic constituents of the slag. The slag should have a high degree of fluidity to permit rapid separation, as the evolution of gas might be due to the oxidation of carbon by oxides of iron and manganese in the slag, and this would be intensified by longer contact. Quicklime is preferable to limestone as an addition in the cupola to obtain a suitable slag.—H. J. H.

Malleable iron annealing; Carbon losses in—

J. B. Deisher. Amer. Foundrymen's Assoc., Sept., 1917. Met. and Chem. Eng., 1917, 17, 383.

THE safe annealing temperatures are from 1450° to 1650° F. (about 790° to 900° C.) for pot ovens and from 1500° to 1700° F. (about 820° to 930° C.) for muffle ovens. The best practice is to bring the castings to the highest temperature at the beginning of the anneal and maintain that temperature until the carbide is dissolved, then drop to 1400° F. (760° C.) to precipitate graphitic carbon. The conversion rather than removal of carbon produces ductility.—T. H. B.

Electrolytic pickling process and its effect on the physical properties of iron and steel. J. Coulson. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 7 pages.

TEST specimens of steel springs, drill rod, tempered steel, Bessemer and cold-rolled steel rods were exposed either as anode or cathode, or to ordinary chemical action, in a solution of 27% sulphuric acid at 60° C. On submitting to oscillating stresses all the springs pickled chemically and electrolytically as cathode broke during the preliminary test,

which consisted of a continuous strain for 12 hours, and gave a fracture showing a crystalline structure resembling that of glass-hard steel. No difference appeared to exist in the properties of anodically treated samples and the original tempered metal either before or after a sand-blasting treatment. On submitting to bending tests, samples which had been pickled chemically and electrolytically as cathode showed fatigue and cracks much sooner than untreated test pieces or than those treated electrolytically as anode. The Brinell test for hardness indicated an increase of about 5% for specimens pickled as cathode, while no material change was noticeable with any of the others. The tensile strength, percentage elongation, and reduction of area under stress were also unfavourably affected by the chemical treatment or electrolytic treatment as cathode, the greatest modification being obtained with high carbon steel, whereas anodic pickling did not impair the physical properties. The fractures were similar in the cases of the original metal and that anodically pickled, while the cathodically treated samples gave an irregular break with a dark centre encircled by a well-defined bright band showing the depth to which the hydrogen penetrated the metal. The hydrogen appears to form an alloy with the metal, the rate of penetration increasing with the current density, and in the case of ordinary chemical pickling absorption takes place more slowly. Test specimens made brittle by pickling either chemically or electrolytically as cathode were restored to their original condition by annealing or by repickling electrolytically as anode, thus indicating that anodic treatment either alone or after electrolysis as cathode is the most effective way of cleaning iron and steel without impairing the physical properties.—J. N. P.

Steels; Heterogeneity of—G. Charpy and S. Bonnerot. Comptes rend., 1917, 165, 536–540.

By etching steel with a cupric reagent and dissolving the deposited copper in ammonia, pearlite shows in white, and ferrite in dark patches; hence the specimens give a "negative" image compared with that produced by iodine, or nitric or picric acid. The progressive deformation of the dendritic structure of steel in the rolling process was investigated by means of the cupric etching solution, which gives sharper contours than the other reagents. As heat treatment does not modify the microstructure of steel to any extent, the degree of rolling can be ascertained approximately even after heat treatment, if the original dimensions of the dendrites are known. The finer dendrites found near the surface of cast steel do not vary much in size, but those formed in the central zone of ingots increase considerably with the size of the ingot. Even in medium size ingots of pure steels which do not exhibit pronounced segregation, very large variations may frequently be observed in the size of the dendrites of the peripheral and the central zones.—W. R. S.

Vanadium in alloy steels; Role of—G. L. Norris. Amer. Soc. for Testing Materials, June, 1917. Eng. and Min. J., 1917, 104, 557–558.

THE author contends that the beneficial effects of vanadium in steel are not due to its power of removing oxygen and nitrogen, but that its value is due to its presence as an alloying element and to its influence on the other constituents. Only a few hundredths per cent. combine with the ferrite; nevertheless the mechanical properties of the latter are thereby improved. Nearly all the vanadium is found in the pearlite as an iron vanadium carbide in ternary, and as more complex carbides in quaternary steels. Vanadium progressively replaces iron in cementite until, with 5% vanadium in the steel, the whole of the iron has been replaced. Vanadium carbide has a

strong tendency to produce sorbitic and even troostitic pearlite. It is not so soluble as iron carbide, hence a higher temperature is required to ensure an austenitic condition prior to quenching. The effects of vanadium increase until about 1% is present; with 3% carbon steel is actually softened by quenching. High-speed steel tools withstand higher temperatures if 0.3 to 2.5% of vanadium is present; 0.2% is greatly beneficial in carbon-steel tools. As regards cast steel, 0.15% increases the elastic limit of annealed castings 25–30% without lowering their ductility; this proportion is now frequently added to locomotive frame metal. For heat treatment, vanadium steel has shown its superiority over ordinary steel. There is probably a great future for quaternary vanadium-steel (especially heat-treated) castings.—W. R. S.

Steel springs; Prevention of brittleness in electroplated—. T. S. Fuller. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 9 pages.

THE breaking strength of untreated test springs was found to vary from 319 to 439 lb., while before breaking the springs stretched to two or three times their original length; after plating in a copper cyanide solution for $\frac{1}{2}$ hour, the value fell to 69–137 lb., and there was very little stretching before breaking; after pickling for 3 mins. in 20% sulphuric acid solution, the value was 198 lb., and after a treatment of one hour, 29 lb. Samples which were coated with tin by dipping in rosin and then in the molten metal at 260–300° C., and afterwards copper-plated, showed a breaking strength of 300–352 lb., but when pickled in acid before tinning, a value of 22–31 lb. resulted. Preliminary treatment by sand-blasting did not, however, lower the breaking strength. The protective action of the tin in preventing embrittlement is apparently due to its being impervious to atomic hydrogen.—J. N. P.

Iron-copper; The system—. R. Ruer and F. Goerens. Ferrum, 1916, 14, 49–61. J. Chem. Soc., 1917, 112, ii., 474. (Compare Ruer and Fick, this J., 1913, 1111.)

WITH the object of elucidating certain discrepancies, particularly in regard to the behaviour of the molten metals, the authors have melted electrolytic copper and iron (m. pt. 1528° C.) in porcelain tubes in an atmosphere of nitrogen, and have investigated the alloys thermally, micrographically, and magnetically. A separation of layers actually occurs when the pure metals are melted together. On the other hand, that portion of the freezing-point curve which lies between the end-points of the mixture gap (24% Cu at 1450° and about 85% Cu at 1375° C.) is definitely shown not to be horizontal; the observed discrepancy cannot be attributed to under-cooling. On solidification, therefore, the system Fe-Cu shows the behaviour of a system of three or more substances. The absorption of impurities during the process of melting, in amount sufficient to explain the phenomena, could not be established.

Zinc dust precipitation [of gold, silver, and copper from cyanide solutions]; Efficiency of—. W. J. Sharwood. Amer. Inst. Min. Eng. Met. and Chem. Eng., 1917, 17, 437.

THEORETICALLY, 1 unit weight of zinc should precipitate 6.03 units of gold, 3.30 units of silver, or 1.93 of copper; but laboratory tests with commercial zinc dust usually show an efficiency of 30 to 60%. Extremely fine and pure zinc dusts prepared by redistillation of spelter have shown efficiencies of 75% and higher, especially in presence of 1 or 2% of lead; coarse or granular zinc gives low results. The working efficiency on a large scale may be a mere fraction of 1% in the case of low-grade gold solutions, much zinc being

wasted in side reactions; a 50% efficiency may be approached with rich silver solutions. A practical example of mixed precipitation showed an efficiency of 0.39% for gold, 4.75% for silver, and 3.93% for copper, the figures being obtained by dividing the weight in lb. by the electro-chemical equivalent, dividing the quotient by the number of equivalents of zinc used, and multiplying by 100; the zinc dust was assumed to contain 90% of the metal.—T. H. B.

Copper; Electrolytic recovery of—and of sulphuric acid from copper mill pickling solutions. J. L. Jones. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 8 pages.

THE solution obtained in the removal of scale from copper by treatment with heated dilute sulphuric acid, which becomes saturated with copper sulphate, is treated electrolytically in order to recover both the copper and the acid, the latter being then available for further pickling. The cathodes consist of steel plates which are given a preliminary coating of copper by means of a cyanide bath, and the anodes of sheet lead. The recovery tanks are made of wood with a lead lining and arranged in cascade in a cement pit provided with a sump for the accumulation of leakage. The series system of electrical connections is used, with parallel circulation of the electrolyte across the face of the electrodes. The solution is regenerated until the acid content is about 20% and the copper 1%, a current efficiency of 72% being obtained. Good results are also obtained by a continuous circulation of the solution through the pickling and recovery vats, whereby the acid content is maintained at about 14%, and the copper at 3.5%.—J. N. P.

Brass; Metallography of—Development and reabsorption of the β -constituent in alloys which are normally of the α -type. C. H. Mathewson and P. Davidson. J. Amer. Inst. of Metals, 1917, 11, 12–63.

TO determine the effect of the metastable β -constituent on the strength and ductility of α -brass in the worked and annealed conditions, α -brasses containing 70, 67, and 65% Cu, respectively, prepared from pure copper and zinc, were over-heated to produce a prominent network of the β -constituent and then cooled or annealed to effect re-absorption of this network to a different extent in each specimen. In the 70% alloy, no β -constituent was developed by annealing at 900° C. for 15 mins. and quenching in water, but the ductility of the alloy was considerably reduced. By annealing at 920° C. before quenching, partial fusion occurred and irregular results were obtained. The ductility was considerably increased by rapid air-cooling after annealing at 920° C., owing to the re-development of the α -phase throughout the mass. With the 67% alloy, little change in strength or ductility was effected by quenching from 880° C., owing to the non-retention of the β -phase in the quenched specimens. By air-cooling from 880° C., the tensile strength was decreased by 3000 lb. per sq. in. and the elongation (on 2 in.) increased by 3 percentage units, this being in accord with the structural evidence showing that the β -network had become more or less obliterated. A further decrease in tensile strength, due to the disappearance of the β -constituent, was obtained by cooling the alloy from 880° C. to 450° C. at the rate of 50° per min. The 65% alloy, in the "dead soft" condition, had a tensile strength between 41,000 and 42,000 lb. per sq. in. and an elongation of 80% on 2 in. By annealing and quenching at 790° C. the strength was increased by 5000 lb. per sq. in. and the elongation decreased by 16 percentage units; these effects were accompanied by the development of a distinct network

of the β -constituent, the proportion of which increased with the quenching temperature until, by quenching from 850° C., the tensile strength was further augmented by 3000 lb. per sq. in. and the elongation diminished by 1 percentage unit. These changes in strength and ductility were found to depend on the presence of the β -constituent in the form of a well-developed network around the α -grains, rather than on the mere presence of a moderate proportion of this constituent in the alloy. Since partial destruction of this network had a greater effect in raising the elongation than in lowering the tensile strength, an attempt was made to effect a combination of high strength and high elongation by quenching at a high temperature, to develop the β -network, and then annealing at a low temperature to effect granulation of the latter; a tensile strength of 46,000 lb. per sq. in. and an elongation of 70% were obtained by quenching at 820° C. and annealing for 1 hr. at 450° C. In further considering the possibility of increasing, by this means, the strength of α -brass for purposes where extreme ductility is unnecessary and cold-working undesirable, the tensile properties of 65/35 brass in which the β -constituent had been developed intentionally were determined after cold rolling and after cold working followed by light annealing. In the latter case, the tensile strength of the quenched (β -containing) alloy, which was originally 10,000 lb. per sq. in. higher than that of the slowly cooled (α) material, still remained 9000 lb. per sq. in. higher than the latter after very light annealing at 300° C., and the β -containing alloy was then considerably stronger and only slightly less ductile than the plain α -alloy. As a preliminary to the above work, the equilibrium curves of that part of the copper-zinc system covering the range of commercially important alloys were investigated and developed sufficiently to permit a useful calculation of the proximate composition of any pure brass in a state of equilibrium within the temperature range 500°–900° C.—W. E. F. P.

Brasses of the Muntz metal type: Corrosion of — H. S. Rawdon. Amer. Inst. Metals, Sept., 1917. Met. and Chem. Eng., 1917, 17, 382.

BRASS of the type Cu 60, Zn 40%, often becomes very weak and brittle when exposed to electrolytic action, particularly in sea water. Examination of the microstructure shows that the zinc-rich constituent is leached out leaving a powdery skeleton of copper. Later, the second constituent may be attacked. Conditions which affect the rate of corrosion are the microstructural composition of the alloy, contact with strongly electro-negative metals, adhering deposits of basic zinc chloride resulting from corrosion, thoroughness of annealing, temperature of the electrolyte, and stresses to which the alloy is subjected.—T. H. B.

Lead: Use of salt in the metallurgy of — O. C. Ralston, C. E. Williams, M. J. Udy, and G. J. Holt. Bull. Amer. Inst. Min. Eng., Aug., 1917. Met. and Chem. Eng., 1917, 17, 437.

Two methods are available for oxidised ores of lead; in one the lead is leached out with a saturated solution of salt acidified with sulphuric acid, followed by either electrolytic or lime precipitation; in the other, the ore is mixed with salt, and treated in a blast roaster or reverberatory furnace at 800° C. or higher. Lead chloride fumes are formed and caught in a Cottrell electrical precipitator, and the lead chloride finally reduced with lime and carbon; the calcium chloride slag which is formed can be used instead of sodium chloride in the process, and in this way from 50 to 75% of the chlorine is recovered. For oxidised lead

ores containing precious metals or copper, the leaching process can be used after a chloridising roast at slightly over 600° C. The volatilisation method is applicable to sulphide ores, but precious metals and copper cannot be extracted; these may be leached out after a chloridising roast, which is, however, more difficult to effect than with oxide ores. The volatilisation process also promises to be a suitable treatment for oxidised silicious lead ores, though neither of the salt processes seems to offer a solution of the "complex sulphide" problem.—T. H. B.

Antimony: Electrolytic production of — direct from stibnite ore. D. J. Demorest. J. Amer. Inst. of Metals, 1917, 11, 83–87.

IN a process by which antimony was produced at the rate of 800 lb. per day, stibnite (Sb_2S_3) was dissolved in an 8% solution of sodium hydroxide or sulphide and the solution electrolysed while circulating between iron electrodes, the cathodes being perforated to facilitate attachment of the deposit. A current density of 7 amp. per sq. ft. at 2.7 volts was employed, and a current efficiency of 76% obtained. The deposited antimony was free from "sprouting," firmly adherent, but easily stripped, and of great purity (S 0.02 and As 0.01%, with traces Fe but no Pb). Regeneration or renewal of the electrolyte was necessary as soon as the weights of antimony deposited and sodium hydroxide used became equal, since the solution then contained 4% of sodium thio-sulphate and 2% of sodium sulphide and commenced to attack the anodes by converting them into iron sulphide. Successful regeneration was effected on a small scale by evaporating the solution to dryness, roasting the residue to form sodium sulphate, and heating the latter with coal to produce sodium sulphide for use in treating fresh ore.—W. E. F. P.

Alloys: The hardness of — P. Ludwik. Z. Ver. Deut. Ing., 1917, 547–554. Engineering, 1917, 104, 444–445.

VARYING quantities of different metals were added to copper, tin, lead, zinc, and aluminium, and the hardness of the resulting alloys was ascertained by the Brinell test. In the case of copper addition of 1% of tin increases the hardness by 10%; 10% increases the hardness to twice, 15% to three times its value; annealing of the bronzes does not affect these figures much. The further addition of zinc to Cu-Sn further increases the hardness of the bronze, but much less than tin would do. Zinc alone added to copper augments its hardness slightly, but with 35% of Zn the hardness curve of the alloy rises suddenly (malleable brass). The hardness of brass is increased more by the addition of Sn, and also of Al (durana metal), than that of copper is; such bronzes are more brittle, however, and become soft on annealing. The addition of up to 8% of Al exercises little effect on the hardness of copper; higher percentages are more effective than Sn. Ni hardens copper less than Sn and Al do, Mn ranks between Ni and Sn in this respect, 15% of Mn being equivalent to 5% of Sn. Both Pb and Bi decrease the hardness of copper. Mg proved by far the most effective hardener of all the metals investigated. The hardness of tin is increased to twice its value by the addition of up to 15% of Pb; more lead makes the tin softer (soft solder). Cu has a stronger hardening effect on tin than lead in all proportions; Sb behaves like Cu, and 15% of Cu or of Sb imparts to tin three times its original hardness. Both Cu and Sb together (bearing metal) have a still greater hardening effect; Sb and much Pb added together give a softer bearing metal. Mg and Al have very strong effects; 0.5% of Mg makes the tin twice as hard. The addition of

1—8% of Sn increases the hardness of lead threefold, 15%—30% of Sb fivefold. Tin also hardens the lead, but much less; in ternary alloys of Pb-Sb-Sn the effect of Sb shows only at high percentages. Bi ranks below tin as hardener of lead. Cd has a much stronger action, surpassing even Sb, and Mg again the strongest; 0.5% of Mg increases the hardness of lead threefold. The presence of a little lead or tin renders zinc only a little harder; higher percentages of Sn make zinc (and also aluminium) softer. Ternary alloys of Zn-Sn with Cu or Al, and quaternary alloys with Cu and Sb, show this softening in a more pronounced way, whilst addition of Sb and especially of Cu to Zn renders the zinc harder; Zn with 4% of Cu has twice the hardness of Zn. Annealing effects little in these cases. An addition of 0.25% of Mg hardens the Zn as much as 4% of Cu. Cd stands next to Mg as a hardening agent of Zn; but the hardening effect of Cd reaches its maximum with only 4%, and the Al curve resembles that of Cd in alloys with Zn. Al is little affected in its hardness by the addition of Sn, above 4% of which rather softens it. Cu hardens Al, but Al-Cu is little influenced by tin. Zn has likewise a hardening effect on Al, weaker than that of Cu, however. Mg proves also the most efficient hardening agent of Al (magnalium); its effect in ternary alloys is less pronounced than in the case of other metals. The alloys of Al with Cu and Mg and, further, with Mn (duraluminium) are very hard, and annealing further increases the hardness of these alloys, as also of Al-Zn and Al-Cu alloys. There is a gradual increase in the hardness of Al-Cu alloys, amounting, e.g., to 17% when they are kept for three weeks at ordinary temperature.

Non-ferrous light metal scrap; Briquetting of —. A. L. Stillman. Amer. Inst. Metals, Sept., 1917. Met. and Chem. Eng., 1917, 17, 381.

MOST white metals and brasses can be welded together into "heavy scrap" having a sp. gr. from 65 to 85% that of the corresponding ingot metal. This is effected by multi-stage compression, moderate in its first stages, to interlock the fragments and expel entrapped air, and increasing to a final pressure of 33,000 lb. per sq. in. Fluxes or binders should not be used, unless the highest available pressure is insufficient to cause cohesion.

—T. H. B.

Rhodium; Action of oxygen on —. A. Gutbier, A. Hüttlinger, and O. Maisch. Z. anorg. Chem., 1916, 95, 225—246. J. Chem. Soc., 1917, 112, ii., 483.

WHEN rhodium is heated in air or oxygen at temperatures from 600° to 1000° C., the product is always the oxide, Rh_2O_3 , the rate of oxidation increasing rapidly with the temperature. Above 1150° C., the oxide is completely decomposed, the metal being obtained. The oxide, Rh_2O_3 , is greyish-black. The previously recorded formation of lower oxides is due to incomplete oxidation.

Metals; Search for two unknown —. M. Gerber. Monit. Scient., 1917, 61, 73—81, 121—127, 169—177, 219—226.

In the periodic classification of Mendeléeff there are vacancies for two elements with atomic weights about 99 and 187, which the author supposed might accompany, unsuspected, molybdenum (96) and tungsten (184) in minerals. Slight differences in chemical behaviour were found in specimens of tungstic acid prepared from different sources, and a complexity of the element tungsten was inferred. The abnormal specimens showed spectra identical with normal tungsten compounds. Similar results were found with molybdenum com-

pounds, so that the spectroscopic evidence negated the idea of complexity of tungsten and molybdenum. The author suggests the existence of isotopic forms of these elements, after the analogy of lead.—H. J. H.

PATENTS.

Iron ore process; Direct —. P. H. Ledeboer. London. Eng. Pat. 109,952, May 23, 1917. (Appl. No. 7396 of 1917.)

IRON ore is finely crushed and washed in a current of water to remove argillaceous material, including most of the phosphorus which the ore may contain. The ore is then converted into magnetic oxide by roasting it with a small quantity of carbon, carbonaceous material, or reducing gas. If sulphur is present it must previously be removed by electromagnetic separation or by raising the temperature sufficiently to expel it. Traces of phosphorus, arsenic, etc., may be removed by further magnetic separation. The pure magnetite thus obtained is mixed with coke, coal, anthracite, charcoal, sawdust, molasses, or the like, and heated to dull redness in a reducing furnace. The partly reduced material is transferred to a second reducing furnace at a higher temperature, through which a current of water-gas or the like is passed. The pure reduced iron is then transferred to a furnace heated by producer gas or water-gas, the reducing flame of which plays on the metal and passes downward to the underside of the hearth. The heated iron is pressed into blocks which may then be used for the production of iron or steel of any desired quality.—W. F. F.

Iron or steel; Process and solution for the treatment of —. A. Hayes. New York, Assignor to Carnot Development Corporation. U.S. Pats. (A) 1,241,112 and (B) 1,241,113, Sept. 25, 1917. Date of appl., Mar. 31, 1916.

(A) Iron or steel is heated and quenched in a hot solution of sal ammoniac, common salt, a substance capable of yielding fluorine, and "a reagent."
(B) The quenching solution consists of hydrochloric acid, free chlorine, and a substance capable of yielding fluorine, with or without sal ammoniac and sodium chloride.—W. F. F.

Lead; Extraction of — from its ores or lead-containing materials. H. L. Sulman and H. F. K. Picard. London. Eng. Pat. 109,817, June 30, 1916. (Appl. No. 9228 of 1916.)

ORES or other materials containing lead in the form of sulphate, or other form which may easily be converted into sulphate, e.g., by roasting, are treated with hot saturated brine to dissolve the lead sulphate. The formation of sodium sulphate, which would render the brine unfit for further use, is avoided by adding an equivalent amount of calcium chloride, insoluble calcium sulphate being thereby produced. The calcium sulphate and residues are removed by filtration, and the lead precipitated from the solution as carbonate by the addition of dry powdered sodium carbonate. The lead carbonate is then removed by filtration, and the solution may be used over again. Alternatively, the lead sulphate may be dissolved by brine, the lead precipitated by sodium carbonate or sodium sulphide and removed by filtration, and the liquor subsequently treated with calcium chloride to precipitate calcium sulphate which is removed by filtration and the solution used over again. If the ore contains zinc sulphate, this is dissolved by the brine, but may be retained in solution by adding sodium carbonate in quantity

sufficient to precipitate the lead carbonate only. Zinc carbonate may be precipitated by a further addition of sodium carbonate after the lead carbonate has been removed by filtration. If silver is also present the zinc sulphate is first removed by leaching, the residue treated as above for the recovery of lead, and the final residue treated with cyanide for the recovery of silver.—W. F. F.

Separator; Electromagnetic —. A. F. Hallimond and W. G. Fletcher, London, Eng. Pat. 109,857. (Appl. Nos. 14,629, Oct. 14, 1916, and 5054, Apr. 10, 1917.)

THE material to be separated is fed from a hopper on to a rotating disc having gaps at intervals, the feed being stopped automatically, when the gaps are passing the hopper, by a cam-operated sliding valve. A series of fixed magnet poles are provided above the disc, and a commutator cuts off the supply of current to the magnets as the gaps pass under them, so that the attracted material is discharged through the gaps to suitable receptacles beneath. In an alternative form the disc is replaced by a horizontal drum on to which the material is fed on its rising side. The magnetic field is cut off when a pocket in the periphery of the drum passes below the magnet so that the separated material is discharged into the pocket. This material is discharged from the pocket when it reaches the lowest point in its rotation. In another form the material is fed on to a horizontal endless conveyor passing below the magnet, the return portion of the conveyor being parallel and just below. Two gaps are provided in the conveyor, and are arranged to register when just below the magnet, so that when the field is cut off, the magnetic material is discharged through both gaps into the receiver below.—W. F. F.

Metalliferous ores; Process of concentration of —. S. I. Clawson, Salt Lake City, Utah. U.S. Pat. 1,240,824, Sep. 25, 1917. Date of appl., Jan. 2, 1914.

THE pulverised ore is mixed with a saline solution, and gas and oil are injected. The mixture is discharged into a closed separating chamber under pressure and the concentrate is withdrawn at the opposite side of the chamber. The surplus gas under pressure is also withdrawn from this side of the chamber and conveyed back to the point of injection to be used again.—W. F. F.

Welding-electrode and process of welding. Process for electric welding. P. A. E. Armstrong, Assignor to W. L. Clark and A. H. Adams (The Quasi-Arc Co.), New York. U.S. Pats. (A) 1,241,893, and (B) 1,241,900, Oct. 2, 1917. Dates of appl., Mar. 10 and Mar. 23, 1915.

(A) AN electrode for depositing metal consists of a metal tube with inner and outer coatings of insulating, slag-forming material. The outer coating melts at a higher temperature than the inner coating and acts as a protecting shield for the molten metal. The inner coating may contain an alloy, such as ferromanganese, which it is desired to add to the metal of the electrode. (B) Manganese-steel is deposited on work consisting of manganese-steel by an electrode of that material coated with insulating material which acts as a slag when fused. The electrode is maintained in contact with the molten metal but not with the work, and the deposited metal is cooled by a stream of water.—W. F. F.

Case-hardening material and process of making same. A. O. Blaich, Assignor to A. O. Blaich Co., Chicago, Ill. U.S. Pat. 1,241,909, Oct. 2, 1917. Date of appl., Jan. 29, 1917.

CARBON granules are impregnated with a solution

of soda ash and dried at a temperature at which the soda ash is unaffected. The granules are then sprayed with oil to coat their surfaces, and mixed with pulverised calcium or barium carbonate.—W. F. F.

Zinc-extraction process. H. R. Hanley, Winthrop, Cal., Assignor to Bully Hill Copper Mining and Smelting Co. U.S. Pat. 1,241,966, Oct. 2, 1917. Date of appl., June 5, 1916.

ZIN-bearing materials are mixed with concentrated sulphuric acid so as to form a thick mud, which is dried and roasted at from 200° to 650° C., to eliminate arsenic, selenium, and other volatile elements, and convert the zinc compounds to sulphate, which is then extracted with water. After removing metals more electro-negative than zinc, the solution is electrolysed, thus depositing zinc and liberating sulphuric acid, until from 70% to 90% of the zinc sulphate is decomposed. The remaining electrolyte is evaporated until the dissolved salts are precipitated, and the sulphuric acid is separated and used for the treatment of fresh quantities of zinc ores.—J. N. P.

Melting-pot or crucible [for melting brass]. J. C. Henderson, Washington, D.C., Assignor to Driver Harris Co., Harrison, N.J. U.S. Pat. 1,241,971, Oct. 2, 1917. Date of appl., July 8, 1916.

A THIN-WALLED melting pot is cast from a highly refractory alloy containing chromium or a metal having similar properties, and nickel or other metal associated with iron in the periodic table having substantially the same atomic weight, these combined metals amounting to not less than 60% of the alloy. The walls increase in thickness towards the bottom and a refractory non-flaking coating not acted upon by molten brass is provided on the inner surface.—W. F. F.

Lead sulphide ores; Treatment of — [to produce basic lead sulphate]. P. C. H. West, London. Eng. Pat. 102,377, Nov. 16, 1916. (Appl. No. 16,414 of 1916.) Under Int. Conv., Nov. 24, 1915.

Leaching apparatus. U.S. Pat. 1,240,904. See I.

XI.—ELECTRO-CHEMISTRY.

Electro-chemical plant; The sub-station problem of —. J. L. McK. Yardley, Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 20 pages.

ELECTRICAL apparatus has now been largely developed in the direction of low-voltage, large-capacity designs such as is demanded by electro-chemical processes. Variations in the applied voltage which are of considerable magnitude in electrolytic processes, on account of variations in resistance during the progress of electrolysis, or through changes in the number of cells connected in the circuit, can be provided for by means of "boosters." With rotary converter units of 300 kilowatts, giving a voltage of 200 to 300, direct-connected alternating-current "boosters" have been developed so as to make it possible to vary the direct current voltage delivered by the rotary converter by 30 or 40 volts on either side of the

mean value obtained when operating upon a particular transformer tap. Small variations, such as those brought about by fluctuations in power supply, have been provided for by employing rotary converters with direct connected, synchronous, alternating-current "boosters," though, more usually, the voltage has been equalised by introducing more than the normal amount of reactance in the step-down transformers or more copper in the field coils of the rotary converters. Line variations in the rotary converter are also met by varying the strength of the field current, a typical range for such an installation as that mentioned above being 237½ to 262½ volts. In the aluminium industry, a direct current voltage of approximately 250 volts was formerly used, enabling about 40 cells each taking 6 volts to be connected in series, and making it possible to cut out individual cells without involving any appreciable voltage variation on the leads. An improved efficiency in aluminium electrolysis has now, however, been gained by employing a direct current voltage of 500 to 550. The maximum efficiency of the rotary converter is practically reached at 600 volts, above which the cost of apparatus and operation troubles increase largely. In the electro-deposition and refining of metals, such as copper and zinc, a voltage range of 2:1 is frequently, and 3:1 sometimes, encountered through withdrawals of large sections of the tank for the removal of the metal and treatment of the electrolyte. This large voltage range can usually be supplied more satisfactorily by an installation of "booster" rotary converters arranged by providing one or two taps on the primary or secondary of the transformer and by providing the necessary switching for quickly transferring the "booster" rotary converter from one tap to another. By this means an extreme variation of 2.5:1 can be arranged. An alternative is to employ motor generator sets with separate exciters, whereby a continuous change of voltage is possible.—J. N. P.

Mica; Electrical conductivity of—E. Branly. Comptes rend., 1917, 165, 450—455.

A SHEET of unpierced mica, 0.003 mm. in thickness, was interposed between two metallic discs with plane polished surfaces, and contact between the sheets was ensured by means of a gas compression pump acting on one of the discs, the other disc being supplied with weights. The pressure was measured by a mercury and an ethylene dibromide manometer in parallel. A source of continuous current, such as a thermo-electric pile with Bi-Ag elements, or a Daniell's cell, and a galvanometer, were also placed in the circuit. With a sheet about 0.003 mm. thick, the mica allowed the current to pass from a single thermo-electric element at an E.M.F. of 0.004 volt. The conductivity was often immediately complete, manifesting itself as soon as a slight pressure was put on the sheets. An insignificant shock, or a feeble oscillating discharge at a distance, brought about the passage of the current when the pressure was removed. When the thickness exceeded 0.004 mm. the conductivity did not show itself with an initial E.M.F. as feeble as that of a single thermo-electric element and an E.M.F. of at least 1 volt was required, the conductivity rising by jerks and being only slowly established. The actions of shock, and of electric discharge at a distance, were again like those on ordinary detectors as used in wireless telegraphy.—B. N.

PATENTS.

Selenium and like sensitive cells. M. Martinez. London, Eng. Pat. 109,486, Sept. 16, 1916. (Appl. No. 13,181 of 1916.)

A THIN sheet or granular layer of prepared and annealed selenium, or like material, is placed between opposite sources of light and heat, one of which is kept constant at a required intensity while the other is made variable so as to render the general resistance of the cell capable of adjustment. The granular layer is held between metallic electric conductors formed of netting, wire, or perforated metal. The selenium sheet is made by first granulating the material, and then forming it into a sheet between discs which are caused to move one on the other under pressure, and annealing the sheet at a temperature between 120° and 200° C. whilst between the discs.—B. N.

Furnaces; Electric—J. O. Boving, London. Eng. Pat. 109,465. (Appl. Nos. 12,687, Sept. 7, 1916, and 2807, Feb. 26, 1917.)

THE current is maintained constant in an electric furnace, by means of a hydraulic organ for modifying the position of the electrode conveying the current. The supply of fluid under pressure to the hydraulic organ is regulated by a valve actuated directly by the fluid pressure, and a balanced escape valve for the fluid is provided, its position being automatically adjusted by electro-magnets. The electro-magnetic arrangement is energised directly by a current shunted from the electrode leads, or by a transformer current, derived from the primary current through the main electric lead and electrode, or a shunt therefrom. This secondary current is used to energise an electro-magnetic device, comprising a construction such as is employed in a single-phase repulsion motor. A rheostat is also provided whereby a hand adjustment may be used in addition to the automatic adjustment of the current.—B. N.

Furnaces; Method of producing and controlling high temperatures in electric—J. J. Denton. London, Eng. Pat. 109,639, Aug. 21, 1916. (Appl. No. 11,844 of 1916.)

HIGH temperatures in an electric furnace are produced by forming an ionising path for the current by chemical agency, employing compounds which in a state of fusion or when blended with others set up free ions, and the temperature is afterwards controlled by additions to the furnace to an extent to suit the temperature required. Thus, caustic alkali mixed with sand may be sprinkled in a gully made in the resistor material, or may be used in the form of a cartridge placed on the resistor material between the electrodes, and moistened with water. Ions are thus produced for starting the conduction of the current. The temperature may be localised by adding to desired parts of the resistor, to suit the temperature required, further material, such as lime, which is adapted to produce an increased ionising path at a higher temperature, and therefore produces an increased flow of current.—B. N.

Furnace; Electric—D. R. Knapp, Assignor to The Eastern Steel Co., Pottsville, Pa. U.S. Pat. 1,240,460, Sept. 18, 1917. Date of appl. Feb. 19, 1916.

AN induction furnace is provided with a fixed base, and a supporting casting mounted on the base so that it may be revolved. A circular element is supported by a trunnion on the casting, and a crucible or trough is mounted on it. The

furnace is provided with means for heating the metal in the trough by induction, and it may be locked against rotation. An oscillating movement of the circumference may be given to the trough in its locked position, by varying the plane of the circular element, and when the furnace has been released it may be revolved to discharge the metal in any radial direction. A maximum cross-sectional area of metal at one part of the trough, and a minimum cross-sectional area at another part, may thus be produced, and the position of the maximum and minimum areas may be varied simultaneously.—B. N.

Electric furnace; Polyphase—J. L. Dixon, Detroit, Mich. U.S. Pat. 1,241,499, Oct. 2, 1917. Date of appl., June 26, 1917.

In a three-phase electrode furnace, the current flowing through one of the electrodes passes through a solenoid and is counterbalanced to a larger or smaller degree by an opposing smaller solenoid. By means of movable magnetic cores connected to a pivoted beam, the opposing magnetic flux is adjusted by the resultant of the currents flowing through the other electrodes, and at the same time the movable beam actuates the circuit controller of a motor which raises or lowers the first-mentioned electrode.—J. N. P.

Electric furnaces; Regulating apparatus for (automatic adjustment of electrodes in)—W. Sykes, Pittsburgh, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,241,574, Oct. 2, 1917. Date of appl., Apr. 12, 1912.

THE electrode is suspended by a cord passing over a pulley and round a conical drum connected to a motor. The electrode is counterbalanced by a weight attached to a cord wound, in the opposite direction, round a cylindrical portion of the drum and the variations in the weight of the electrode as it is consumed are compensated by the movement of the cord on the conical drum. The motor is operated by a current induced from the main circuit, and thus adjusts the height of the electrode above the furnace to maintain a definite constant strength of current in the arc.—J. N. P.

Electric-arc furnace [for nitrogen fixation], O. J. S. Platou, Assignor to Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. U.S. Pat. 1,241,655, Oct. 2, 1917. Date of appl., June 2, 1916.

In an arc furnace with a magnetically spread flame, the circular reaction vessel has the shape of a tall narrow rectangle in cross-section and is surrounded by a casing of approximately spherical shape. The windings of the magnet coils are arranged in the air space between the reaction chamber and the outer casing, and the magnet poles, which project a short distance into recesses in the walls of the inner chamber, are in metallic connection with the outer casing. By maintaining a slight negative pressure, air for the reaction is drawn into the inner air space through holes in the walls of the inner chamber from the air space between the casings.—J. N. P.

Insulation of condensers for telephone circuits, C. Cordes, Magdeburg, Germany. U.S. Pat. 1,241,926, Oct. 2, 1917. Date of appl., Dec. 17, 1910. Renewed Jan. 18, 1917.

A MATERIAL for impregnating telephone condensers which is solid, easily fusible, and of higher insulating capacity than paraffin, is prepared from castor oil by treatment with hydrogen in the presence of finely-divided catalytic metal at a raised temperature.—J. N. P.

Electrolytic apparatus, H. R. Hanley, Wintthrop, Cal., Assignor to Bully Hill Copper Mining and Smelting Co. U.S. Pat. 1,241,967, Oct. 2, 1917. Date of appl., June 5, 1916.

In an electrolytic cell with the anodes and cathodes in close proximity, use is made of a hollow anode having a number of openings in the lower part, through which air is delivered so as to brush away gas bubbles adhering to the cathode.—J. N. P.

[*Electrical contacts; Compositions of matter [for —] and processes of making same*. A. J. Liebmann, New York. Eng. Pat. 109,870, Nov. 2, 1916. (Appl. No. 15,692 of 1916.)

SEE U.S. Pat. 1,177,119 of 1916; this J., 1916, 608. Molybdenum, titanium, or the like may be used in place of tungsten, and the components are preferably mixed with a binder which can be subsequently volatilised. Mercury, introduced in the form of copper amalgam, may be used as binder.

Electrolysing apparatus, R. J. J. Mueller, and Universal Oxygen Co., Sheboygan, Wis., U.S.A. Eng. Pat. 110,036, Oct. 16, 1916. (Appl. No. 14,690 of 1916.)

XII.—FATS; OILS; WAXES.

Palm kernel oil; Methyl nonyl ketone from—A. H. Salway. Chem. Soc. Trans., 1917, 111, 407—410.

THE author has succeeded in isolating methyl nonyl ketone from the volatile matter removed from palm kernel oil by steam distillation in the deodorisation process. The crude material used, which had been obtained on a large scale, consisted of a semi-solid fatty mass holding water in a state of emulsion, and containing 30% of free fatty acids, 26% of neutral fat, 1.2% of neutral volatile oil, and 28.7% of water. The odour and taste of the original palm kernel oil are essentially caused by the volatile neutral oil and to a minor extent by the volatile fatty acids. The crude material was again distilled in a current of steam, the volatile oil dissolved in ether and shaken with sodium hydroxide solution to remove fatty acids, and methyl nonyl ketone isolated from the neutral volatile oil by means of its sodium bisulphite compound. In an experiment starting with palm-kernel oil, 1200 grms. of the oil yielded 1.4 grms. (0.12%) of neutral volatile oil containing 90% of methyl nonyl ketone. Coconut oil treated in the same way yielded 0.03% of neutral oil, of which only 30% could be converted into a semicarbazone (compare Haller and Lassieur, this J., 1910, 704, 1330).

Turkey-red oil products; Technical analysis of—A. Goldberg and E. Zipper. Chem.-Zeit., 1917, 41, 401—402.

THE composition of commercial products consisting of mixtures of Turkey-red oil with various fat-solvents (petroleum spirit, oil of turpentine, chlorinated hydrocarbons, etc.) may be ascertained with sufficient accuracy in most cases by distillation with steam, followed by fractional distillation of the volatile portion and determinations of specific gravity, chlorine content, etc., of the fractions. Turkey-red oil itself yields no volatile oily products on distillation with steam.

PATENTS.

Cement paint. K. S. Laurie, Allahabad, India. Eng. Pat. 109,951, May 22, 1917. (Appl. No. 7343 of 1917.)

A PAINT is obtained by adding "a liquid hydrocarbon of the petroleum series" to a mixture of Portland cement and linseed oil, no further grinding being required.—A. DE W.

Paint and process of making same. W. A. West, Elkhorn, Wis. U.S. Pat. 1,241,067, Sep. 25, 1917. Date of appl., Aug. 18, 1916.

A PERMANENT emulsion paint is made by mixing a paint oil with an immiscible diluent of different specific gravity, e.g., skim milk, the mixture being homogenised by forcing it under a pressure exceeding 500 lb. per sq. in. through a medium impermeable under lower pressure, then mixing with a "body material," pigment, and an additional diluent liquid.—A. DE W.

Phenol-aldehyde condensation products. A. W. C. van Voorhout, The Hague. Eng. Pat. 110,041, Oct. 30, 1916. (Appl. No. 15,465 of 1916.)

TRANSPARENT phenol-formaldehyde condensation products are produced by heating together equal weights of pure phenol or cresol and formaldehyde together with a small amount of a basic catalyst, e.g., potassium hydroxide, until all the solvent water and about one-half of the water set free by condensation are distilled off and strong foaming occurs, when heating is discontinued; 20% by volume of a neutral liquid other than water, such as strong methyl or ethyl alcohol, is then added to prevent development of excessive heat and to facilitate expulsion of remaining water. When one-half of the alcohol is distilled off, the mass is run out into moulds. The final stages of the reaction are carried out slowly in a current of air at temperatures gradually increasing from 60° C. to 120° C. or higher, at normal pressure, over a period of about 30 hours. For opaque condensation products, impure phenol or cresol may be used, and alcohol replaced by 1 to 4% of turpentine and 2 to 3% of glycerin, whilst the addition of vaseline facilitates removal of the product from the mould.—A. DE W.

Phenols and formaldehyde; Manufacture of insoluble condensation products from —. W. Reeser, Amsterdam, Holland. Eng. Pat. 10,055, July 9, 1915. Under Int. Conv., July 29, 1914.

PATENTS.

Vulcanising; Apparatus for —. Soc. pour la Production et la Vente des Articles en Caoutchouc "Bogaty", and J. A. Talalay, Moscow. Eng. Pat. 109,906, Dec. 30, 1916. (Appl. No. 18,673 of 1916.)

UNIFORMITY of temperature is maintained by a steady injection of air or other gas from a number of nozzles along the length of the lower part of the vulcanising apparatus; the gas first streams upwards over a series of vertical steam coils and is then directed downwards by a series of baffles; part of the gas then passes into the outer atmosphere and part enters on a new cycle around the previous path. The articles under treatment therefore receive part of the necessary heat direct from adjacent steam coils and part from the circulating gas which has been heated in the manner described.—D. F. T.

Vulcanisation of rubber and similar materials. Dunlop Rubber Co., Ltd., London, and D. F. Twiss, Sutton Coldfield. Eng. Pat. 110,059, Dec. 9, 1916. (Appl. No. 17,756 of 1916.)

THE process of vulcanisation is accelerated by the introduction into the rubber mixing of a caustic alkali, such as sodium hydroxide or potassium hydroxide, either mixed with a finely-divided mineral compound or dissolved in an organic compound such as glycerol.—D. F. T.

[Chewing] gum and process of making same. W. B. Pratt, Wellesley, Mass. U.S. Pat. 1,240,875, Sep. 25, 1917. Date of appl., Nov. 1, 1913. Renewed Feb. 28, 1917.

THE solid, coagulated gummy residuum of the latex of the "cow tree," in which the original starch has been converted into sugar, is suitable for use as chewing gum. It is plastic and non-adhesive in the presence of water at 98° F. (37° C.), and brittle at about 50° F. (10° C.).—A. DE W.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning process in jellies: Ultramicroscopic investigation of the — W. Moeller. *Kolloid Zeits.*, 1917, 20, 257—270. *J. Chem. Soc.*, 1917, 112, ii., 454.

THE formation of an insoluble salt by the interaction of an electrolyte in aqueous solution and a second electrolyte in the jelly is not an essential condition in the production of laminated structures. An aqueous solution of silver nitrate when left in contact with a gelatin jelly containing no added electrolyte, gives rise to the formation of alternating layers. This cannot be attributed to the presence of small quantities of chlorides and phosphates in the jelly, for the same result is obtained when pure gelatin is used. The laminated structure would indeed seem to be produced when any ionisable salt diffuses into a jelly. The same heterogeneous structure results when gelatin jellies are subjected to the action of tanning solutions. The author's view (see this J., 1917, 465) that gelatin consists of a fibrillated substance (α -gelatin), the spaces between the fibrils being filled by a structureless substance (β -gelatin), is made the basis of an explanation of the rhythmic effects which are the result of the diffusion processes which occur when jellies are brought into contact with solutions of salts.

XVI.—SOILS; FERTILISERS.

"Black alkali" (sodium carbonate) in calcareous soils; Formation of — J. F. Breazeale. *J. Agric. Res.*, 1917, 10, 541—590.

THE term "alkali" applied to soils is commonly employed in the United States to designate an accumulation of soluble salts in soil, which, in the case of sodium carbonate, causes the soil solution to be dark coloured. The case investigated by the author is the presence of sodium salts in a calcareous soil. A series of solutions of a sodium salt, in distilled water free from carbon dioxide, of graduated concentrations was prepared and put into bottles with calcium carbonate, and the bottles were tightly stoppered and shaken for several days. The solutions obtained were titrated for sodium carbonate, using phenol-

phthalein as indicator. A series of tests was made also in presence of carbon dioxide, and the solutions were titrated for sodium bicarbonate using methyl orange as indicator. The effect of the presence of soluble calcium salts in these reactions was studied. It was found that small amounts of calcium nitrate and chloride greatly impeded the formation of sodium carbonate from sodium nitrate, chloride, and sulphate and calcium carbonate, and that on increasing the amounts the reaction could be stopped. The presence of calcium sulphate impeded but did not stop the reaction. Similar results were obtained in presence of carbon dioxide, except that calcium sulphate had no inhibitory action when sodium sulphate was the sodium salt used. The experiments were repeated in the presence of soil, and it was found that sodium salts increased the solubility of calcium carbonate in the soil, and that the formation of sodium carbonate took place as before. The sodium carbonate formed decomposed the organic matter of the soil, and in this respect was more active than sodium bicarbonate. The organic matter was partly protected from this action by the presence of sodium chloride and sulphate. The author's conclusion is that the crusts and barren spots found in alkali soils are due to the formation of sodium carbonate by the action of sodium salts on calcium carbonate.—J. H. J.

Gypsum as a fertiliser. O. Nolte. *J. Landw.*, 1917, 65, 67—73. *J. Chem. Soc.*, 1917, 112, i., 624.

OWING to its ability to undergo hydrolytic decomposition into acid and base, gypsum influences the reaction of the soil especially by virtue of the constituent with the predominating reaction, that is, the sulphuric acid. Consequently, as far as possible, gypsum should not be used with acid and physiologically acid fertilisers, and in particular should never be applied to acid soils. On the other hand, it acts favourably in conjunction with physiologically basic salts, as it removes or weakens the basic reaction resulting from plant growth, and so assists in the retention of a loose texture by the soil. Gypsum may be employed with advantage when there is a shortage of such physiologically active fertilisers as potassium sulphate and chloride, superphosphate, and ammonium sulphate.

Boron: Effect of three annual applications of — on wheat. F. C. Cook and J. B. Wilson. *J. Agric. Res.*, 1917, 10, 591—597. (See also this J., 1915, 675; 1916, 319.)

HORSE manure containing sufficient borax to act as a fly larvicide was used to fertilise an experimental plot of land on which wheat was grown for three successive years. On another plot, colemanite was used as the source of boron, and there were also control plots of manured and unmanured land. The borax was applied at the rate of 154 lb. of boric acid per acre in the first year and at the rate of 38.5 lb. (i.e., an amount sufficient to destroy larvæ) in the following years. The colemanite, which is less effective than borax as a larvicide, was applied at the rate of 50.75 lb. of boric acid per acre. It was noticed that there was a yellowing of the young wheat after the heavy dose of borax in the first year, and that there was a reduced yield of grain of about 10% in the first two years, while colemanite had little effect. In the last year all yields were low. Only minute amounts of boron were absorbed by the wheat and were divided about equally between the straw and the grain. Soluble boron compounds could be detected in the soil nine months after the first heavy dose, but not after the other doses. The boron appears to be gradually converted into insoluble compounds, and there is no evidence of a cumulative action.—J. H. J.

Coal gas ; Action of — on plants. III. Action of coal gas, whilst passing through soil or water, on roots and leafy branches. C. Wehmer. Ber. Deuts. Botan. Ges., 1917, 35, 403—410. J. Chem. Soc., 1917, 112, i., 618—619. (See also this J., 1917, 1021, 1106.)

ANNUAL plants such as cress, grasses, and beans, were grown in culture solutions through which coal gas was slowly bubbled, or in pots so arranged that coal gas could be led into the soil from above or below ; and leafy shoots of the lime, elder, privet, illex, *Philadelphus*, and various conifers were kept under observation in culture solutions treated with the gas. Undiluted coal gas was found to be highly toxic for the roots of plants, but the constituents of the gas which dissolve in water are not so acutely dangerous. The effect on young cress, for example, is much more striking if the gas is led upwards through the soil than if it is just led into the top layers. The experiments on leafy shoots showed that the ill-effects of coal gas on the upper parts of a plant are not always conditioned by damage to the roots. The effects of the ascent of water charged with the gas into the shoots vary remarkably from part to part of the shoot and from plant to plant. With the exception of the yew, most conifers are highly resistant, but the usual effect is an early shedding of the leaves, the rind and buds remaining practically unhurt. An atmosphere containing 1% of hydrogen sulphide is fatal to the seed or seedlings of cress, but in the concentration 0.03%, that is, more than is commonly found in coal gas, this "poison" is distinctly beneficial to the germination of cress.

Sulphuric acid ; Effect of addition of — to the soil on the growth of the beet. K. Andrlík. Z. Zuckerind. Böhm., 1917, 41, 685—688. J. Chem. Soc., 1917, 112, i., 620.

INSTEAD of adding soluble nutrients to the soil, the author has tried the effect of applying cheap chemicals, like the mineral acids, to render more of the natural constituents of the soil available to the plant. He has compared the growth of the sugar beet on field plots sprinkled before seed-time with dilute sulphuric acid (2—4 kilos. per acre) and on untreated plots, and finds indications that the weights of root and leaves are less, but the quantity and quality of the sugar slightly greater on the treated soil.

Plants ; Action of — on organic substances. G. Ciamician and C. Ravenna. Gazz. Chim. Ital., 1917, 47, II., 109—129.

IN order to determine whether the facts previously recorded (this J., 1917, 559) could be attributed to enzymic action of the plants, a series of experiments was made in which spinach leaves, preserved from putrefaction by toluene, were kept in contact with various organic substances for a month, in a current of oxygen. The carbon dioxide evolved was measured by absorption in baryta water. Catechol and saligenin were decomposed to a considerable extent, whilst salicylic and benzoic acids were practically unchanged, but partially inhibited the enzymic action of the leaves. Pyridine and piperidine were unaltered, but nicotine showed some autoxidation after exposure to light. Substances showing the greatest decomposition were also most readily affected by potassium permanganate. The enzymes were not present in the expressed juices of the leaves, but were insoluble and adhered to the material. No definite relationship could be traced between the amounts of carbon dioxide liberated and the decomposition of particular substances. The experiments indicate that it is not possible to state definitely that the diminution in substances inoculated into plants is due to autoxidation.—C.A.M.

Plants ; Nutrition of green — by means of organic substances. C. Ravenna. Gazz. Chim. Ital., 1917, 47, II., 131—139.

MAIZE plants were cultivated in sterile solutions of nutrient salts containing from 1 to 10% of dextrose. The leaves of plants which had been exposed to light during the cultivation contained starch, even when no carbon dioxide had been present. The region of the solar spectrum which had the greatest influence on the formation of starch was that which had also the greatest influence on the chlorophyll function. Plants cultivated in the solutions in an atmosphere free from carbon dioxide and oxygen did not show any formation of starch, even in the light. The general conclusion drawn from the experiments is that dextrose absorbed by the roots is oxidised in the plant system to carbon dioxide, which the chlorophyll of the leaves converts into starch.

XVII.—SUGARS ; STARCHES ; GUMS.

Sugar refinery products ; Origin of the nitrogenous colouring matters in —. V. Staněk. Z. Zuckerind. Böhm., 1917, 41, 607—614. J. Chem. Soc., 1917, 112, i., 544. (Compare this J., 1917, 935, and Stoltzenberg, 1916, 1169.)

IT has been suggested that the nitrogenous colouring matters (including "fucosezinc acid") in molasses and desaccharification residues may owe their formation to the condensation of amino-acids with sugars during the refinery processes. Maillard (this J., 1912, 144 ; compare A. R. Ling, this J., 1908, 1033) has already shown that many free amino-acids react with the common sugars to form such products, and the author has now tested whether such a condensation can take place in more or less alkaline solutions. It is found that when solutions of invert-sugar or sucrose are heated in an autoclave at 105°—130°C. with sodium glutamate or aspartate or with asparagine, carbon dioxide is liberated, the solutions become acidic, and dark colouring matters are formed which are almost completely precipitated by lead acetate. The same colouring matters are obtained if precipitated chalk is added to overcome the acidity. Without the amino-acid, the colour of the solution is not so deep, and the colouring matter is completely soluble in alcohol. With the amino-acid, nitrogenous substances which do not dissolve in alcohol are produced as well. A fraction, which somewhat resembles fucosezinc acid in being a very dark brown powder, soluble only in alkalis, has been isolated. Asparagine and aspartic acid give rise to much more of this product than glutamic acid.

Molasses ; The nitrogenous colouring matters of —. (1) H. Friedrich. (2) V. Staněk. Z. Zuckerind. Böhm., 1917, 41, 614—618. J. Chem. Soc., 1917, 112, i., 544—515.

FRIEDRICH states that about 72% of the sucrose present can be precipitated in a pure white condition by mixing molasses with an equal quantity of cold glacial acetic acid. Most of this acid may be recovered in a concentration of 71% by distillation, when a dark brown, asphalt-like mass is left containing about 18% of ash (23.75% K). This residue may be worked up for betaine by trituration with about six times its bulk of methyl alcohol. The insoluble portion (27%) is a nitrogenous colouring matter containing about 3.4% of nitrogen, and yielding yellow derivatives on nitration. Friedrich agrees with Staněk (see

preceding abstract) as to the nature of the nitrogenous colouring matter, except that he regards the condensation of the amino-acids as taking place with caramel substances rather than with the sugars themselves. He therefore proposes the term "caramelazine substances."

Slaněk points out that the colouring matters which he has obtained by heating solutions of sugars and salts of amino-acids were formed at temperatures below that at which caramel is produced. He also suggests that Friedrich was dealing not only with the original colouring matters of molasses, but also with new ones produced during the distillation by the condensation of the invert-sugar and amino-acids under the influence of the acetic acid.

Sugar syrup; Manufacture of inverted—N. W. Taussig, New York. Eng. Pat. 103,989, Jan. 25, 1917. (Appl. No. 1293 of 1917.) Under Int. Conv., Feb. 7, 1916.

SEE U.S. Pat. 1,181,086 of 1916; this J., 1916, 648. A small quantity of an edible gum may be added to the sugar solution.

Ocotillo plant; Apparatus for treating—for extracting the gum therefrom. E. W. Snyder, Los Angeles, and J. D. Crawford, San Francisco, Cal. U.S. Pat. 1,240,891, Sep. 25, 1917. Date of appl., Dec. 16, 1916.

THE apparatus consists of a digester fitted internally with a container for the plant. The container is open at the top, and the sides and bottom are perforated, and means are provided for heating between the lower part of the digester and the bottom of the container. The gum solvent is introduced in the form of a spray at the top of the digester and is directed into the container by vertical baffle-plates fitted to the top of the digester. The baffles also ensure the return to the container of condensed liquid from a cooler arranged in the top of the digester between the baffles. The digester is fitted with an outlet for discharging the extract at the bottom.—A. DE W.

XVIII.—FERMENTATION INDUSTRIES.

Malting and brewing in Germany during the war. W. Windisch. Woch. Brau., 1917, 34, 1—2, 9—10, 17—20, 25—29, 33—35, 41—44, 49—52, 57—60, 65—68, 73—78, 81—83, 93—96, 101—105, 113—117, 121—125, 129—134.

WITHIN the first year of the war the brewing of thin beers became necessary owing to reduced malt supplies. These "war beers" surpassed expectation in respect of head-retention, fullness of flavour, and stability, and they will probably remain popular after the war. In the second year the brewing of thin beers was further complicated by the exceptionally poor malting quality of the 1915 barleys, these containing a large proportion, e.g., 20—40%, of corns which germ-

inated only to the "chitting" stage under malting conditions. Good results were attained with these malts nevertheless, by fine grinding, cold pre-mashing, and proteolytic digestion; high yields of extract were thus obtained and the beers were rich in soluble nitrogenous matters which enhanced their fullness of flavour and still more their head-retaining power. The special measures referred to have been advocated for some time by the author (this J., 1916, 1170; also Emslander, 1917, 156, and Lehmann, 1917, 515) as enabling imperfectly modified or short-grown malts to be satisfactorily employed in brewing, and he considers that the experience gained with the malts from 1915 barleys will lead to a preference for short-grown malts, which of course entail a much smaller malting loss than those germinated for the usual period. When the shortage of malt became serious the German Government permitted the use of sugars in brewing for top-fermentation beers, but there is now no sugar available for this purpose. Discussing the flavour of "war beers" the author emphasises the importance of "condition," which not only contributes to the stability of the beers but also masks slight defects of flavour. Alcohol is another very important factor in conferring fullness of flavour, and for this reason it is undesirable to restrict attenuation in order to retain extract in the finished beer, or to produce worts rich in dextrins at the expense of fermentable sugar, for dextrins do not contribute much to palate-fulness. The paper contains a long description of the advantages of the mash-filter in brewing, and in a final theoretical section the author sets out his views on the interaction of the salts of brewing waters with those derived from the malt, and also on the changes undergone by the salts and sulphur present in barley, during germination (see this J., 1917, 608).—J. H. L.

Beers; Preparation of thin—and substitutes during the war. K. Windisch. Woch. Brau., 1917, 34, 213—215, 224—227.

A CIRCULAR issued by the German Brauerbund, relating to the production of light beers, recommends thin mashing, with cold pre-mashing if necessary, plentiful hopping, unrestricted fermentation at not too low temperatures, with frequent and vigorous rousing, and fairly long storage under a moderate pressure with a view to complete attenuation and good condition. The author discusses these and other points, more particularly in relation to the brewing of very thin beers, e.g., of 3% original gravity. By mashing-in with a large amount of water, so as to produce a first wort, say of 8° Balling, the dissolution of extract is facilitated and sufficient water is left over for sparging. Cold pre-mashing and proteolytic digestion are strongly recommended (cp. W. Windisch, preceding abstract; also this J., 1916, 1170). Mashies should be held for some time, e.g., half an hour, at the lower conversion temperatures, 62°—67° C., to ensure the maximum production of fermentable sugars, the formation of large amounts of dextrins being inadvisable (cp. preceding abstract). Plentiful hopping is essential for stability, flavour, and retention of head, and the amount used should be limited only by what the beer will stand. The primary fermentation must be arrested whilst sufficient sugar remains to bring the beer into condition during storage. The great importance of a high content of gas for thin beers renders it desirable to prolong storage for at least 3 or 4 weeks, under a pressure, say, of 0.4 atm., and at a temperature of about 3°—4° C., not low enough to cripple the yeast present. The necessity for shortening the primary fermentation makes it difficult to produce enough yeast for pitching.

The author describes methods of meeting this difficulty, which consist in producing two worts of different gravities, using the denser one for the production of the pitching yeast and afterwards adding the weaker one as krausen or priming, or if a single 3% wort is produced the yeast may first be grown for a short time in a small quantity of strong wort before pitching (cp. Schönfeld and Goslich, following abstract). In conclusion the author makes some remarks on non-alcoholic beverages.—J. H. L.

Yeast; Growth and fermentation of — in thin worts. F. Schönfeld and C. Goslich. *Woch. Brau.*, 1917, 34, 205—206.

THE authors discuss their experience of the fermentation of thin worts at the brewery of the Versuchs- und Lehranstalt Berlin. In bottom-fermentations 0.5 litre (0.26 kilo.) of pressed yeast was used per hectolitre for 7% as for 11% worts. For 6% worts the amount was finally reduced to 0.33 litre to prevent too rapid fermentation; very satisfactory results were thus obtained with worts treated with 2 lb. of hops per cwt. of malt. The same quantity of yeast was used for 3% worts, smaller amounts being undesirable owing to danger of infection. In top-fermentations 0.33 litre of yeast was used for 6% worts, and if beer of 3% original gravity was required the 6% wort was diluted with hopped water after fermentation. With a ruling temperature of 5°–6° C. in the fermentation cellar, the pitching temperatures found most suitable were 10° C. for bottom-, and 15° C. for top-fermentations. In spite of a slight rise in temperature in the 6% worts, there occurred ultimately a fall of 3°–4° C. To promote yeast growth it was found desirable to rouse the worts and also to stimulate the yeast before pitching by mixing it with a small quantity of 10–12% wort for some hours, to enable it to absorb nutriment and commence budding. By these measures sufficient yeast for pitching was obtained even from the 3% worts, the reproduction being 1½ or 2-fold in these cases, and 3 or 4-fold in the 6% worts. The yeast from the 3% worts, however, required rather frequent renewal.—J. H. L.

Yeast; Extraction of different preparations of dried —. E. Buchner and S. Skraup. *Biochem. Zeits.*, 1917, 82, 107—133. *J. Chem. Soc.*, 1917, 112, i., 613.

FROM yeast treated with acetone, the zymase, pepsin, and endotryptase can only be extracted by water after grinding. This is not the case, however, with air-dried yeast prepared by Lebedev's process. From such preparations, the zymase, etc., are readily extracted by water, and previous grinding does not improve the extracts. The authors discuss in some detail the structure of the yeast and the theories put forward to explain the relationships between the enzymes and the protoplasm.

Fermentation processes; Action of toluene on —. E. Buchner and S. Skraup. *Biochem. Zeits.*, 1917, 82, 134—140. *J. Chem. Soc.*, 1917, 112, i., 613.

TOLUENE has practically no influence on the rate of fermentation by acetone preparations of yeast. This is not in accordance with the results of Euler and Kullberg (this J., 1911, 973). On repeating their experiments (at 31° C.) with Lebedev preparations or maceration juice made therefrom, it was found that toluene did inhibit fermentation, as these authors observed. The inhibition took place however, only in the earlier stages of the fermentation; in later stages this could not be

observed: in fact, after the first inhibition, the rate increased somewhat in the presence of toluene.

Invertase; Influence of glycerol on the activity of —. E. Bourquelot. *Comptes rend.*, 1917, 165, 567—569.

ATTEMPTS to effect a synthesis of sucrose by the action of invertase on dextrose and levulose dissolved in glycerol, gave negative results. Further experiments showed that glycerol affects the enzyme. For example, in 10% aqueous solutions it appreciably impairs, and in 50% solutions almost completely destroys the hydrolytic activity of the invertase.—J. H. L.

Bacillus paralacticus. F. Ducháček. *Biochem. Zeits.*, 1917, 82, 31—47. *J. Chem. Soc.*, 1917, 112, i., 612—613.

B. paralacticus was isolated from lactobacilline. It produces in milk 0.6—0.7% lactic acid, whereas *B. bulgaricus* produces under the same conditions 2.3—2.5%. If the bacillus acts in the presence of the neutralised medium (in the presence of calcium carbonate), 50% of the sugar can be fermented in four months. Under the same conditions, *B. bulgaricus* can cause fermentation of the whole of the sugar within ten to fourteen days. The reason of this difference is that the coagulum produced in the fermentation is sufficiently acid to inhibit the action of the former species of bacillus. The best medium for the growth of *B. paralacticus* is peptonised malt extract containing a suitable sugar. A further distinction between *B. bulgaricus* and *B. paralacticus* is that the latter produces *r*-lactic acid, whereas the former produces an inactive acid. About 4.6% of the acid produced is in both cases acetic acid.

Digesters [for boiling amylaceous materials under pressure]. H. Boulard, Paris. Eng. Pat. 110,015, Oct. 4, 1916. (Appl. No. 14,102 of 1916.)

DIGESTERS used for boiling amylaceous materials under pressure are connected together in pairs by means of a pipe fitted with a valve which, when opened, allows steam to pass from one digester to the other. The connecting pipe is fitted near the top of the digesters so that steam can pass from one to the other without carrying over any considerable amount of material with it. When the boiling is completed in one digester, the valve is opened and steam allowed to pass into the second digester containing a new charge of material. The valve is closed when the pressure of the steam in the first digester is just sufficient to expel the digested material.—J. H. P.

Acetone, alcohol, and yeast; Process for the preparation of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 291,683, Mar. 10, 1914.

THE wort is subjected to fermentation first with *Bac. macerans* and then with yeast. In this way not only are alcohol and acetone obtained but also a good crop of yeast.

Apparatus for impregnating liquids with carbonic acid or other gases. Eng. Pat. 109,958. See I.

XIXa.—FOODS.

Starch in preserved meats, etc.; Determination of —. Challet. Bull. Soc. Pharm. Bordeaux, 1917, No. 1. Ann. Chim. Analyt., 1917, 22, 206—209.

THE quantity of starch present is found from the cupric-reducing power of the material before and after hydrolysis. The hydrolysis is carried out by boiling 5 grms. of the sample for 1 hour under a reflux condenser with 50 c.c. of a solution consisting of hydrochloric acid (sp. gr. 1.25), 110 c.c., sodium chloride, 100 grms., and water, 400 c.c. Clarification is effected by means of basic lead acetate, phosphotungstic acid, or sodium metaphosphate; the cupric-reducing power is expressed in terms of dextrose, and the difference between the amounts of dextrose found before and after hydrolysis is multiplied by 0.9 to obtain the quantity of starch. If the preserved meat contains liver, the quantity of starch present can only be determined approximately; to allow for unchanged glycogen, the amount of reducing substances found before hydrolysis is multiplied by 2 before it is subtracted from the total reducing substances. Allowance must be made for lactose, if this sugar is present.

—W. P. S.

Starch; Determination of — in clover. T. von Fellenberg. Mitt. Lebensmittelunters. Hyg., 1917, 8, 55—56. J. Chem. Soc., 1917, 112, ii., 515—516.

THE author has recently described a direct method for the estimation of starch (this J., 1917, 935). In certain cases, particularly with ground clover, difficulties are experienced in the precipitation of the starch, due to the action of protective colloids; in such cases, the following modification of the process is advocated. The substance (1 gm.) is dissolved in 20 or 25 c.c. of calcium chloride solution (1:1); the solution is diluted to 100 c.c. and immediately filtered, since otherwise a larger amount of the disturbing substance is dissolved. Seventy-five c.c. of the filtrate is treated with a slight excess of N/50-iodine solution and agitated for five minutes. The residue is extracted with dilute calcium chloride solution (1 in 10; 30—40 c.c.). N/50-thiosulphate solution is added until it is decolorised, and the starch is again precipitated and centrifuged; the residue is treated with a few c.c. of dilute calcium chloride solution containing a few drops of iodine solution, collected in a Gooch crucible, and washed with calcium chloride solution containing iodine. The process is completed as described previously.

Chlorine; Volumetric determination of — in foods, etc., by the wet method without formation of ash. A. Weitzel. Arb. K. Gesundh. Amt., 1917, 50, 397—404. J. Chem. Soc., 1917, 112, ii., 501.

SMALL quantities of chlorine are readily lost in the customary estimation of this substance in the ash of organic substances. Two processes are therefore described which are available for foods, etc., and do not necessitate the preparation of an ash. According to the material, decomposition is effected with nitric acid or sodium hydroxide. The examination of meat or dog biscuit is effected as follows. Air-dried meat (2 grms.) or biscuit (5 grms.) is heated with nitric acid (sp. gr. 1.15, 20 c.c. or 50 c.c.) under a reflux condenser on a boiling-water-bath, with occasional shaking, for thirty minutes. Water (50 c.c. or 20 c.c.) is now added, and the mixture is heated over a gauze to gentle boiling for fifteen minutes. The cooled liquid is treated with 10 c.c. of silver nitrate solution (1 c.c. = 0.005 gm. NaCl), warmed for 15 mins. on the steam-bath, cooled, diluted with water to 100 c.c., and filtered. The excess of silver nitrate

is estimated in 50 c.c. of the filtrate by titration with ammonium thiocyanate in the presence of iron alum. In the examination of ling and salted fish roe, 2 to 5 grms. of the powdered, sieved, air-dried substance (according to the chlorine content) is heated on the steam-bath with occasional shaking during thirty minutes with potassium hydroxide solution (10%, 20—50 c.c.); after being cooled, the solution is diluted to 250 c.c. Twenty-five c.c. of this solution is mixed with nitric acid (sp. gr. 1.15, 20 c.c.) and standard silver nitrate (20 c.c.), and the mixture is heated under a reflux condenser to gentle ebullition until the colour becomes pale. The cold liquid is diluted to 100 c.c., filtered, and the chlorine estimated in 50 c.c. of the filtrate. The process yields accurate results, which are slightly higher than those obtained by the usual method, because, in the latter case, small amounts of alkali chlorides are lost by volatilisation.

Cocoa; Determination of the alkalinity of — and detection of added alkali. X. Rocques. Ann. Chim. Analyt., 1917, 22, 201—204.

THE total ash is determined on a quantity of the cocoa corresponding with 5 grms. of the dry, fat-free substance, and the soluble and insoluble portions of this ash are determined in the usual way by thorough extraction with boiling water; the alkalinity of the soluble ash is found by titration, using methyl orange as indicator and boiling the solution, the result being expressed in terms of K_2CO_3 on the dry, fat-free cocoa. The neutralised solution is then used for the determination of the P_2O_5 . According to French law, the alkalinity of the soluble ash must not exceed 2.75%, expressed as K_2CO_3 on the dry, fat-free substance; if this limit is exceeded, the article must be sold as "solubilised cocoa." With pure cocoa, the quantity of soluble ash is about one-half of the amount of insoluble ash; when 1.5% of added alkali (as K_2CO_3) is present the two quantities are equal, and with larger proportions of alkali the soluble ash exceeds the insoluble ash; the insoluble ash decreases slightly in quantity with increasing quantities of added alkali, due to a portion of the phosphates being rendered soluble. The soluble phosphoric acid shows a corresponding increase. The presence of added alkali, of course, increases the alkalinity of the soluble ash and also to a very slight extent that of the insoluble ash.—W. P. S.

Methyl alcohol in plants; Various modes of combination of —. Determination of pectin- and lignin-methyl alcohol in roots. T. von Fellenberg. Mitt. Lebensmittelunters. Hyg., 1917, 8, 1—29. J. Chem. Soc., 1917, 112, i., 616—617.

IN addition to pectin, the majority of plants contain other methoxy-compounds in which the methoxy-group is more firmly combined and is not eliminated by sodium hydroxide. In such cases, methyl ethers are obviously present. Since Zeisel's process is somewhat cumbersome and does not allow a distinction between the methyl groups present in ester or ether groups, the author has modified his previous process (this J., 1915, 574; 1916, 860). This also presents the advantage of only indicating methyl groups, whilst, by Zeisel's methods, other alkyl groups are also eliminated. The lignocelluloses, and also suberin, contain firmly-bound methyl alcohol. In accord with König and Rump, the author includes under the term "lignin" those non-volatile methoxy-compounds of plants which are insoluble in alcohol and ether and do not yield methyl alcohol when treated with sodium hydroxide, but do so with concentrated sulphuric acid. Since the methoxy-content of these substances is variable and

generally unknown, and the compounds can only be recognised by their methoxy-content, the author prefers to consider them as "lignin-methyl alcohol," and not as "lignin." The assumption of König and Rump (this J., 1915, 1203), that cellulose and lignin are only intimately associated and not chemically united in the crude fibres, is not justified by the evidence they adduce. In connection with the form of occurrence of methyl alcohol in plants, the author has examined pine wood, cork, normal and brown hay, roots and their adulterants, cacao and cacao shells. It is found that the pectin of wood is not identical with that of fruit, since it is insoluble in water and not dissolved when heated under pressure with organic acids. Cork contains several methoxylated acids and a certain proportion of lignin, the methyl alcohol of which constitutes about 25% of the total methyl alcohol. In the fermentation of brown hay, methyl alcohol is eliminated from the pectin and partly oxidised to formic acid; simultaneously, an increase occurs in the lignin-methyl alcohol.

For the estimation of total methyl alcohol, the finely ground sample, freed from fat if necessary (0.2–0.5 grm.), is heated to gentle ebullition for ten minutes with sulphuric acid (72%, 15 c.c.). After cooling water (25 c.c.) is added, and the mixture is distilled until 25 c.c. has been collected. The distillate is made alkaline with sodium hydroxide, and again distilled until 16.2 c.c. has passed over. With substances of low methoxyl content, two further distillations are performed, in which 10 c.c. and 6 c.c. respectively are collected. The final distillate is weighed and colorimetrically investigated, as previously described. The lignin-methyl alcohol is deduced from the differences between the values for the total and pectin-methyl alcohol. When very small quantities of lignin are present, it is advisable to estimate both forms in the same sample; the distillation residue obtained after estimation of the pectin is collected, washed with hot water, alcohol, and ether, dried, and distilled with sulphuric acid.

Bread: Manufacture of a concentrated — C. A. Heudebert, Nanterre, France. Eng. Pat. 107,192, Sept. 18, 1916. (Appl. No. 13,230, 1916.) Under Int. Conv., June 15, 1916.

FIVE hundred grms. of "grain" yeast is mixed with 32 litres of warm water, 30 kilos. of flour is incorporated with the liquid and, after 1 hour, the mixture is poured into a kneading machine together with 70 kilos. of flour; 1 kilo. of salt dissolved in 3 litres of water is also added. The dough is milled, rolled into strips, and cut into square cakes which are kept in the dark in a slightly moist atmosphere at 30° to 40° C. for about 1 hour. The cakes are then baked at about 210° C. for 40 mins., and allowed to cool slowly in covered boxes for 24 hours. The product is friable and has a regular, porous texture.—W. P. S.

Organic phosphorus compound contained in vegetable foodstuffs: Manufacture of the assimilable — O. Imray, London. From Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 109,519, Oct. 24, 1916. (Appl. No. 15,146 of 1916.)

FOUR hundred and fifty kilos. of paste containing 30% of the tetrabasic calcium salt of the organic phospho-compound obtained as described in Eng. Pat. 23,692 of 1903 (this J., 1904, 126) is dissolved in 60 kilos. of pure concentrated (30%)

hydrochloric acid, 0.5 kilo. of animal charcoal is added, and the mixture stirred for 1 hour; it is then filtered and the calcium which is not combined with the phospho-compound is precipitated by adding to the filtrate 15 to 18 kilos. of oxalic acid dissolved in water. The calcium oxalate is separated by filtration and the filtrate is mixed with 1200 litres of 95% alcohol; the dibasic salt of the organic phospho-compound thus precipitated is collected, washed, and dried. It forms a white, tasteless powder.—W. P. S.

Milk sterilising apparatus. F. H. Rogers, London, and W. T. Fremlin, Maidstone. Eng. Pat. 109,638, Aug. 18, 1916. (Appl. No. 11,750 of 1916.)

IN apparatus of the type in which a central steam-chest is surrounded by a series of external annular steam-chests forming passages for the flow of the milk, the cover for the various sections is so constructed that clamping it in position completes the connections between the milk sections and also between the steam sections. The walls of each of the steam sections are secured at top and bottom to annular rings which engage concentric grooves in the cover and base, rubber rings being used to ensure tight joints. Nipples project upwards from each steam section into ports within the cover so as to place the sections in communication with one another when the cover is in position. The rings closing the lower ends of the intermediate steam sections have feet or lugs which rest on the base and provide passages for the circulation of the milk.—W. P. S.

Casein: Method of drying — W. M. Brownell, Brooklyn, N.Y., Assignor to A. N. Hood and J. T. Nightingale, Boston. U.S. Pat. 1,240,816, Sep. 25, 1917. Date of appl., May 5, 1916. Renewed Feb. 20, 1917.

CASEIN is heated until it forms a plastic adhesive mass, and is then passed under pressure through a heated chamber and out into the open air.

Means for desiccating liquors containing matter in solution or suspension [e.g., milk and the like]. Eng. Pat. 109,471. See 1.

XIXB.—WATER PURIFICATION; SANITATION.

Chloride of lime; Interaction of — with the normal constituents of natural waters and sewage. G. W. Heise. Philippine J. Sci., 1917, 12, A, 17–34.

THE author has studied the rate of decomposition of chloride of lime in water, sewage, and solutions of organic substances. Available chlorine was estimated by taking samples, as required, and titrating with standard sodium thiosulphate solution in the presence of phosphoric acid, potassium iodide, and starch solution. It was found that in the dark, at ordinary temperatures, the reactions proceed with almost constant velocity for periods of 30 mins. to 1 hour, after which they proceed very slowly. In the light the rate of decomposition is greatly accelerated. The amount of chlorine consumed is usually proportional to the concentration in which it is added: on the other hand, the chlorine consumption is not necessarily proportional to the concentration of organic matter. In the control of the disinfection of water or sewage by hypochlorite, bacteriological tests should supplement determinations of chlorine consumption. These latter should be carried out as nearly as possible under the conditions of temperature, illumination, and concentration that obtain in practice.—L. A. C.

Manufacture of alkaline peroxide. Eng. Pat. 101,709. See VII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids of ipecacuanha. Part II. F. L. Pyman. Chem. Soc. Trans., 1917, 111, 419—446. (See this J., 1914, 764.)

THE non-phenolic ether-soluble alkaloids of ipecacuanha were converted into the hydrobromides and crystallised from water. After separation of the emetine hydrobromide, the mother liquor was mixed with sodium hydroxide solution and extracted with chloroform. The base recovered from the chloroform solution was dissolved in alcohol and mixed with half its weight of hydrated oxalic acid dissolved in hot alcohol, when a deposit of a crystalline hydrogen oxalate was obtained. This salt was obtained from all the commercial varieties of ipecacuanha examined, namely Matto Grosso, Minas, Cartagena, and Johore, the yields ranging from 0.03 to 0.06% of the weight of the bark. The crude salt consists chiefly of the hydrogen oxalate of a new base which was found to be the O-methyl ether of psychotrine, together with a smaller quantity of the hydrogen oxalate of another new base, which has been named emetamine. The two alkaloids were separated by fractional extraction with dilute acid from chloroform solution, when the more basic methylpsychotrine was removed first. It was purified by crystallisation of the sulphate, which forms large colourless prisms containing 7H₂O, melting, with effervescence, at 247° C. (corr.) after becoming yellow at about 220° C. Methylpsychotrine is much more readily soluble in dry ether than in wet ether, probably combining with water to form a hydrate as does psychotrine. It is dextro-rotatory both as free base ($[\alpha]_D = +43.9^\circ$ in commercial absolute alcohol) and in the form of salts. Methylpsychotrine is formed in small quantity, together with a substance similar in properties to rubremetine (Carr and Pyman, this J., 1914, 764), by the oxidation of emetine with two atomic proportions of iodine. Karrer's dehydroemetine iodide, obtained by the oxidation of emetine with a larger proportion of iodine (this J., 1916, 1177) is shown to be identical with rubremetine hydroiodide. When reduced with sodium and alcohol, methylpsychotrine yields a mixture containing emetine and an isomeride of emetine (isolated as benzoylisometine, C₂₅H₃₅O₄N₂.CO.C₆H₅, m.pt. 207°—208° corr.), together with phenolic bases and a new crystalline (diacidic) base, C₂₅H₃₅O₃N₂ or C₂₅H₃₃O₃N₂, m.pt. 128° C., which is non-phenolic and contains three methoxyl groups. When heated with benzoic anhydride, methylpsychotrine yields a colourless, monobasic N-benzoyl derivative; hence it and consequently psychotrine also, contains an imino-group, and the opinion previously expressed that psychotrine is a tertiary base is incorrect. The formation of cephaeline and isocephaeline by reduction of psychotrine, and of emetine and isometine by reduction of methylpsychotrine is thus due to the reduction of a C:C and not of a C:N linking.

Emetamine was purified by crystallisation of its hydrobromide, and was obtained in colourless needles, m.pt. 155°—156° C. It has the formula, C₂₅H₃₅O₄N₂ or C₂₅H₃₃O₄N₂, contains four methoxyl groups but no N-methyl group, is non-phenolic, and a diacidic base. It does not yield a benzoyl derivative when heated with benzoic anhydride. It is dextro-rotatory ($[\alpha]_D = +12.3^\circ$

in absolute alcohol), but its salts are laevo-rotatory. No other alkaloids besides methylpsychotrine and emetamine appear to be present in the original crude hydrogen oxalate, and it has been calculated from the rotatory powers of the crude salt and of the hydrogen oxalates of the pure alkaloids that the different commercial varieties of ipecacuanha contain from 0.015 to 0.033% of methylpsychotrine and 0.002 to 0.006% of emetamine. The hydrobromides of both alkaloids are precipitated by sodium bromide, and they are probably constituents of Hesse's hydroipecamine hydrobromide (this J., 1914, 601). Further experiments on N-methylemetine and its salts and the methine derived from its methiodide are also described.

Emetine has proved of value and has been largely employed for the treatment of amoebic dysentery in the Expeditionary Forces operating in hot climates. The other alkaloids of ipecacuanha and their derivatives and also derivatives of emetine have been investigated with a view to obtain, if possible, a substance in which the relative toxicity to amoeba and man is greater than in the case of emetine, but none of the compounds examined appear to have important advantages over emetine therapeutically (see also following abstract).

Ipecacuanha alkaloids and some synthetic derivatives of cephaeline; Pharmacological studies of the toxicity of —. A. L. Walters and E. W. Koch. J. Pharm. Expt. Ther., 1917, 10, 73—81. J. Chem. Soc., 1917, 112, i., 612. (Compare Karrer, this J., 1916, 1177.)

THE authors have measured the relative toxicity of the methyl, ethyl, propyl, isopropyl, butyl, isobutyl, *tert*-butyl, amyl, isoamyl, and allyl ethers of cephaeline. The substitution of the methyl group in emetine (cephaeline methyl ether) by radicals of the higher homologous alcohols markedly decreases the toxicity for rats, guinea-pigs, and rabbits. The isoamyl ether is the least toxic of the series, having about one-fifth the toxicity of emetine when given subcutaneously. Emetine is not a very toxic alkaloid when given in a single dose, but is dangerous when given repeatedly in small doses over a considerable period of time.

Sparteine; Microchemical reactions of —. O. Tunnmann. Apoth.-Zeit., 1917, 32, 100—103. J. Chem. Soc., 1917, 112, ii., 518—519.

A 1—2% SOLUTION of sparteine when treated with a drop of dilute chromic acid gives immediately a pale yellow precipitate consisting of small droplets; after a short time these change into a mass of colourless needles which speedily become straw-yellow; single well-defined prisms are also formed. 0.1 mgrm. of the alkaloid yields after some time crystals united to form lattices, which slowly become transformed into prisms. The limit of sensitiveness is 50 µgrm. With concentrated zinc chloride solution (1:1), a white precipitate is formed consisting of aggregates of short rods. In presence of a trace of hydrochloric acid, the white turbidity does not appear, but, after fifteen minutes, individual prismatic crystals are formed which show marked polarisation colours and extinction parallel to the long axis; limit of sensitiveness, 0.4—0.3 µgrm. When the alkaloid is warmed with copper chloride solution (4%) and hydrochloric acid, long, lemon-yellow prisms are gradually formed. The excess of copper chloride (which is usually only deposited when the solution is completely evaporated) appears as colourless or pale green needles or prisms. The reaction is not very sensitive. With mercuric chloride and hydrochloric acid, a white precipitate is formed, which is converted

into rhombic prisms. With small amounts of alkaloid, the precipitate does not appear, but after twenty to thirty minutes, individual prisms are formed. These are insoluble in alcohol and glycerol; the limit of sensitiveness is 30–40 μ gm. The reaction with zinc chloriodide solution has been described previously (this J., 1917, 941). Hydriodic acid gives a dark brown to black precipitate; under the microscope, long, blackish-brown prisms or brown or red aggregates appear after some hours. The crystals are readily soluble in alcohol and attacked by glycerol. Limit of sensitiveness, 5–3 μ gm. Potassium iodide gives a brown precipitate, which is soon converted into brownish-black nodules, from which paler, prismatic needles are formed; limit of sensitiveness, about 5 μ gm. Potassium cadmium bromide [cadmium bromide (1 gm.), potassium bromide (2 grms.), water (7 grms.)] yields colourless, flat prisms, which are converted into dendritic aggregates. In addition, rhombic platelets and brown globules are formed. The crystal forms are very diverse. The crystals are insoluble in glycerol. Limit of sensitiveness, 8–5 μ gm.

Geneserine: Constitution of —. Transformation of eserine into geneserine. Alkaloids of the Calabar bean. VI. M. Polonovski. Bull. Soc. Chim., 1917, 21, 191–200. (See also this J., 1915, 920, 1070; 1916, 273).

GENESERINE is regarded as the amine-oxide derivative of eserine produced by the attachment of an oxygen atom at the amino-group of the latter substance; the behaviour of geneserine with sulphur dioxide, and its oxidising action towards hydriodic acid and methyl iodide, are in accord with the properties of the amine-oxides, and the liberation of silver from neutral silver nitrate may be regarded as a process of "mutual reduction" analogous to the reaction of hydrogen peroxide with permanganic acid. This view of the constitution of geneserine was confirmed by oxidation experiments, potassium permanganate or dilute nitric acid giving rise to methylamine as the only isolated product from eseroline, whereas in aqueous-alcoholic solution hydrogen peroxide actually effected the conversion of eserine into geneserine. Similarly eserethol in acetone solution was oxidised by hydrogen peroxide with formation of geneserethol, but the conversion of eseroline into geneseroline could not be effected. The difference between the constitution of eserine and geneserine is therefore to be represented by the two formulæ $\text{CH}_5\text{N}:\text{C}_{12}\text{H}_{14}\text{N}\cdot\text{O}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_3$ and $\text{O}:\text{N}(\text{CH}_3):\text{C}_{12}\text{H}_{14}\text{N}\cdot\text{O}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_3$.—D. F. T.

Yohimbine and quebrachine. E. Filippi. Arch. Pharmacol. Experim., 1917, 23, 107–128, 129–140. J. Chem. Soc., 1917, 112, i., 582.

FROM purely chemical evidence, Fournneau and Page (this J., 1914, 373) have come to the conclusion that yohimbine and quebrachine are identical (compare Spiegel, this J., 1916, 327). The author has carried out a careful pharmacological comparison of the two alkaloids, from which he concludes that although they are similar in many respects, yet in others they show such marked differences that they cannot be considered as identical, although belonging to the same pharmacological group. The chemical similarity of the two alkaloids with each other and with strychnine is further shown by the occurrence of Vitali's reaction.

Digitalis plants: Development of the typical glucosides of the leaf in germinating and growing —. W. Straub. Biochem. Zeits., 1917, 82, 48–59. J. Chem. Soc., 1917, 112, i., 615–616.

THE amount of the glucosides in different stages

of the growth of the plant was estimated by a pharmacological method (by ascertaining the number of lethal doses for a frog in different fractions). The glucosides in question are *digitalinum verum* and digitalein, which are soluble in water, and both of which are found in the seeds, and digitoxin, which is insoluble in water, but soluble in chloroform, and "gltalin," which is soluble in chloroform and cold water, which are found in the leaves (see also this J., 1917, 731). Digitalein also occurs in the leaves. As a result of pharmacological tests of the fractions obtained from plants in various stages of the growth, a very approximate quantitative estimation of these alkaloids could be made. It was found that the glucosides of the seeds are not reserve material, but disappear during germination, and are stored in the leaves, in which organs they do not increase further in quantity. The glucosides proper of the leaves make their first appearance in the earliest foliage leaves and continue to increase in quantity until they form 1% of the dried matter.

Pangium edule and Hydnocarpus alcala; Investigation of the seeds of —. H. C. Brill. Philippine J. Sci., 1917, 12, A, 37–46.

FROM the seeds of the *Pangium edule* the authors obtained the glucoside, gynocardin, and an oil, and from the leaves, the enzyme gynocardase. Gynocardin was obtained as golden yellow crystals, melting at 160° C., by recrystallising from hot water the alcoholic or hot water extract of the dried seeds. Repeated washing of the extract with ether or acetone was necessary in order to remove all traces of oil, otherwise the substance would not crystallise. This glucoside is characterised by its marked stability in the presence of hydrolysing agents as compared with other members of the same class, e.g., amygdalin. The oil contains palmitic and oleic acids and a small quantity of an optically active acid. From the expressed juice of the leaves the enzyme, gynocardase, was precipitated by the addition of alcohol. It was found to belong to the class of β -enzymes typified by emulsin. No cyanogenetic glucoside was discovered in the seeds of the *Hydnocarpus alcala*. Over 90% of chaulmoogric acid was present in the free acids of the oil expressed from these seeds.—L. A. C.

Amines: Transformation of secondary and tertiary — into nitriles. A. Mailhe and F. de Godon. Comptes rend., 1917, 165, 557–559.

VAPOURS of di-isoamylamine, b.pt. 187° C., passed over finely-divided nickel at 320°–330° C., yielded some permanent gas consisting of 78–80% of hydrogen and 20–22% of olefines, and a liquid product which on fractional distillation gave first some isoamylene at 35°–40° C., then a 60% fraction between 120° and 140° C., and afterwards unaltered di-isoamylamine, leaving a residue, b.pt. 200°–245° C., containing tri-isoamylamine. From the fraction distilling between 120° and 140° C., isoamyl nitrile (isobutyl cyanide), b.pt. 127°–129° C., was obtained. The reactions may be represented thus:—

Part of the isoamylene was decomposed into carbon and hydrogen by contact with the nickel. There was no evidence of the intermediate formation of primary amine. Vapours of tri-isoamylamine, b.pt. 235° C., passed over nickel at 360°–370° C., gave some permanent gas and a liquid containing isoamyl nitrile and unaltered tri-isoamylamine.—J. H. L.

Pine oil; "Oyster Bay" ——. P. Singh. *Perfum. and Essent. Oil Rec.*, 1917, 8, 304.

THE "Oyster Bay pine," *Frenela rhomboidea*, was introduced from Australia between 1885 and 1891, into the Nilgiri region (India) where it now covers about 130 acres. In experiments at the Forest Research Institute, Dehra Dun, it was found that about a ton of the green leaves, containing 43% of moisture, yielded (in November) 13.5 oz. of oil on distillation with steam at 40–60 lb. pressure. This oil gave satisfactory results as a soap perfume, in a Bombay factory. Its composition appears to be similar to that of the oil from the Australian *Frenela*, which is said to contain *l*-pinene, limonene, and dipentene, with geranyl acetate as chief ester constituent. The characters of the Nilgiri oil were:—Sp.gr. at 16° C., 0.871; $[\alpha]_D^{20} = -27.6$; n_D^{20} 1.4695 at 18°; ester value, 51; saponif. value before acetylation, 52.3, after acetylation, 59.8; free alcohols (as geraniol), 2.1%; total alcohols, 17.3%; esters (as geranyl acetate), 17.8%; solubility, in 90% alcohol, 0.75 part; 1 part dissolves in 21.5 parts of 80% alcohol.—J. H. L.

Citronellals; Two isomeric ——. H. J. Prins. *Chem. Weekblad*, 1917, 14, 692–695. *J. Chem. Soc.*, 1917, 112, i, 538.

By repeated fractionation, two isomerides have been isolated from citronellal. The first has b.pt. 203°–204° C., sp.gr. at 14° C. 0.8880, and forms a semicarbazone, m.pt. 85°–86° C. The second has b.pt. 198°–200° C., sp. gr. at 14° C. 0.8745, and gives a semicarbazone, m.pt. 82.5°–83° C. It is suggested that the first has the formula $\text{CH}_2\text{C}(\text{CH}_3)\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{CHO}$, and the second the formula

Zinc phenolsulphonate; Volumetric determination of ——. G. Adanti. *Boll. Chim. Farm.*, 1917, 56, 317–318. *J. Chem. Soc.*, 1917, 112, ii, 517.

IN the presence of bromine and an acid, zinc phenolsulphonate reacts in accordance with the following equations: $(\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3)_2\text{Zn}\cdot 7\text{H}_2\text{O} + 11\cdot\text{SO}_4 = \text{ZnSO}_4\cdot 7\text{H}_2\text{O} + 2\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{H}$ and $2\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{H} + 12\text{Br} \rightarrow 2\text{C}_6\text{H}_4\cdot\text{Br}_2\cdot\text{OH} + 6\text{HBr}$. Exactly 0.5 gram. of the crystallised zinc phenolsulphonate is dissolved in water and the solution made up to 500 c.c. In a flask holding about 300 c.c. and fitted with a ground stopper, 50 c.c. of this solution is mixed with 50 c.c. of 0.6% potassium bromide solution and 50 c.c. of 0.1671% potassium bromate solution, 5 c.c. of concentrated sulphuric acid being then added, and the flask again shaken and left closed in a dark place at about 25° C. for three hours. Ten c.c. of 10% potassium iodide solution, recently prepared, is next added, and, after the lapse of an hour, the iodine liberated is determined by titration with *N*/10 sodium thiosulphate. The number of c.c. of the thiosulphate used is subtracted from that required in a blank test with the 50 c.c. of bromide and 50 c.c. of bromate alone; the remainder, multiplied by 0.00447, gives the weight in grams of crystallised zinc phenolsulphonate in the 50 c.c. of solution taken.

Mercuric oxycyanide; Volumetric determination of ——. A. Tagliavini. *Boll. Chim. Farm.*, 1917, 56, 297–299. *J. Chem. Soc.*, 1917, 112, ii, 510.

MERCURIC oxycyanide, used as a disinfectant, particularly for the hands, may be analysed as follows:—A weighed quantity of 0.3–0.4 gm. of the salt is dissolved in 50 c.c. of cold water, and

the liquid, after treatment with 1 gm. of sodium chloride and a drop of 0.2% methyl orange solution, is titrated with *N*/10-hydrochloric acid until it turns red. After the volume of acid required is read, 2 grms. of potassium iodide is added to the solution, and the yellow liquid thus obtained is again titrated with *N*/10-hydrochloric acid as before. From the two volumes of acid required, the percentages of oxycyanide and cyanide in the salt may be calculated, the reactions proceeding according to the equations: (1) $\text{HgO}\cdot\text{Hg}(\text{CN})_2 + 2\text{HCl} = \text{HgCl}_2 + \text{Hg}(\text{CN})_2 + \text{H}_2\text{O}$, and (2) $\text{Hg}(\text{CN})_2 + 4\text{KI} + 2\text{HCl} = \text{HgK}_2\text{I}_4 + 2\text{KCl} + 2\text{HCN}$.

Mercury; Determination of — in galenical preparations. H. Wastenson. *Pharm. Post.*, 1917, 50, 125–126. *J. Chem. Soc.*, 1917, 112, ii, 509.

THE method of destroying organic matter previously employed in analysing protein preparations containing silver (this *J.*, 1916, 1271) is applied to the determination of mercury in galenical preparations. The substance (0.3–0.5 gm.) is heated with concentrated sulphuric acid (10 c.c.) and nitric acid (sp.gr. 1.4, 3 c.c.) until reddish-yellow vapours are not further evolved, the liquid has become clear and colourless, and the flask filled with sulphuric acid fumes. If the vapours still smell of sulphur dioxide, treatment with nitric acid (3 c.c.) is repeated. After being cooled, water (25 c.c.) is added, which is removed by evaporation. The cold solution is treated with water (15 c.c.) and potassium permanganate solution until a permanent pink coloration is produced: the latter is discharged with ferrous sulphate, the solution diluted with water (75 c.c.), and titrated with *N*/10-ammonium thiocyanate solution in the presence of ferric alum. The method is suitable for organic and inorganic preparations of the oxides of mercury, but not for such as contain the haloids. It can also be used for estimating mercury in plasters and pills, and in ointments provided that they are tolerably free from paraffin.

Methyl nonyl ketone from palm-kernel oil. Salway. See XII.

Action of plants on organic substances. Ciamicran and Ravenna. See XVI.

PATENTS.

[Acetaldehyde, etc.] *Products of condensation and oxidation from acetylene*; Manufacture of —. Chem. Fabr. Rhénania, B. K. Stuer, Aachen, and W. Grob, Stolberg, Germany. Eng. Pat. 109,983, July 17, 1916. (Appl. No. 10,042 of 1916.)

ACETYLENE alone or mixed with neutral gases, ammonia, hydrogen sulphide, or steam, is passed over contact substances, e.g., metallic oxides, at a high temperature. The presence of an oxidising agent or of compounds of alkalis, alkaline earths, or of magnesium is advantageous. Suitable temperatures are between 300° and 400° C., or, in presence of large amounts of steam, 400° to 500° C., at the ordinary or increased pressure. Acetaldehyde is the main product on passing a mixture of 1 part of acetylene and 4 parts of steam over bog iron ore at 400°–420° C. A 50% yield of acetonitrile mixed with bases containing nitrogen results on passing acetylene and ammonia in equal proportions over bauxite at 350°–380° C. Almost pure thiophen is prepared by passing a mixture of 2 parts of acetylene to 1 part of hydrogen sulphide over specially treated bauxite at 320° C.—F. W. A.

Urea ; Process of producing — J. E. Bucher, Coventry, Assignor to Nitrogen Products Co., Providence, R.I. U.S. Pats. (A) 1,211,919 and (B) 1,211,920, Oct. 2, 1917. Dates of appl. (A) July 3, 1914, (B) Oct. 21, 1915.

(A) AN alkali cyanate is treated with an ammonium salt of carbonic acid, to form ammonium cyanate and alkali bicarbonate. The ammonium cyanate is converted into urea, which is concentrated by adding solid alkali cyanate, and then separated by varying the temperature so as to utilise the differing rates of change of solubility of the urea and of the by-products of the reaction. Urea may also be separated from the alkali bicarbonate by adding alkali to form the normal carbonate, crystallising the urea, and then introducing carbon dioxide to remove a considerable part of the remaining alkali as bicarbonate. (B) The process described in (A) is modified by passing carbon dioxide into an ammoniacal solution of a metallic cyanate, so as to produce ammonium cyanate and a precipitate of metallic bicarbonate. Part of the ammonia required is derived from the decomposition of the cyanate in solution. After the ammonium cyanate has been converted into urea, the latter may be separated from the by-products by distilling off the water while passing in carbon dioxide to prevent conversion of the bicarbonate into carbonate.—F. Sp.

Manufacture of the assimilable organic phosphorus compound contained in vegetable foodstuffs. Eng. Pat. 109,519. See XIXA.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Colour photographs ; Taking and exhibiting of — A. H. Walker, London. From Hess-Ives Corporation, Philadelphia, U.S.A. Eng. Pat. 110,059, Feb. 8, 1917. (Appl. No. 1936 of 1917.)

IN colour photography, either in a camera or in a projection apparatus, in which a transparent reflector is used to separate the incident light into colour components or to combine coloured lights, a larger total amount of available light is obtained by coating the front surface of the mirror with a dichroic substance. A surface of Eosine, for instance, reflects about 59% of the incident green light and transmits about 50% of the incident red light, whereas a half-silvered glass, having no dichroic qualities, reflects 50% of the green light but transmits only 50% of the red light. A thin deposit of gold is more durable than Eosine but not so effective; it transmits more than 50% of the green and reflects more than 50% of the red. —B. V. S.

XXII.—EXPLOSIVES ; MATCHES.

Ammunition ; Investigation of defective small-arms — at Washington. Met. and Chem. Eng., 1917, 17, 375.

DEFECTS in small-arms cartridges from the Frankford Arsenal, Philadelphia, have been found to be due to the use of inferior mixtures in the composition of the primers, to the method of testing the various batches of cartridges at the Arsenal, according to which the results obtained varied from day to day with the same batch of ammunition, and to the exposure of the cartridges during active service to dampness and more vigorous climatic conditions than were covered by the specifications under which the ammunition was manufactured. Free sulphur when used in a primer composition has been found to give a deleterious compound with potassium bromate, which is present in the inferior grades of potas-

sium chlorate now being used; the defect thus caused would not appear in newly-finished ammunition. The use of mercury fulminate in place of sulphur has been recommended but not yet adopted. The inferior quality of the antimony sulphide and copper used has also contributed to failures.—J. N. P.

Nitrogen in explosives ; Determination of — B. Oddo. Gazz. Chim. Ital., 1917, 47, 11., 145—158.

A WEIGHED quantity of the substance is placed in the flask A, with a little sulphuric acid as solvent, and the tube, D, containing mercury in excess of the weight of sulphuric acid used, is introduced. The flask is then closed by the cork, through which passes the tube, B, and the bulb tube, C, in the base of which is a little sulphuric acid, and dry carbon dioxide is aspirated through the apparatus until all air is expelled (40 to 45 mins.). The openings of the tubes, B and C, are then closed and the apparatus weighed, the tube, C, opened,

and the mercury in the tube, D, made to fall into the acid in the flask. The apparatus is shaken with a circular motion and gently heated until the bubbles of nitric oxide pass regularly through the acid in C. When all gas has been evolved a current of dry carbon dioxide is again passed through the apparatus, which is then closed and weighed again. The loss in weight gives the amount of nitric oxide, which is calculated into nitrogen. Several of these flasks may be connected with the carbon dioxide apparatus for simultaneous determinations.—C. A. M.

XXIII.—ANALYSIS.

Electro-analysis apparatus. J. L. Jones. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 6 pages.

THE electrodes are stationary and consist of pieces of platinum gauze of 40 meshes per linear inch; the larger one, ordinarily arranged as cathode, weighs about 30 grms. and the smaller one 16 grms. Stirring of the electrolyte is provided by means of a straight tungsten rod 2.4 mm. in diameter and 20 cm. long, with a glass screw fused on, and arranged to rotate at from 300 to 1000 revolutions per minute. In alkaline solutions, a coating of glass is spun over the exposed surface of the tungsten in order to protect the metal. To prevent loss of liquid by spraying, a hard rubber disc with a convex lower surface carries the terminal screws for the electrodes and fits closely over the beaker of 200 to 400 c.c. capacity containing the electrolyte. A small disc electric heater is placed under the beaker. A number of these cells are connected in parallel in the electrical circuit, which provides current at 15 volts. A separate rheostat with each unit enables the current to be separately adjusted with each cell.—J. N. P.

Mercury ; Detection of — in chemico-legal cases. C. L. Spica. Gazz. Chim. Ital., 1917, 47, 11., 139—144.

SEPARATE portions of fresh visceral material were immersed in 95% alcohol and treated with 1 c.c. of 4% mercuric chloride solution and with 0.5 gm. of pure calomel. After 2 years' exposure to

diffused light the flasks were opened, the contents filtered, the insoluble matter washed with water and then treated successively with 10% hydrochloric acid, 10% nitric acid, and hydrochloric acid and potassium chlorate. It was found that the mercuric chloride had been largely converted into a compound (probably albuminate) not extracted by dilute hydrochloric acid, though only a small amount was not extracted by the successive treatments with the acids and potassium chlorate. Doubtful reactions for mercury were obtained with the alcoholic filtrate from the material in contact with calomel, but a considerable quantity of the calomel had been transformed into a compound (probably albuminate) which was soluble in dilute hydrochloric acid, and most of which could be isolated as metallic mercury by electrolysis of the solution. Some of the calomel also remained in an unaltered condition, or at least in a form in which it was not soluble in hydrochloric or nitric acid.—C. A. M.

Germanium; Qualitative detection of — and its separation from arsenic. P. E. Browning and S. E. Scott. *Amer. J. Sci.*, 1917, 44, 313—315.

THE authors have modified Buchanan's method of separating germanium from germaniferous zinc oxide containing lead, cadmium, arsenic, and traces of selenium. A mixture of the oxide with a little potassium permanganate, manganese dioxide, or potassium chlorate and 10—15 c.c. of concentrated hydrochloric acid is distilled, and germanium sulphide precipitated from the distillate with hydrogen sulphide. 0.1 gm. of zinc oxide containing 0.21% of germanium, gave a distillate from which a distinct precipitate of germanium sulphide was obtained with hydrogen sulphide. The method was successfully applied to show the presence of germanium in argyrodite previously decomposed with nitric acid and evaporated to dryness. 0.0001 gm. of germanium is easily detected in the presence of 0.2 gm. of zinc oxide, and 0.00006 gm. gives a satisfactory test in the presence of 0.025 gm. of zinc oxide. The following modification of Winkler's method of separating germanium and arsenic is recommended:—A solution of the sulphur salts formed by fusing the mineral with sodium carbonate and sulphur is treated with ammonium acetate, acidified with acetic acid, and treated with hydrogen sulphide. The arsenic is completely precipitated, and the germanium remains in solution.—F. Sp.

Official Notice.

THE NITROGEN PROBLEM AND THE WORK OF THE NITROGEN PRODUCTS COMMITTEE.

A Memorandum having the above title has just been issued by the Munitions Inventions Department. The substance of the Memorandum is given below.

The nitrogen problem.

The manufacture of the vast quantities of explosives that have been called for by the present conditions of warfare has led to an unprecedented demand for various nitrogen compounds. The world's consumption of nitrogenous fertilisers appears practically to double every ten years, and in 1913 had attained the large figure of 2,500,000 tons of Chile nitrate and about 1,400,000 tons of ammonium sulphate.

With the outbreak of war, the demand for explosives became of paramount importance and the requirements of agriculture for the time being took a secondary position. The prospect of world shortage of food, however, has served to bring the agricultural aspect of the problem again into the forefront. The researches of Sir William Crookes and the experimental work of Lord Rayleigh upon the fixation of atmospheric nitrogen by means of the electric arc, pointed the way to a method of utilising the unlimited supply of nitrogen in the air, and thus providing against the time when other natural sources of nitrogen compounds should have become exhausted.

The establishment on a very large scale during the past 20 years of processes for nitrogen fixation is one of the most striking electrochemical developments of modern times. Special reference may be made to the arc process as used in Norway, the Haber or synthetic ammonia process developed in Germany, and to the cyanamide process for the manufacture of nitrolim from calcium carbide, as carried on in Norway, Sweden, France, Italy, Germany and the United States.

In spite of the fact that the incentive to the commercial establishment of nitrogen fixation may be said to have originated in this country, no steps were taken in the United Kingdom to obtain nitrogen compounds other than cyanides synthetically. The ammonia recovered at gas-works and coke-ovens has constituted practically the only form of combined nitrogen produced in this country. During the war the command of the seas has hitherto enabled Great Britain to rely entirely upon importation for the whole of our supplies of nitrate of soda, the most important raw material of our explosives industry. The Central Powers, on the contrary, having been cut off from external supplies, were compelled to fall

back upon their internal resources, with the result that nitrogen fixation processes, some of which were established commercially before the war, have been developed upon an enormous scale.

Formation of the Nitrogen Products Committee.

Soon after the formation of the Munitions Inventions Department in August, 1915, proposals for the fixation of nitrogen began to be received from inventors. These schemes were referred to the Chemical Inventions Committee of the Advisory Panel, but as they were isolated applications of the general problem and were of limited scope, they did not immediately lead to any definite line of policy being taken upon the question. The importance of the problem was recognised, however, and the attention of the Minister was directed to it from time to time in the monthly departmental reports.

The inauguration of the submarine campaign in February, 1916, and the grave menace of overseas supplies of nitrates emphasised the importance of taking action on the matter. At this opportune moment a memorandum on the nitrogen problem was submitted to the Department by the Faraday Society. Several conferences were held to discuss the steps that should be taken, and as a result, the Nitrogen Products Committee was constituted in the following June. Members of the Advisory Panel, representatives of other Departments of the Ministry of Munitions and of the Government, and delegates of the leading scientific societies were invited to serve. The constitution of the Committee is as follows:—The Comptroller: Col. H. E. F. Gould-Adams, C.B., C.M.G., R.A. (Chairman), G. S. Albright (Chairman of the Processes Sub-Committee), W. R. Cooper, representing the Physical Society (Chairman of the Gas-Firing Sub-Committee), Sir James Dobbie, F.R.S., representing the Board of Agriculture and Fisheries (Chairman of the Economics Sub-Committee), Prof. A. K. Huntington, representing the Faraday Society (Chairman of the Experiments Sub-Committee), Sir John F. C. Snell, representing the Institution of Electrical Engineers (Chairman of the Power Sub-Committee), W. R. Bousfield, K.C., F.R.S., Dr. Charles C. Carpenter, Kenneth M. Chance, Prof. J. Norman Collie, F.R.S., Lieut.-Col. A. W. Crossley, F.R.S., representing the Chemical Society, Prof. F. G. Donnan, F.R.S., Sir Arthur Duckham, K.C.B., Dr. R. C. Farmer, representing the Explosives Department, F. Gossling, representing the Board of Trade, Dr. J. A. Harker, F.R.S. (Director of Nitrogen Research Section), F. H. Jones, Right Hon. Lord Moulton of Bank, K.C.B., F.R.S. (Director General of Explosives Supply), C. H. Merz, J. H. Rider, Dr. E. J. Russell, F.R.S., Prof. the Hon. R. J. Strutt, F.R.S., Sir R. Threlfall, K.B.E., F.R.S., A. J. Walter, K.C. (Ministry Representative on the Board of Trade Committee on Electrical Power Supply), Secretary to the Committee: R. T. G. French. Secretary to the Advisory Panel: H. W. Dickinson.

The terms of reference were:—

(1) To consider the relative advantages for this country and for the Empire of the various methods for the fixation of atmospheric nitrogen from the point of view both of War and Peace purposes: to ascertain their relative costs, and to advise on proposals relevant thereto which may be submitted to the Department.

(2) To examine into the supply of the raw materials required, *e.g.*, pure nitrogen and hydrogen, and into the utilisation of the by-products obtained.

(3) Since some of the processes employed depend for their success on the provision of large supplies of cheap power, to ascertain where and how this can best be obtained.

(4) To consider what steps can with advantage be taken to conserve and increase the national

resources in nitrogen-bearing compounds and to limit their wastage.

(5) To carry out the experimental work necessary to arrive at definite conclusions as to the practicability and efficiency of such processes as may appear to the Committee to be of value.

(6) As a result of the foregoing steps, to advise as to starting operations on an industrial scale.

An important advance was made when the then Minister of Munitions, the Right Hon. E. S. Montagu, M.P., met the Members of the Committee on October 10th, 1916. He assured them that the Government appreciated the importance of the nitrogen problem, and that he would do everything in his power to see that the recommendations ultimately made received the fullest consideration. At this meeting Sir William Crookes was present. At the same meeting the organisation of the Committee was completed and the following Sub-Committees were set up: Processes, Economics, Experiments, Power, and General Purposes.

At a later date another Sub-Committee was found necessary to deal with the question of coal distillation processes and the production and utilisation of power-gas. The Gas-Firing Sub-Committee was accordingly constituted. In all, the Committee and its Sub-Committees have held upwards of eighty meetings.

Nitrogen fixation research.

The necessity for research was evident from the outset and the Department at once took steps for the organisation of a suitable research staff and the acquisition of a laboratory. Fortunately, the co-operation of the authorities of University College was secured and a part of the new Ramsay Laboratory, at that time scarcely completed, was placed at the disposal of the Department.

The item placed first on the research programme was a complete investigation into the production of synthetic ammonia by the Haber process. This decision was influenced by the claims made for the process and by the commanding position it occupies in Germany, where the economic conditions as regards coal supplies and the comparative absence of water power are similar to those in Great Britain. Moreover, the almost complete lack of precise information concerning the commercial details of this process made it apparent that the research would present many unknown factors and was therefore likely to occupy a considerable time.

Towards the end of the year, the Committee came to the conclusion that the ammonia oxidation process was well adapted as an emergency measure for securing quickly a considerable output of nitric acid or nitrates. Although already working with more or less success upon the Continent, the process had not at that time been operated in this country. A systematic investigation of the most recent developments of the process was therefore undertaken.

Many important problems have arisen in connection with the two main researches indicated above. Reference may be made to such questions as the most efficient and commercially practicable catalysts for the synthesis of ammonia and for ammonia oxidation, and the commercial preparation in bulk and at a sufficiently low cost of hydrogen of the high degree of purity required for the synthesis of ammonia.

On account of the formidable technical difficulties presented by the different problems, it was obvious that a research staff of considerable experience in all the recent developments of physical chemistry was needed for carrying quickly to a successful issue the work of the research programme. In the selection of the personnel, therefore, endeavour was made to obtain men possessed of special qualifications.

The Department has been fortunate in securing a number of such men, with the result that the progress made has been more rapid than might have been expected under the present difficult circumstances. It may be mentioned that the chemist responsible for the research on the synthesis of ammonia had the advantage of having previously worked for some time on the problem at Professor Haber's laboratory at Karlsruhe.

In December, 1916, when the research work was in its early stages, a demonstration and lecture took place at the Research Laboratory and was attended by representatives of the Explosives Supply Department and of the War Office, and by delegates and members of other Government Departments and of scientific societies. The Minister of Munitions was unable to be present, but early in 1917 he asked for practical recommendations to be submitted to him at an early date.

Interim report of the committee.

In view of the magnitude and complexity of the problem, the Committee was unable immediately to present a complete report. Certain definite conclusions had been arrived at, however, and these together with recommendations thereon, were embodied in a unanimous Interim Report which was submitted to the Minister of Munitions in February, 1917. The substance of the recommendations is given below.

(a) *By-product ammonia.*—The importance of increasing the output of by-product ammonia for munitions and for agriculture was pointed out. Steps were indicated whereby an increase could be obtained from existing gas-works and coke-oven plants. It was also recommended that action should be taken to avoid the loss of ammonia known to be occurring in certain districts.

(b) *Ammonia oxidation process.*—The erection at the earliest possible moment of plant capable of producing in the aggregate at least 10,000 tons of nitric acid per annum from gas-works or coke-oven ammonia was recommended.

(c) *Cyanamide process.*—The erection of a factory having an annual output of the order of 50,000 tons of cyanamide was recommended; the cyanamide to be utilised as such for agriculture or for the production of ammonia.

(d) *Synthetic ammonia process.*—The erection of a full-sized trial unit plant for synthetic ammonia process was recommended.

The Minister of Munitions invited members of the Committee to meet him, and the recommendations of the Interim Report were discussed in detail. At the conclusion of this meeting the Minister appointed a small Executive Committee to supervise the action involved in giving effect to his decisions, and to report to him from time to time upon the progress made.

The Minister's decisions and the action taken thereon.

The Minister's decisions were as follows :—

(a) *By-product ammonia.*—The Committee was requested to deal with the problem of conserving ammonia and of augmenting the output on the lines of the recommendations.

(b) *Ammonia oxidation process.*—The Ministry of Munitions would undertake the installation of one Government plant on the lines suggested, or, if the Committee so advised, the Ministry would agree to the erection of plants by suitable private firms. The information resulting from the research work was to be placed freely at the disposal of *bona fide* manufacturers, but was not to become the exclusive property of any firm or group of firms.

(c) *Cyanamide process.*—The Committee was requested to investigate the relative merits of a Government scheme and of other schemes that had been put forward involving private enterprise, and to submit a report embodying definite proposals.

(d) *Synthetic ammonia process.*—The erection of the full-sized trial unit was authorised.

In carrying out these decisions, the Executive Committee dealt first with the problem of conserving and increasing the output of by-product ammonia. The co-operation of the Controller of Coal Mines, of the Gas Companies, and of the domestic and industrial users of coke was enlisted, and the matter was then placed under the direction of the Explosives Department in March, 1917, in view of its existing organisation for dealing with the supply of ammonia.

The next step taken was to summon a conference of manufacturers likely to be interested in the ammonia oxidation process as a good deal of useful information had been collected regarding it and the research work had already reached a semi-commercial stage. Conferences took place at the Munitions Inventions Department in March, 1917, and were attended by representatives of a number of the more important interests. Several manufacturers at once agreed to take up the further study of the process with a view to its commercial development, and have since actively co-operated with the Department. Some of them have already erected experimental plant on a considerable scale.

Encouraging progress continued to be made with the research, and arrangements and plans were made for the erection in London of a trial plant consisting of a single commercial unit designed to give an output of one ton of strong nitric acid per day. At this stage the work of establishing the process on a commercial scale for the manufacture of nitric acid and ammonium nitrate was handed over to the Explosives Department at their request in August, 1917. The work of investigation, however, has been continued at the Research Laboratory as several important aspects of the process still remain to be explored.

With regard to the manufacture of cyanamide, the Executive Committee came to the conclusion that the schemes involving private enterprise did not adequately fulfil the ends in view and recommended the erection of a factory by the Government. The Committee proceeded to collect further information on cyanamide processes in actual operation, and representatives proceeded overseas for this purpose. Complete details of a scheme involving a large-scale factory with electric power station are now in course of preparation for submission to the Minister of Munitions.

Meanwhile a considerable amount of work had been carried out in connection with the synthesis of ammonia, including a detailed investigation of the whole of the conditions governing the process, and of the efficiency and life of numerous catalysts. These studies led to the devising of a method of working whereby the output of ammonia per unit of catalyst space has been increased to a figure, which, as far as is known, exceeds anything hitherto attained. The design and erection of a semi-technical unit apparatus embodying a number of novel features, with the necessary pumps, circulators, gas holders, etc., was then undertaken. It is expected that the operation of this unit, which is now at work, will enable the remaining problems as to the chemical engineering details involved in the design of the full-sized trial unit authorised by the Minister to be definitely settled.

Research upon the preparation of pure hydrogen in bulk has been carried on conjointly with the above investigations, and arrangements have already been made for the trial on a semi-commercial scale of a process that has given very promising results in the laboratory.

Nitrogen in sulphuric acid manufacture.

An important practical outcome of the conferences with manufacturers has been the intro-

duction of ammonia oxidation plant to take the place of the nitre-pots used in the manufacture of sulphuric acid by the leaden chamber process. In pre-war times, the annual consumption of Chile nitrate for this purpose amounted to 18,000 tons. With the present increased output of sulphuric acid the consumption is greater, so that the possible saving of overseas freight is appreciable.

One of the small converters designed in and made for the Departmental Research Laboratory has been installed at the sulphuric acid works of Messrs. Brunner, Mond and Co., and has been working satisfactorily for some months. The firm is now arranging to adapt similar converters to the whole of their leaden chambers. The United Alkali Co., the South Metropolitan Gas Co., and others are making arrangements to adopt the process, and are utilising two types of converter to the Laboratory designs. Drawings have also been placed at the disposal of the Explosives Department for the benefit of other controlled establishments.

The apparatus is compact; the expense involved in its installation, apart from ammonia purification plant, is comparatively small, and its operation is simple. Arrangements have therefore been made for the rapid manufacture of the converters likely to be required, since it is believed that these designs may become standard types for the purpose in question. An explanatory pamphlet, compiled by the Research Staff and embodying detailed information concerning the construction and operation of the converters, will be available shortly for the use of firms who have already taken up the process or are desirous of doing so.

Further research.

Up to the present date the research has practically been confined to the two processes mentioned above and to problems arising therefrom. The investigations of the Committee have shown, however, that many important and promising fields still remain to be explored.

Under present circumstances, all activities have been concentrated upon processes which have a possible value as war measures and no attempt has been made to extend the programme of research beyond such limits. In view, however, of the national importance of the nitrogen problem both now and in the future, it is hoped that definite arrangements will be made to preserve the continuity of the research after the war.

The importance of cheap electric power.

It was realised from the outset that the generation of electric power at a cost decidedly lower than has hitherto been attained in this country was a vital factor if an attempt was to be made to establish certain of the nitrogen fixation industries in Great Britain on a sound economic basis from the point of view of post-war competition. A thorough enquiry has therefore been made as to the possibility of cheapening the production of electric power from coal, not only by its generation in bulk with the most modern plant, but also by the use of methods involving carbonisation and gasification, with recovery of the ammonia, fuel oils, and other by-products hitherto wasted when raw coal has been directly used. The Sub-Committees concerned have had the advantage of obtaining the personal views of a number of experts who attended to give evidence on different aspects of the problem. This enquiry has been distinctly fruitful, and much detailed information has been collected.

Schemes for the utilisation of various undeveloped water powers in the British Islands for nitrogen fixation have also been submitted and have been carefully examined. At least one of these schemes for hydro-electric development on a considerable scale presents *prima facie* prospects

of becoming a valuable national asset. The Power Sub-Committee recommended that a survey should be made of the drainage area in question with a view to confirming the details of the scheme as submitted. The survey has recently been completed and is expected to result in the formulation of a definite development scheme for the utilisation of this water power. It is estimated that the engineering work involved will take about two years to complete, and the scheme is therefore to be regarded as a post-war measure.

Costs of operating nitrogen fixation processes.

Since many of the nitrogen fixation processes have not only a value for munitions but also a post-war importance, endeavours have been made to investigate the probable requirements of this country for nitrogen products. A detailed examination has been made of the production, consumption, imports and exports of such products, and special consideration has been given to the question as to the relative order of the costs involved in operating the synthetic and non-synthetic processes.

Most of the information relating to synthetic processes has had to be obtained from foreign sources, and the Committee has been able to secure many figures of an authoritative character. The information thus collected has been subjected to critical examination in the light of manufacturing experience in allied industries and conclusions have been arrived at as to the costs likely to be incurred under British conditions.

The magnitude of this part of the enquiry may be measured when it is stated that the Committee is in possession of comprehensive data concerning the cost of manufacture of:

- (a) Nitric acid and nitrates by the older methods, and by the arc and ammonia oxidation processes;
- (b) Calcium carbide and cyanamide;
- (c) Ammonia and ammonium sulphate by the Haber and cyanamide processes;
- (d) Hydrogen and nitrogen;

as well as concerning the costs involved in operating the Chili nitrate and the by-product ammonia industries.

Co-operation with other Government departments.

Realising that many of the branches of the Committee's activities related to problems which were also occupying the attention of other Government Departments, an attempt has been made to secure as far as possible co-operation and interchange of information. Thus, on the question of the carbonisation of coal, an exchange of views has taken place with the Fuel Research Board. On the question of the production of hydrogen on a large scale at the lowest possible cost, a problem of great importance in connection with aeronautics, collaboration in experimental work with the Admiralty has been arranged. It will be noted that the constitution of the Committee has provided for liaison with the Explosives Department, the Board of Agriculture, the Board of Trade, and a number of scientific societies.

Nitrogen fixation in the British Empire.

In accordance with the terms of reference the final report of the Nitrogen Products Committee will include a review of the nitrogen problem as it affects the British Empire. This branch of the work has not yet been fully dealt with, but representations have been made to the Dominions, to Dependencies (through the Colonial Office), to Egypt, and to India informing the Governments concerned of the activities of the Committee, and offering to place at their disposal all the information in the possession of the Department.

As a result of the negotiations thus instituted, the Department is already in direct touch with official representatives of the Governments of Australia, Canada, New Zealand, South Africa,

Egypt and Mysore, and also with important developments in other parts of India.

Nitrogen fixation in allied countries.

An interesting event was the visit to this country in February, 1917, of a delegation from the recently constituted Commission de l'Azote acting under the French Ministry of Munitions. It was soon evident that the delegation was most immediately interested in the various processes already established in this country for the manufacture of ammonium nitrate, and a visit of inspection to many of the controlled establishments was accordingly arranged through the Explosives Department.

Several conferences with the delegates were held at the M.I.D. during their stay in this country and an interchange of ideas and information took place upon the most recent developments in nitrogen fixation in France and Switzerland. The entente thus established has been maintained by the periodical exchange of information and documents between the French Ministry of Inventions and the Munitions Inventions Department.

The Allied Governments of Italy and Russia have also nominated representatives to act in liaison with the Department upon the nitrogen problem. The developments already accomplished in the countries in question have enabled these liaison officers to afford immediate and valuable assistance.

The action taken by the United States Government on the nitrogen question is also worthy of notice. Under the National Defence Act of 1916, a sum of £4,000,000 was set aside for the establishment in the United States of nitrogen fixation on a large scale. Committees of the Academy of Sciences, and afterwards of the Ordnance Department were set up. Their advisers visited England, and the more important nitrogen fixation installations on the Continent outside Germany. Upon the recommendation of their experts, the U.S.A. War Department has decided to erect forthwith works for the manufacture of synthetic ammonia by a modified Haber process. A statement concerning the activities of these Committees and setting forth the decisions arrived at was recently published.

Final report of the Nitrogen Products Committee.

The various Sub-Committees set up by the Nitrogen Products Committee have already completed or are now engaged upon their final reports. There will then remain the report of the Main Committee, which will of necessity be a somewhat detailed document owing to the scope of the enquiry that has been undertaken. Endeavours are being made to expedite the last stages of the work so that the final report may be available at the earliest possible date.

Trade Report.

SOUTH AFRICAN INDUSTRIES.

The first issue of a new journal has just made its appearance, under the title, "The South African Journal of Industries." The journal is issued under the authority of the Minister of Mines and Industries, and forms a means of conveying to the public the results of the work of the Department. The need for such a journal has been accentuated since the appointment of the Scientific and Technical Committee, which, in addition to dealing with questions of industrial research, is

engaged in the preliminary work of preparing an economic survey of the natural resources of South Africa; to this end reports are being prepared by authorities on the various subjects, and these will be published in the journal.

The journal is to be issued on or about the 15th of each month, price 5s. per annum, post free within the Union. Subscriptions should be sent to the Government Printer, Pretoria.

There are a number of interesting articles and papers in the issue now under notice. H. Warrington Smyth, Secretary for Mines and Industries, contributes a paper on "The beginning of organisation for industrial expansion," in which he enumerates the facts which led up to the formation of the Industries Advisory Board and the Scientific and Technical Committee, and indicates briefly the work to be carried out by these bodies. Extended reference is made to the Report of the Dominions Royal Commission, appointed in 1912. The Acting Director of Census (C. W. Cousins) contributes some notes on the 1917 Census of Manufacturing Industries, which is now in progress of taking.

The mineral production of the Union is dealt with, based on figures extracted from the Annual Report of the Government Mining Engineer for 1916. This Report shows that the total value of the mineral production was £43,531,009 in 1915, and £50,593,359 in 1916. Increases in the values of nearly all the products are reported; diamonds account for an increase of over £5,300,000, and notable increases are also seen in the output of asbestos, antimony, lead, and corundum.

The subject of industrial alcohol and the manufacture of motor fuel in the Union is discussed. Legislation has now been made whereby Union spirits, suitably denatured, may be used as motor fuel without payment of excise duty. Either for use in making motor fuel may also now be made from Union spirits without excise duty being paid thereon. Motor spirit must be coloured blue, green, or violet by means of a suitable dye-stuff. The conditions to be observed in the manufacture of motor fuel are enumerated.

J. Burt-Davy, in "Notes on the use of ground limestone as a fertiliser," refers to the increases in crop yield obtainable on all soils save "alkaline" soils by the application of finely-ground limestone.

"Industrial possibilities of the Zuurpruim" are discussed. The kernels of the fruits (*Ximenia Americana*), examined at the Imperial Institute, contained 3.4% of moisture and yielded 65.6% of oil to light petroleum and 65.8% to acetone. The oil is non-drying and could probably be used for lubricants, soap-making, etc., but it is very viscous. The residual meal contained 38.8% of crude proteins, 5.3% of fat, and 38.1% of starch, and is intermediate in "food units" between linseed meal and decorticated cottonseed meal. Feeding trials in Germany are stated to have shown, however, that the meal is not well suited for use as a feeding stuff and further experiments on this point are being conducted.

"South African buchu" is dealt with by Dr. E. P. Phillips, who describes the cultivation, preparation and adulteration of the substance, and gives details of exports from South Africa and the prices obtained.

Articles on "South Africa's great opportunity," by C. D. Leslie, "Encouragement of South African industries," by A. Aiken, "The economics of agricultural production in South Africa," by R. A. Lehfeldt, and "Increase of food production," are also included.

The journal concludes with two book reviews, some interesting short notes, and a "black list" showing articles imported into the Union during the first seven months of 1917, which it is considered are capable of being produced in the Union.

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council desires to remind intending competitors for the Cross and Bevan prize that Essays must be received at the offices of the Society before the close of the present year.

The Essay prize is open to all members of the Society who are British subjects. The Research Grant is limited to competitors under 25 years of age at the time of sending in the essay.

Full particulars were published in the issues of the Journal for 15th January and 15th and 28th February, 1917.

PROHIBITED EXPORTS.

By an Order-of-Council, dated 27th November, 1917, the following headings are deleted from the list of prohibited exports* :—(B) Asbestos and articles manufactured wholly or partly of asbestos; (C) Cascara sagrada; (B) Cinchona bark; (C) Formic acid; (C) Iridium compounds; (C) Osmium compounds; (C) Palladium compounds; (B) Quinine and its salts; (A) Radium compounds; (C) Rhodium compounds; (C) Ruthenium compounds; (B) Fats, all animal and vegetable, and articles and mixtures containing such fats, not otherwise prohibited; (B) Fatty acids and articles and mixtures containing fatty acids; (C) Iridium and its alloys and manufactures containing iridium; (A) Lubricants, mineral, and articles and mixtures containing mineral lubricants; (B) Lubricants, not otherwise specifically prohibited, and articles and mixtures containing such lubricants; (A) Mica block and mica splittings; (B) Mica sheets, mica waste, mica powder, micanite, and articles made from and insulating materials containing mica in any form; (B) Oils, animal, not otherwise specifically prohibited, and articles and mixtures containing such oils; Oils, vegetable, the following, and articles and mixtures containing such oils :—(A) Castor; (A) Coconut; (A) Colza or rapeseed; (A) Cotton seed; (A) Ground nut; (A) Linseed; (A) Palm kernel; (B) All other vegetable oils not otherwise prohibited; (A) Oleaginous kernels, nuts, seeds, and products not otherwise specifically prohibited; (C) Osmium and its alloys and manufactures containing osmium; (C) Palladium and its alloys and manufactures containing palladium; (C) Rhodium and its alloys and manufactures containing rhodium; (C) Ruthenium and its alloys and manufactures containing ruthenium; (A) Turpentine substitute, and articles containing turpentine substitute.

The following headings are added :—(A) Asbestos and articles manufactured wholly or partly of asbestos; (C) Araroba or Goa powder; (C) Areca or betel nuts; (C) Arecoline; (C) Buchu leaves; (C) Calabar beans; (C) Cascara sagrada and its preparations; (C) Chrysarobin; (A) Cinchona bark, its alkaloids and their salts; (C) Coca

leaves; (C) Colocynth; (C) Cubebs; (C) Cuprea bark; (A) Formic acid; (B) Indian hemp (*Cannabis indica*); (B) Iridium compounds; (B) Osmium compounds; (B) Palladium compounds; (A) Radium and its compounds; (C) Rhatany root; (B) Rhodium compounds; (B) Ruthenium compounds; (C) St. Ignatius beans; (C) Soda, nitrite of; (C) Squills; (A) Fats, all animal and vegetable, and articles and mixtures containing such fats, not otherwise specifically prohibited; (A) Fatty acids and articles and mixtures containing fatty acids, not otherwise specifically prohibited; (B) Iridium and its alloys and manufactures containing iridium; (A) Lubricants, not otherwise specifically prohibited, and articles and mixtures containing such lubricants; (A) Mica block, mica sheets, and mica splittings; (B) Mica waste, mica powder, micanite, and articles made from and insulating materials containing mica in any form; (A) Oils, fixed, all animal and vegetable, and articles and mixtures containing such oils, not otherwise specifically prohibited; (A) Oleaginous kernels, nuts, seeds, and products of all kinds; (B) Osmium and its alloys and manufactures containing osmium; (B) Palladium and its alloys and manufactures containing palladium; (C) Parchment; (B) Rhodium and its alloys and manufactures containing rhodium; (B) Ruthenium and its alloys and manufactures containing ruthenium; (C) Saponaceous berries (soap nuts and saparita), barks and roots; (B) Terebene, and articles containing terebene; (A) Turpentine substitute, not otherwise specifically prohibited, and articles containing such substitute; (C) Vellum.

On and after the 7th day of December, 1917, the heading "(B) Coal, except coal allowed by the Commissioners of Customs and Excise to be shipped as bunker coal" will be deleted and replaced by the heading "(A) Coal, except coal allowed by the Commissioners of Customs and Excise to be shipped as bunker coal."

FINANCIAL FACILITIES FOR TRADE AFTER THE WAR ESPECIALLY IN RELATION TO RAW MATERIALS AND CONVERSION OF WORKS.

The Lords Commissioners of H.M. Treasury and the Minister of Reconstruction have appointed a Committee with the following terms of reference :

To consider and report whether the normal arrangements for the provision of financial facilities for trade by means of existing banking and other financial institutions will be adequate to meet the needs of British industry during the period immediately following the termination of the war, and, if not, by what emergency arrangement they should be supplemented, regard being had in particular to the special assistance which may be necessary—

(A) To facilitate the conversion of works and factories now engaged upon war work to normal production.

(B) To meet the exceptional demands for raw materials arising from the depletion of stocks.

The Committee will consist of the following :—

Sir Richard V. Vassar-Smith (Chairman of Lloyds Bank and President of the Institute of Bankers), Chairman of the Committee; Sir John Bradbury (Joint Permanent Secretary to H.M. Treasury); Mr. A. E. L. Chorlton (Director of Ruston, Proctor & Co. Ltd., Agricultural Machinery Manufacturers); Mr. E. Brocklehurst Fielden (Deputy Chairman of the Lanes, and Works.

* The prohibition of exports is as follows :—

Goods marked (L), to all destinations;

Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

Railway, and a former Member of Parliament for the Middleton Division of Lancashire); Sir Algonon Firth (Chairman of the Associated Chambers of Commerce of the United Kingdom); Mr. Robert Fleming (Chairman of several well-known Investment Trust Companies); Mr. A. C. D. Gairdner (Managing Director of Union Bank of Scotland, Glasgow); Mr. Frederick C. Goodenough (Chairman, Barclay & Co., Ltd., Bankers); Sir Alex. McDowell, K.B.E. (Member of the firm of Carson and McDowell, Solicitors, and well-known in the linen trade); Sir Alexander Roger (Ministry of Reconstruction; formerly Director-General of Trench Warfare Supply Department at the Ministry of Munitions); Mr. John Sampson (Representative of the Controlled Establishments Association); and Mr. A. W. Tait (Member of the firm of G. A. Touche & Co., Chartered Accountants, and Director of a number of large commercial undertakings).

EXPORTS OF COAL.

The Coal Exports Committee directs the attention of coal exporters and others to the fact that the Order-of-Council issued on 27th November prohibits on and after 7th December the export of coal to all *British* destinations abroad except under licence. Firms wishing to ship coal to such destinations after 6th December should therefore apply on the proper forms (which can be obtained from the Collectors of Customs at the coal ports, or from the War Trade Department (Coal Division), 3, Central Buildings, Westminster, S.W.1) for the necessary licences, in the same way as in the case of shipments to Allied and neutral countries.

DEALINGS IN POTASSIUM COMPOUNDS.

Under the Order, dated 17th October, restricting dealings in potassium compounds (this J., 1917, 1969), no person may offer to purchase, purchase, or take delivery of certain potassium compounds except under and in accordance with the terms of a licence issued on behalf of the Minister of Munitions by the Controller of Potash Production, and no person may offer to sell, sell, supply or deliver any such compounds to any person other than the holder of a licence and in accordance with the terms thereof. The Controller of Potash Production now announces that until further notice he licenses the purchase by any person of potassium compounds coming within the terms of the Order, notwithstanding that such purchases may exceed an aggregate of 3 lb. per month, *provided that the compounds so purchased are used solely in B.P. form or in B.P. preparations for purely medicinal purposes.* By this general licence, retail druggists, hospitals and similar institutions, medical men and others are relieved of the onus of applying for individual licences to purchase compounds coming within the conditions indicated in italics above, and wholesale druggists and others may supply such compounds for use as above set out without the necessity of verifying that the purchaser holds an individual licence to purchase or take delivery. It will, however, be necessary for the wholesaler, in making his returns to the Controller, to state the aggregate amount and value of his sales of compounds for purely medicinal purposes during the period covered by each return. Special forms of return will be provided for this purpose. All sales of compounds other than those exceeding 3 lb. aggregate per month per person, and the sales for medicinal purposes hereby licensed, must be conducted strictly under purchasers' licences as prescribed by the Order, and, together with an aggregate statement of sales under 3 lb., and for medicinal purposes, must be brought out on the returns as at present.

METALLURGICAL COKE.

The Minister of Munitions has made an Order dated 27th November, ordering that the war material to which Regulation 30A of the Defence of the Realm Regulations applies shall on and after 17th September, 1917, include metallurgical coke of the following classes and descriptions:—Scottish, Nottinghamshire, Lincolnshire, Cumberland.

SUGAR (BREWERS' RESTRICTION) ORDER, 1917.

An Order, issued by the Ministry of Food, dated 19th November, prohibits the use by brewers of any saccharine substance other than solid glucose or the invert or other produce of low-grade cane sugar polarising not over 8.9, and from which not less than 40% of its weight has already been extracted in the form of grocery crystal sugar, honey sugar, or syrup. Brewers are, however, permitted to use their existing stocks or any sugar which was already, at the date of the Order, in transit to them from the manufacturers. The quantity of such saccharine substances that brewers are permitted to use is not more than 40% of the quantity used by them in the year 1915.

SUBSTITUTION OF GAS FOR PETROL AND PETROLEUM.

It is officially announced that the following appointments have been made to the Gas TrACTION Committee which the Government recently decided to establish:—Chairman—Sir Boverton Redwood, Bart. (Director of Technical Investigations, H.M. Petroleum Executive); Major Aston McNeil Cooper-Key, C.B. (H.M. Chief Inspector of Explosives, Home Office); Sir Evan D. Jones, Bart. (Petrol Controller, Board of Trade); Mr. H. H. Law, C.B., M.Inst.C.E. (Chief Engineering Inspector, Local Government Board); Sir Arthur Churchman, Bart. (Controller of Mineral Oil Production, Ministry of Munitions); Mr. W. Doig Gibb (Technical Adviser on Gas Works Products, Ministry of Munitions of War); Dr. Chas. C. Carpenter, M.Inst.C.E. (Ministry of Reconstruction); Mr. Edward S. Shrapnell-Smith (Chairman of Joint Committee of Mechanical Road Transport Associations, Economy Officer H.M. Petroleum Executive); Mr. James Ollis (Chief Officer, London County Council Public Control Department); Lieut-Colonel R. K. Bagnall-Wild, R.E. (Member of Technical Committee of the Motor Industries and President of the Institution of Automobile Engineers); Mr. F. W. Goodenough (Chairman of Executive Committee of British Commercial Gas Association, and member of National Gas Council); Alderman William Kay (Chairman of Manchester Corporation Gas Committee and member of National Gas Council); Mr. George W. Watson, M.Inst.Mech.E. (Inspecting Engineer to the Commercial Motor Users' Association, Incorporated); and Mr. W. Worby Beaumont, M.Inst.C.E. (Technical Adviser to the Commissioner of Police of the Metropolis).

The terms of reference are: To consider and report upon—

1. The employment of gas in substitution for petrol and petroleum products as a source of power, especially in motor vehicles, and the manner in which such gas may be supplied, stored, carried, and used, with due regard to the safety of the public.

2. The action, if any, which should be taken by the Government to encourage and safeguard the use of gas for this purpose.

Mr. Shrapnell-Smith has consented to act as Secretary for the time being, and until further notice all communications should be addressed to him at 8, Northumberland Avenue, London, W.C.2.

STANDARDISATION OF PETROL GAUZE.

The Controller, Department of Aeronautical Supplies, Air Board Office, announces that considerable trouble and delay has been experienced in obtaining a regular supply of petrol gauze, primarily due to the fact that aircraft contractors depended upon importation for the finer mesh required for this very important accessory of aeronautical engines, and it was found that a wide variety of mesh was called for by different manufacturers, although they required the mesh for similar purposes, and in some cases it was very difficult to justify distinction. For instance, the difference in the width of the aperture between 200-mesh gauze and 180-mesh gauze is only 1-10,000th of an inch. There has been a tendency to call for meshes much finer than are justified by the conditions. This has resulted in the use of gauze which is much more fragile than is necessary or desirable. To overcome this difficulty, the Air Board took the leading manufacturers of wire cloth into consultation, and the Royal Aircraft Factory experts made certain experiments, which has resulted in a standardised gauze being agreed upon. This will greatly facilitate manufacture, and will enable the material to be produced in Great Britain in adequate quantities to meet the demands from aircraft factories. The gauze will be known as "Air Board Standard Petrol Gauze," and all orders and enquiries should be sent to the Air Board Office, S. (M.A.) 5, Room 609, Strand, London, W.C.2.

USE OF OLIVE OIL IN PRODUCTION OF WOOLLEN AND WORSTED GOODS.

The Army Council have made the following Order, under date 4th December:—

1. No person, the business carried on by whom consists wholly or partly in the production or manufacture of woollen or worsted goods, shall, after 15th December, 1917, without a permit issued by or on behalf of the Director of Raw Materials, apply, or cause to be applied, any olive oil for the production of tops or yarn.

2. No person hereinbefore defined shall, without a permit issued by or on behalf of the Director of Raw Materials, apply, or cause to be applied, any olive oil for the production of tops in quantities exceeding two-thirds of the standard recognised by the Bradford Conditioning House.

CEYLON MONAZITE SANDS AND OTHER THORIA MINERALS.

The Principal Collector of Customs at Colombo reports, under date 15th October, that an official statement has been made to the Ceylon press respecting the mineral survey which has been conducted in Ceylon in co-operation with the Imperial Institute. The survey, it is stated, has led to the discovery of beach deposits of monazite sand which will usefully supplement the commercial supplies of thoria required for the manufacture of incandescent gas mantles. Samples of the sand have been investigated by the Imperial Institute, and the results have been so promising that the Ceylon Government has arranged to work the deposits. Details of the arrangements are

not yet available, but suitable British concentrating machinery has been selected by the Institute for the purpose, after experimental trials, and will shortly be shipped to Ceylon. At one time the monazite deposits in Brazil were the only commercial source of supply of thoria, and these were controlled by the German Thorium Syndicate. The monopoly enjoyed by this Syndicate was subsequently threatened by the discovery of extensive deposits of monazite in the native State of Travancore in India, which are so rich that samples examined by the Imperial Institute were found to contain nearly twice as much thoria as the Brazilian monazite. The German Syndicate, however, obtained control of the company formed to work the Indian deposits, and they continued to exercise a dominating influence over the industry until the outbreak of the war. Since then the company has been reconstructed and given a British character, and it is understood that another portion of the deposits in Travancore has been taken up and will be worked by a second British company. The work of the mineral survey has shown that Ceylon can furnish several other thoria minerals besides monazite. Among these is thorianite, the richest known source of thoria. This new mineral when it was put on the market was sold in Ceylon at as high a rate as £1600 per ton, but the deposits have proved to be limited.

THE STANDARDISATION OF DECINORMAL SULPHURIC ACID.

BY FRID. W. BABINGTON, B.A., AND ALFRED TINGLE, D.Sc.

(Abstract.)

The usual method of standardising sulphuric acid solutions by means of barium chloride is open to serious objection on account of the occlusion of soluble salts by barium sulphate and also because the method measures total sulphates in solution. The first source of error can be obviated partially or entirely by particular methods of operation involving much attention to minute details, but the second objection is fundamental.

The authors have therefore sought a rapid and accurate method, for which the necessary reagents can easily be obtained in a state of purity. The best procedure is considered to be to select a suitable acid and compare its solution volumetrically with the acid to be standardised.

Oxalic acid is not very suitable for the purpose as it is seldom free from ash and is liable to contain variable amounts of water.

H. Kastle (Amer. Chem. J., 1910, 44, 817) has recommended the use of *p*-nitrotoluene-*o*-sulphonic acid or *p*-amino-*o*-sulphobenzoic acid, but these acids are not readily available to most analysts.

Succinic acid has also been recommended, but Phelps and Hubbard (this J., 1907, 554) state that it requires long and careful purification.

The authors consider that either tartaric acid or salicylic acid is suitable for the purpose, both being cheap and readily obtained in a state of purity, whilst further purification can be easily effected if necessary. Further, both of the acids are anhydrous and have fairly high mol. wts., and neither is liable to change on storage when dry. A disadvantage attaches to each, however. Salicylic acid can only be used in alcoholic solution, whilst tartaric acid is subject to change if its solutions are kept for too long.

A number of experiments were made in which approximately decinormal sulphuric acid was titrated against approximately decinormal caustic soda solution which had been practically freed from carbonate by addition of barium chloride. Decinormal solutions of tartaric and salicylic acids were also titrated against the caustic soda solution. The results for these acids agreed exactly.

The sulphuric acid was then standardised by addition of barium chloride in slight excess, using the ordinary precautions and, in another series of tests, taking every care to ensure thorough washing and freedom from barium sulphide. The results of these tests agreed well among themselves but were somewhat higher than those obtained in the tests with tartaric and salicylic acids. Results, more concordant with the latter, were, however, obtained by adding excess of barium hydroxide solution to the sulphuric acid, acidifying with hydrochloric acid and weighing the barium sulphate. Extremely low results were obtained when the sulphuric acid was exactly neutralised by means of standard barium hydroxide solution, using phenolphthalein as indicator, and the resulting barium sulphate weighed.

The barium hydroxide solution was examined by two methods. In one, excess of sulphuric acid was added to the solution and the whole evaporated to dryness and ignited in a platinum dish, and in the other sulphuric acid was added in excess and the precipitate washed, dried, and weighed. The results of the first method were higher.

In further experiments on the exact neutralisation of sulphuric acid with barium hydroxide a variety of indicators was used, and the amounts of barium hydroxide solution used and barium sulphate obtained were noted. The following results were obtained, 25 c.c. of sulphuric acid being used in each case:—

TABLE I.

Indicator.	Vol. of barium hydroxide used.	Weight of BaSO ₄ obtained.
	c.c.	gm.
Phenolphthalein	12.05	0.2735
Lucmold	12.05	0.2765
Cochineal	12.05	0.2797
Rosolic acid	12.20	0.2775
Methyl orange	12.00	0.2780

Thus the weight of barium sulphate obtained is not constant, nor is it proportional to the volume of barium hydroxide solution from which it is derived.

The results of all the experiments are summarised in the following table, in which the strength of the sulphuric acid solution is expressed in terms of the barium sulphate obtained from 25 c.c. as determined by various methods.

TABLE II.

Method.	BaSO ₄ obtained.
	gm.
1. Titration in comparison with tartaric acid	0.2924
2. Titration in comparison with salicylic acid	0.2921
3. Direct precipitation with barium chloride	0.2949 (mean)
4. Direct precipitation with excess of barium hydroxide	0.2915 (mean)
5. Exact neutralisation with barium hydroxide (using phenolphthalein)	0.2735
6. Evaporation of Ba(OH) ₂ with excess of acid and calculation from titration	0.2868
7. Addition of excess sulphuric acid to Ba(OH) ₂ and titration, with calculation from titration	0.2837

Methods (1) and (2) agree perfectly, and method (4) agrees fairly well with them, so they are probably correct. The divergence of method (3) from (1) and (2) cannot be due to the presence of sulphates in the sulphuric acid, since this would cause a high result in method (4), hence it is probably due to occlusion of barium chloride, which would not occur to any great extent in method (4). It should be noted that any method of standardisation of decinormal or weaker solutions of sulphuric acid involving weighing of barium sulphate is liable to larger experimental error than titration, since 0.1 c.c. of N/10 acid is only equivalent to 1.17 mgrm. BaSO₄.

Method (4) is not recommended, owing to the trouble experienced in preventing the barium sulphate from passing through the filter. The low result obtained with method (5) is due to incomplete precipitation, since the other possible source of error (presence of alkaline impurities in the barium hydroxide solution) is unimportant as shown by comparison with methods (6) and (7). The discrepancy between (4), (6), and (7) seems best accounted for by supposing the presence of an alkaline silicate. The results of methods (6) and (7) seems to reflect considerably on Richardson's method (this J., 1907, 78).

Further experiments were made in connection with the variations of the neutral point as shown in Table I. The same solutions were used as before, the barium hydroxide being clear and free from carbonate except that present in solution. The subjoined table shows the results obtained, using 10 c.c. of sulphuric acid in each case (the figures of the first two columns have been calculated from those for 25 c.c.). In the first four sets of tests the alkali was added to the acid and in the fifth the acid to alkali:—

TABLE III.

Indicator.	Alkali solution used.				
	Barium hydroxide.	N/10 sodium hydroxide.	N/20 sodium hydroxide.	N/20 NaOH - excess NH ₄ Cl.	N/20 sodium hydroxide neutralised by acid.
	c.c.	c.c.			
Phenolphthalein	8.30	9.48	18.60	—	19.20
Lucmold	8.30	9.59	18.90	18.30	18.90
Cochineal	8.30	9.46	18.80	18.80	18.90
Rosolic acid	8.32	9.52	19.10	—	19.10
Methyl orange	8.24	9.12	18.60	18.60	18.60

The solutions used were not standardised, so that the figures in the various columns are not in all cases comparable. It is suggested that the abnormality in the titration of sulphuric acid against sodium hydroxide may be due to the absorption of carbon dioxide during titration. The authors do not agree with Smith's suggestion (this J., 1917, 415) that the irregular results are due to the presence of carbonates, since it is unlikely that the solubility of barium carbonate in the solution used is so great as to cause errors of such magnitude. Also the neutrality as shown by lucmold agrees with that shown by phenolphthalein and not with that shown by methyl orange. If carbonates been present, lucmold indications should differ from those with phenolphthalein and agree with those of methyl orange. For similar reasons it is believed that ammonia was not an important factor.

Meeting held at Liverpool University on Friday,
November 16th, 1917.

MR. A. T. SMITH IN THE CHAIR.

MODERN MARGARINE TECHNOLOGY.

BY W. CLAYTON, M.S.C.

The introduction of new and extensively used foodstuffs has often synchronised with periods of great wars. Thus condensed milk was first used in large quantities by the Northern Armies in the American Civil War, in 1856, and soya-beans and bean oil were developed as a result of the Russo-Japanese War, when the Japanese soldiers found soya-bean products a staple war-food. Margarine is pre-eminently a war product, having its inception during the Franco-Prussian War, and finding its place as a universal article of diet during the present great struggle.

Margarine manufacture is really a present-day success, with a seemingly prosperous future ahead. It is cheap, made from quite pure materials, having excellent food values, and simulates butter very closely. The former prejudice against its use is rapidly breaking down, and to-day the industry is very promising indeed, and many new works are being established, pointing to keen competition after the war.

When, in 1869, the French Government offered a prize for a cheap butter-substitute, to conform as closely as possible in physical and chemical characteristics with butter, and of good keeping qualities, a French chemist, Mège-Mouriès, began a research into the formation of fat in milk. He reasoned that in the animal metabolism, the carbohydrates are converted into fat, which in turn changes into butter-fat by the process of pepsin-digestion. This led him to try to effect artificially a similar change in animal fats. Fresh beef fat, usually from the kidney or intestines, free from tissue, was digested for two hours at 45° C. in an aqueous solution of sodium carbonate, in presence of pigs' or sheep's stomachs. As a result of pepsin action, the fat was completely separated from the remaining tissue; it was then skimmed off, and warmed with a 2% solution of common salt to prevent early rancidity. On standing, a yellow fat separated which was cooled to about 22° C. The semi-solid mass possessed a butter odour, and when pressed between warmed plates, the more fluid constituent was obtained, averaging about 50 to 60% of the fat. This fat, when cooled, had a butter-like consistency, and was termed "Oleo-margarine," being sold as such in Paris.

Mège-Mouriès improved on this product by churning it with 10% of cow's milk, and water containing macerated cow's udder (0.4%), until a satisfactory emulsion was obtained. This was solidified, washed, salted, coloured, and sold as a butter-substitute, having a moisture-content of about 12.5%, and a m. pt. of 17°—20° C.

Factories were erected and developed in Austria, and later, in 1873, an English patent was taken out by Hippolyte Mège. The Parisian Council of Hygiene, in 1873, sanctioned the sale of these butter substitutes, at the same time prohibiting their claim to the title "butter."

The name "Margarine," derived from the Greek word for "pearl," was introduced by Chevreul, who applied it to the compound formed by the union of margaric acid and glycerin, as found in human fat and in olive oil. It is not certain whether "margarine," as thus understood, is a definite chemical compound, for whilst some chemists regard $C_{17}H_{31}O_2$ as margaric acid, a

definite member of the stearic series of fatty acids, others claim it to be merely an eutectic mixture of stearic and palmitic acids.

Adopting Chevreul's nomenclature, the oleo-margarine described above was thus considered to be a mixture of oleine and margarine, the stearine matter having been removed.

In 1887, the Margarine Act was passed, and all butter substitutes thenceforth had to bear the title "Margarine." To comply with the requirements of the Food and Drugs Act, it is now necessary to attach a margarine label, printed in 1½ in. letters, to any package exposed for sale. If the packages are exposed for sale in a box, it will suffice for the word "Margarine" to be printed on the lid, and in that case, the packages must be handed to the buyer enclosed in a wrapper bearing only the one word, "Margarine," in ½ in. block letters.

Since the time of Mège-Mouriès, the manufacture of margarine has steadily progressed, numerous oils have been introduced, and up-to-date methods and machinery brought into vogue. The fat is no longer digested artificially, the flavour of butter being simulated in other ways. Also margarines from vegetable oils and fats have steadily displaced the former purely animal products.

The chief animal fats employed in margarine manufacture are lard, oleo, "premier jus," and stearine. "Premier jus," obtained from the best beef fat, can be fractionated to yield oleo and stearine, e.g., by hydraulic pressure at 38° C., using filter-cloths, or by fractional crystallisation for some days at 28° C. By the former method, the more fluid oleo oil is expressed; in the latter, the harder stearine crystallises out.

Stearine is not used in large proportions in a margarine mixing because of its high melting point (54° C.), but is useful when vegetable oils preponderate, as it corrects the consistency of the final product. The corresponding mutton oleo, jus, and stearine are not in such demand, and their physical properties are somewhat different from their beef analogues, thus leading to changes in the composition of the margarine. A great variety of vegetable oils is employed. The solids or fats include coconut and palm-kernel oils, and in the United States palm oil is also used. The oils include cottonseed, arachis, soya bean, and sesame oils, and more recently kapok, maize, and wheat oils. Last, but by no means least, must be included hardened or hydrogenated oil, which will be discussed in some detail later.

The refining of oils for edible purposes has become a fine art, and almost any of the vegetable oils just mentioned can be obtained quite tasteless and odourless, and of a high analytical degree of purity.

Upon the relative proportions of these various oils and fats, both animal and vegetable, depend the quality and texture of a margarine. It may be taken for granted that where much animal fat is used, a dearer brand of margarine results, and that the cheapest brands are almost entirely vegetable in origin. The formulæ or compositions employed depend upon the quality required, the market condition prevailing, and the weather. In warmer weather, more of the solid constituents will be used.

The introduction of hydrogenated products in margarine manufacture marks a great technical advance, and one which is likely to develop very rapidly in the future. The fundamental principle underlying the hydrogenation of oils and fats, is to make valuable hard fats from relatively cheap raw material, by the addition of hydrogen. By the addition of about 1% of hydrogen to cottonseed oil, for instance, a fatty product of at least the consistency of lard may be obtained. Since hydrogenation can be stopped at any time, it is obvious that with a given oil, an end product of any desired melting point up

to that of the fully saturated product is possible. Hydrogenated oils have excellent keeping qualities and are said to help margarine in this respect. Knapp found no rancidity in samples of such oils even after 18 months, and the free acid content (0.7% as oleic acid) remained practically constant. An objection has been raised by Brauner that hardened oils raise the moisture content of a margarine, owing to their property of retaining water, much in excess of what other oils do. He claims to have proved this on a large scale on many occasions. As far as I am aware such a difficulty has not been met with in our factories, and in any case, the problem admits of very easy solution.

The use of hardened oils really hinges upon their edibility or otherwise, and on this point much controversy has raged. Little doubt exists as to their being thoroughly suitable for human consumption, since they are assimilated during human metabolism just the same as any other fats, but whether the traces of metal catalyst almost invariably present affect the health, was for a long time a dubious matter.

Nickel is the most widely-used catalyst and traces of it are to be found in most samples of hardened oils. The amount of this metal likely to be present depends on the amount of free acid in the oil, and on the time of actual contact of oil and catalyst. Bömer found in a sample of hydrogenated sesame oil containing 2.5% fatty acid, an ash content of 0.01% with 0.006% of NiO. Again, a whale oil with 0.3% fatty acid, had an ash of 0.006% with 0.0045% NiO. Thus if a daily quantity of 100 grms. of hardened oil were eaten, the maximum amount of nickel absorbed would be 0.6 mgrm. Physiological tests show this quantity to be quite harmless: in fact it has been proved that small daily doses of nickel powder have no ill effect, 99.8% of the metal being rapidly excreted.

Another objection that has been raised against the use of these oils in margarine manufacture, is that good products may be prepared from bad raw material. As a particular instance, whale oil can be hydrogenated to yield a tasteless, odourless, and germ-free fat, physiologically harmless. Suspicion was aroused that margarine manufacturers might use cheap and unwholesome fish or other oils, hardened to form good clean products. Much controversy has centred round this point. So long as the raw material was unsound, the public would not sanction the final margarine. Maybe there will be a legal fixing of the raw material in the future. At any rate, such a course has been frequently advocated, especially in the United States.

Milk is used in margarine manufacture for two primary reasons, viz.: as a basis for flavouring development and as an emulsifying agent. Only milk of a high hygienic standard should be employed, either fresh-skimmed or separated. It is an ideal medium for micro-organisms, containing, as it does, the essentials of life in a readily assimilable form. The micro-organisms present in milk are lactic and butyric bacilli, various yeasts and moulds, and pathogenic organisms. For the destruction of the undesirable bacteria, especially of the pathogenic type, the milk is pasteurised by heating to 82° C. for a few minutes. The chemical and physical properties of the milk were not considered to be seriously affected, until quite recently when Renshare and Ware showed that there is a rapid decrease in the amount of sugar, and an increase in acidity, on pasteurising milk. The lactose is decomposed by certain lactic organisms which act very rapidly at 80°–85° C., producing lactic acid, part of which is probably transformed into other substances, since the acid

found never exceeds one-third of the amount of lactose decomposed.

By heating to 82° C. the milk is deprived of some useful souring bacteria, but also has its content of undesirable and pathogenic organisms reduced. A Government Report of 1914 by Delépine states that the bacterial content of 1 gm. of milk was reduced from 14,120,000 to 1900 in one case and from 5,770,000 to 100 in another. Much discussion has taken place as to whether the tubercle bacillus in milk is killed during pasteurisation. Richmond, in his work on "Dairy Chemistry," p. 282, says, "As the tubercle bacillus is comparatively easily destroyed by heat, pasteurisation of milk may be resorted to to destroy the organisms: keeping the milk for 15 minutes at 70° C. will practically remove the source of infection." Delépine states that he is convinced "that cream infected with human tubercle bacilli was not invariably sterilised when exposed to a temperature of 85° C. even when the exposure lasted 15 minutes." He continues: "I subsequently obtained similar results with milk containing tubercle bacilli of bovine origin."

Unfortunately the complete sterilisation of milk by boiling is prohibited, inasmuch as the characteristics of the milk would be too much changed, and a burnt flavour would result. It is very probable, however, that in the near future pasteurisation will be replaced by complete electrical sterilisation, a method which would leave the physical and chemical and flavouring characteristics of the milk unaltered and would be ideal from the margarine manufacturers' standpoint. Milk can be sterilised by means of a high tension alternating current, and such a method has been patented. It should also be possible to have a large scale ultra-violet ray apparatus to sterilise milk at ordinary room temperature, just as Dornae and Daire sterilised water using quartz electric lamps. Butter and fats have also been rendered germ-free, by being carried on an endless band or a revolving drum in a thin layer, past a series of ultra-violet ray lamps. In any case, the future holds much in store for changing this part of a margarine process involving the incipient reduction of all the bacteria in the milk.

In the present system of pasteurisation, the milk is well agitated, and delivered, after being pasteurised, about 8 feet above the inlet level, thereby enabling a vertical cooler to chill the milk as it descends to the souring tanks. By cooling to about 10° C. bacterial activity is inhibited and the action of germs which have resisted heating, or have gained accidental access, is minimised. It now becomes necessary to inoculate the milk with those germs necessary to develop a butter-like flavour. A pure culture, or "starter," is added, consisting of lactic acid bacilli. The temperature is raised to a point known to be favourable to the bacterial development, and lactic fermentation proceeds until a degree of acidity is reached which causes rapid precipitation of curd. The milk is again cooled to a safe inhibiting temperature, at which it is maintained until required in churning.

Lactic fermentation gives the milk a pleasant acid taste and aroma, due to the production of lactic acid, among other products, but the true flavour of butter is lacking. Much research has yet to be done before margarine can be made having a distinct and recognisable odour and taste like butter. Some manufacturers add flavours of various kinds when blending the final margarine, but this is only a temporary expedient. The true flavour will be obtained when the requisite bacterial action on either milk or fat is discovered. Personally I foresee a time when milk as a flavouring basis will not be required. Research should be

directed somewhat along the lines of Mège-Mouriés' ideas, towards a pre-digestion of the fats to butter-fat, or else to a selective bacterial action on both animal and vegetable fats. Water and an emulsifying agent could then replace milk. My own experience leads me to a quite optimistic view of probable progress in this direction.

The milk having been prepared for churning, it is now necessary to emulsify the oils with it. According to the quality of margarine desired, a mixture of animal and vegetable oils and fats is melted in large vessels, in which the temperature can be adjusted by means of steam or cold water. The melted mixture passes through strainers to a temper-room, where a constant suitable temperature can be maintained for each given mixture. This, however, is not really a necessary procedure; all temperature adjustments can be made just as well in the melting room, and then the oils are run straight to the churns.

Two types of churn are in general use. The older is a double-jacketed vessel which may be heated by steam, or cooled by water, as necessary, and is provided with stirrers, *e.g.*, two sets of revolving baffle-plates. The oil or milk is added, the other constituent is then run in. Sometimes both oils and milk flow in together. Efficient stirring at a suitable temperature is maintained, until emulsification is satisfactory. The emulsion is then released through a valve at the bottom of the churn, and flows on to a slanting shoot, where it is immediately met by a spray of ice-cold water, striking upon it with such force as not only to cause instant solidification, but also to break up the mass into yellow granules. These so-called "crystals" float down the shoot in the excess water, and collect in a wooden trough beneath, which permits complete drainage of the absorbed water.

The newer type of churn is electrically controlled, and is of the "continuous" type, *i.e.*, milk and oils are led by separate pipes to a thermo-regulated chamber, where on intermingling, numerous blades, rapidly revolved by means of a motor, effect complete emulsification, the emulsion being discharged as soon as formed, on to a shoot as already described. Alterable pumps allow regulation of the flow of milk and oils, so that various mixtures may be employed, according as one quality or another is desired. This electric or continuous churn is coming into great favour, and is far in advance of the older type.

In some factories the ice-water spray is not employed. Instead, the emulsion is solidified on a well-cooled revolving drum, and the solid margarine stripped off automatically.

The process of emulsification is of first importance. The object of churning is to imitate the emulsion found in cream and milk, where the fat globules have diameters ranging from 0.01 mm. to 0.0016 mm., and remain as discrete particles. The general theory of emulsification indicates that with two immiscible or only partially miscible liquids, two types of emulsions are possible, each constituent being in turn the disperse and then the continuous phase. For concentrated emulsions a third agent is required. Where oil is to be the internal of disperse phase, the emulsifying agent should be capable of lowering the surface tension of the external or continuous medium, and should be viscous, as is glycerin, or an emulsoid, like gelatin. If oil be dispersed in water, a stable emulsion can be made, the stability depending on the minuteness of the oil drops, this in turn being a result of the efficiency of the emulsifying apparatus. If, however, water be dispersed in oil, a very unstable system is produced, separation into two layers taking place as soon as beating-up ceases. Now milk, by virtue of its colloidal

content, is an excellent emulsifying agent, when oil is the disperse phase. Consequently if milk be in a churn in bulk, and oil is slowly fed in, with continuous agitation, an excellent emulsion of great oil concentration can be produced, and will set to a homogeneous mass afterwards. But if, as in some factories, oil be in the churns in bulk, and milk is fed in, a very unstable system results, which easily separates into layers on stopping the agitation for a while. This has been proved many times, and the explanation seems clear. To get a suitable emulsion of water in oil, one would require an emulsifying agent which should form an oil-soluble colloidal solution, but in milk the colloids are water-soluble. Both theory and practice condemn any form of churning which would lead to emulsions with oil as the continuous medium. Such emulsions when cooled by ice water, or on drums, solidify with clot formation, and the resultant margarines are "spotted" in texture. It is interesting to note that the electric continuous churn gives a stable emulsion of oil in milk, as would be expected from theoretical principles.

The temperature of churning is very important, and, other things being equal, about 25° to 35° C. should be the rule. Higher temperatures lead to milk curdling, and consequent spotting of the finished margarine by casein clots. Also one must remember the very delicate relationship between flavour and temperature.

Though some technologists still maintain that fats of high-melting point like stearine lead to imperfect emulsification, and consequent poor texture in the final margarine, it is possible to work under such conditions as to obtain eminently satisfactory emulsions. Conditions are known which allow even fairly large quantities of stearine to be mixed with low-melting vegetable oils, and yet give homogeneous and permanent emulsions.

Investigations have been made to increase artificially the efficiency of emulsification by the addition of various colloids to the milk. Starch, gelatin, glycerin, egg-yolk, lecithin compositions, and numerous patent mixtures have been tried. These substances have been regarded as forming a membrane or film around the oil globules and so preventing their coalescence, thus leading to increased stability of the emulsion system. At the same time, it must not be forgotten that the electric charge on the particles may also play a large part in preventing coalescence. Still, whatever the ultimate explanation, it is a fact amply proved by experience, that the addition of so small a quantity as 0.1% of, say, glycerin or gelatin to the milk before churning, leads to much better emulsification. Where the ice-water spray system is used, the starch, gelatin, or other reagent is washed out, and cannot be detected in the final margarine. This is a decided advantage from the manufacturer's point of view. The rapid cooling and crystallisation of the emulsion inhibits separation, and also serves to absorb the minute casein particles associated with the fat globules.

The yellow "crystals" are removed to a maturing-room, where, under constant thermal conditions, the bacteria introduced by the milk can develop. This occupies many hours, depending upon the quality of the margarine being made. The best animal margarines are permitted the longest maturing time. Maturing accomplished, it is now necessary to knead the "crystals" together to form a coherent, butter-like mass, and at the same time to expel the excess of water, since the legal limit of moisture in margarine is 16%. Consequently the matured "crystals" are rolled in drums, or passed between a set of rollers. The following are typical analyses of two different churnings of "Alpha" brand, an animal margarine, where 100 gallons of soured milk was emulsified

with 1 ton of oils. The crystals were passed through a roller apparatus.

	Fat, %.		Water, %.	
	(1)	(2)	(1)	(2)
Crystals	67.30	67.30	27.46	27.47
Rolled product	78.38	80.23	16.03	12.47

The average amount of water in the crystals is 33 %, and in the rolled product, 14.5 %.

The buttery mass is now passed on to the blending department, where it is prepared for delivery to the consumer. The blenders hold various amounts of margarine and are fitted with curved blades, which by rapid revolution ensure thorough mixing of the margarine with salt, colouring matter, preservative, etc., in about 35 seconds. The amount of salt and colour to be added is determined by the consumer. The quantity of butter added, as a means of ensuring nicer flavour and better texture, must not exceed the legal limit of 10 %. Preservative, usually boric acid, is added in amount not exceeding 0.5 %. This provides against undue bacterial action, whereby acidity would develop, and cause rancidity.

The following analyses are instructive, and show that the acidity of a margarine is closely related to its milk content. The figures show the number of c.c. of N/10 caustic soda required to neutralise 10 grms. margarine melted in water, using phenolphthalein as indicator :—

	Before rolling		After rolling.	
	N 10NaOH	H ₂ O	N 10NaOH	H ₂ O
Brand A (a) ..	0.62	35.9%	0.33	18.3%
" (b) ..	0.58	34.2	0.26	10.9
" Δ ..	0.48	33.1	0.25	12.2
Irish butter ..	—	—	0.22	15.1

To illustrate how the acidity of a margarine would develop were no preservative added, the following figures may be cited. In this case the margarine was melted in alcohol and titrated against N/10 NaOH.

	Initial. 24 hrs. 48 hrs. 72 hrs.			
Brand D	2.17	2.50		2.66
" E	1.90	2.52		6.80
" F	2.63	2.86	3.71	4.80
" G	2.96	3.02		3.00*
	2.96	3.05		5.48†

* Kept in the cold store.

† Kept in the maturing room.

The acidity, as measured by the water-soluble acids, is practically a constant in each case.

When the margarine has been blended, it is packed, labelled, and passed into the cold-storage until required for shipment.

In order to improve the texture of a margarine, the addition of 0.5 to 5 % of a wax such as ceresin wax has been suggested. Glycerin has been used in this connection to impart a glossy appearance to the margarine. Glucose has been used, but Zoffmann has showed it to be injurious, owing to yeast fermentation leading to formation of carbon dioxide and bursting of the packages. Personally

I see no need for the addition of anything in the blending of a margarine in order to improve texture. If the process of emulsification is controlled properly, and the right conditions observed for even those cases where stearine and other high-melting fats are used, the texture will take care of itself.

Analytically, the difference between butter and a margarine is soon found by a determination of the soluble and insoluble volatile fatty acids, the so-called Reichert-Meisssl and Polenske numbers. But it has been urged that for a rapid and easy differentiation, some chemical reagent be added to a margarine. Thus Soxhlet suggested the use of phenolphthalein. In some countries, it is fixed by law that sesame oil to the extent of 10 % be a constituent of margarine, this oil permitting of a rapid and distinct colour test.

Frothing and browning being characteristics of butter on heating, and margarine simply spluttering and separating into water and oil on similar treatment, it is usual when blending, to introduce some substance which will bring about frothing and browning, when even low quality or pastry margarines are heated. Amongst the many things proposed and in use are butter, milk powder, casein, lecithin, yeast, malt-extract, cholesterol, egg-yolk, lactic acid, and many patent emulsions of lecithin and sesame oil.

The advent of artificial milk is a distinct advance in margarine technology, and one likely to have far-reaching consequences. It is fairly easy to imitate milk in so far as it is an emulsion of oil in water; it is just as easy to go a step further and add lactose and mineral matter to the emulsion, to strengthen the similarity. But to imitate milk successfully, the casein constituent must be introduced, and this proved the stumbling block for many years, in all attempts to produce a synthetic milk. However, casein-bodies have been extracted from nuts and nut-meals by means of alkaline media such as phosphates and carbonates, and artificial milks have been made from which cream, margarine, and cheese have been successfully produced. Here then is a new field, comparable with the introduction of hardened oils.

For the margarine manufacturer, having the oils, and possibly the oil-cakes too, at his command, may produce milk artificially, pasteurise it, and then flavour it by means of a culture, and so be quite independent of the dairy-farms.

The margarine industry is new, but in its short life many advances have been made. There is no doubt at all but that the industry will prosper, and as its scientific principles become more and more exploited, and its technology more developed, the place of margarine as a permanent and staple article of food will be more and more recognised.

DISCUSSION.

The CHAIRMAN, in opening the discussion, pointed out the stimulation of chemical industries by the French Government, who had offered prizes for margarine research on the one hand and had also commemorated the name of Leblanc in a similar manner. It was further interesting to note the interdependence of sciences like chemistry and biology in margarine manufacture.

Mr. COLLINGWOOD WILLIAMS was of the opinion that at the present time no butter was being added to margarine, although the law allowed up to 10 %. "Synthetic milk" could not be made successfully until the necessary enzymes were produced in the laboratory, which was at present an impossible achievement. A test to distinguish between butter and margarine was to examine a thin layer of the fat under the microscope, using polarised light, when margarine showed a crystalline appearance.

Dr. E. F. ARMSTRONG said that the controversy centred round the occurrence of traces of nickel catalyst in margarine was of Continental origin, and traces of metal were found in Continental brands of margarine owing to the technical inexperience of the firms using the "hardening" process: British hydrogenated oils contained practically no nickel. Concerning the production of good edible fats from cheap raw material like low-grade whale-oil, he did not think it was successful, and, in fact, it was not commercially used. The difference between margarine and butter depended on the content of mixed glycerides; these were difficult to identify and determine, and research in this field would help to advance margarine manufacture.

Mr. W. MANSERIDGE thought that an artificial milk industry would benefit margarine manufacture, since the natural product was comparatively costly on account of transport, etc., although in countries like Holland the much cheaper water carriage enabled milk to be carried from farm to factory at low cost.

Mr. CLAYTON, in reply, mentioned that the polarised light test failed in the case of "renovated" or "process" butter. A German chemist had published the results of some work on the hydrogenation of bad oils, using aluminium compounds as catalysts, and producing a fairly pure fat; this had roused public suspicion, and much controversy had ensued. No hardened fish-oils were used in the British margarine industry.

London Section.

Meeting held on Tuesday, December 4th, 1917.

DR. CHARLES A. KEANE IN THE CHAIR.

THE ECONOMICS OF COAL PRODUCTION.

BY PROF. HENRY LOUIS, M.A., D.Sc.

When the Chairman of the London Section asked me to open the present session with a paper, I was naturally faced with the difficulty of selecting a suitable subject, since it happens that the only branch of chemical industry upon which I can claim to speak with any of the authority of experience is one in which relatively very few of the members of this Section are at all interested. I therefore propose to submit a short review of a subject which will in my opinion appeal not only to every manufacturer, whether engaged in a chemical industry or otherwise, but further, to every citizen of the United Kingdom, whilst it is also peculiarly appropriate to the "Canny Town," which I have the honour of representing in this Society.

It is too often overlooked that Britain's greatness is built essentially upon the foundation of an abundant and cheaply gotten coal supply, and it is impossible to doubt that when this supply shall fail us, the hour of Britain's decadence will have struck. Coal is not merely one of the chief articles of British export, but it is practically the sole material product that we have for exportation. Not only do we export coal directly

as cargo or in bunkers, but also indirectly: when American cotton is converted in this country into piece-goods or Spanish iron-ore into machinery for exportation abroad, we are really re-exporting the raw material that we imported, plus the coal that has been consumed in its manufacture. Whether we export the coal as such, or export the products of the energy developed by the combustion of that coal, makes no real difference to the economic position as far as the coal is concerned. The real reason why we have become successively the world's chief manufacturer and the world's chief common carrier, is because we had available an immense supply of coal that could be extracted more easily and more cheaply here than in foreign countries. Every manufacturer knows how important an item in costs is the expenditure on energy and on fuel, and is aware that if this should increase seriously, competition with foreign nations would become hopeless. Our future depends essentially upon our ability to maintain this supply of cheap coal. Having regard to the enormous importance of the question, I think it well worthy of adequate discussion, and it appears to me that the first step towards any discussion of the problem is the presentation in clear form of the various items that enter into the cost of coal as supplied to the consumer; it is only when their significance is fully grasped, that it will be at all possible to forecast how these are likely to be affected in the future and how they in their turn will affect the problem as a whole.

The cost of coal at the pit's mouth may be taken as being made up of the following items:—

- (1) The value of the coal in its unsevered condition.
- (2) The cost of wages paid to the men engaged in its extraction.
- (3) The cost of the various materials and supplies.
- (4) Administrative and incidental expenses.
- (5) The profit of the colliery proprietor, including interest upon the capital employed.

I have attempted to calculate the proportions in which these various items contribute to the cost of coal at the pit's mouth, and have selected for this purpose the year 1913; the figures I propose to give are a rough average applicable to the United Kingdom as a whole; they will differ considerably in each coalfield, and individual collieries will show even wider variations; all that can be attempted is a general average applicable to the kingdom as a whole, and this is what I have endeavoured to compute. I make the ratios of the various items to be as follows:—

	%	s. d.
Royalty	5.35	0 6.5
Wages	62.55	6 4
Materials	16.45	1 8
Administration	7.00	0 8.5
Interest and profit	8.65	0 10.5
	100.00	10 1.5

According to the official figures the cost of coal at the pit's mouth averaged 10s. 1.5d. in 1913, and the costs given are calculated as percentages upon this total. It should furthermore be noted that the price of sea-borne coal delivered into barges in the Thames is given by the same authority as 21s. per ton.

To the cost of coal at the pit's mouth must be added further the cost of transport to the consumer, and in the case of the small consumer, who does not buy direct from the colliery, the merchant's profit.

I propose next to examine each of the items in some little detail.

The value of the coal in its unsevered condition, as it lies in its natural bed, is usually expressed in the form of a royalty; there are a few cases where collieries have purchased outright the seams that they are working, but in such a case the purchase price will have been computed as the present value of the royalties derivable from the coal, so that in either case it is the royalty that forms the basis of calculations. Practically all the coal in this country belongs to private mineral landlords, the leading exceptions being the coal in the Forest of Dean and under-sea coal, which belong to the Crown; in practice, however, the Crown deals with its mineral property just as any other mineral landlord would do, and there is therefore no need to consider the Crown ownership of coal apart from the general proposition. The story of how the ownership in this country came to be vested in mineral landlords is a long one, and one which I have dealt with elsewhere; here I need only say that it has in the vast majority of cases been acquired by strictly legal means and in return for services rendered to the community. I need only refer to the analogous case of the United States, where coal which originally belonged to the State has been handed over practically for nothing to citizens of the States, because it was held that only in this way could the national mineral resources of the country be rapidly and successfully developed, and that the indirect gain to the State by thus fostering national industries far outweighs any direct revenue that might have been obtained by retaining in the hands of the State the ownership of the coal resources of the nation. The startling rapidity with which America has taken the lead among the world's coal producers fully demonstrates the soundness of this policy.

I do, however, hold that in cases where deep-laying coal, of the existence of which neither the owner of the surface nor his predecessors in title could have had any inkling, has been discovered solely through the labours of a national institution, the Geological Survey of Great Britain, as has happened for example in Kent, the owner of the surface has no equitable right in the coal thus discovered. He has contributed no more to the discovery than has any other tax-payer, and I cannot see what equitable claim he has to the coal thus discovered for him. I hold that State mineral discoveries ought to be the property of the State; this principle has actually been admitted to some extent in the recently suggested legislation respecting discoveries of mineral oil, and in my opinion it should be extended to all minerals. Apart, however, from this very special case, I wish to make it clear that I look upon the ownership of coal by the mineral landlord as not only equitable but also as an advantage to the coal mining industry as well as to the entire community.

Upon the whole, the royalties charged are not exorbitant, and although occasional cases of extortionate charges or even of unwillingness to allow mineral to be worked at all may be quoted, there would be no difficulty in dealing with these, and generally speaking, the system works well and to the advantage of the country.

With regard to the amount of royalty, that is to say the price of the unsevered coal, there is little information since the 1889 Commission on Royalties made its report; that report showed that the royalties throughout the country amounted to about 5d. per ton; it is, however, probable that this figure would be a little low to-day,

and I consider that the figure that I have given of 6d. per ton is not very far from the mark. No doubt it will rise in the future under the effects of the mineral duties imposed by the 1909-10 Finance Act, an ill-considered piece of legislation which not only tends to increase the cost of the unsevered mineral, but also, by the way in which Increment Value Duties are imposed, directly discourages the development of our national mineral resources.

Wages form, it will be seen, the principal item in the cost of coal production. They are best considered under three customary heads: The labour at a colliery is usually divided into underground and surface, and the underground men are again sub-divided into hewers, who actually get the coal, and the other underground men, or offhand men as they are usually called. It need hardly be said that the proportions of these different classes vary within very wide limits from colliery to colliery according to circumstances; an average of wages taken over the whole country would probably give about the following proportions of wages for the total number of workers employed:—

Hewers	19
Offhand workers	32
Surface workers	19

The item of wages is obviously one of the greatest importance, forming as it does about 63% of the total cost at the pit's mouth; bearing in mind that the cost of materials represents very largely the value of the labour employed in their production, it is clear that wages represent more than two-thirds of the value of the coal at the pit's mouth, and that anything that can be done towards reducing the cost of the other items is of small significance compared to that of keeping labour costs within reasonable limits.

The cost of hewing must in some respects be considered apart from the other labour costs; hewers are always paid tonnage rates, whereas many of the others receive a datal wage, though some of them, e.g., putters who transport the coal underground, are generally paid by the ton. The hewing cost now forms no less than one-third of the cost of coal at the pit's mouth. This item has been continuously increasing for many years, and the increase has been enormously greater during the war than at any time previously. It is not to be expected, and most employers who have considered the question seriously do not even consider it desirable, that wages should ever come down to their previous level; most of us hold that the collier ought to have a standard of living higher than he has been accustomed to in the past; the only hesitation that attends increase in the rate of wages is that, as a rule, such increases in the past have not improved the status of the coal miner; he has only taken advantage of them to do less work. This feature is probably the most disquieting element in considering the future of British coal mining.

In the decade 1883-92, the average production was 320 tons of coal per worker employed.

In the decade 1893-02, the output was 295 tons.

In the decade 1903-12, the output was 380 tons.

No doubt to some little extent such decrease in production may be accounted for by the fact that the thicker and more easily worked seams are gradually becoming exhausted, and the production from the thinner seams is gradually forming an increasing proportion of the total, but the diminution in efficiency due to this cause should be far more than counterbalanced by the

increased use of underground machinery, especially of coal cutters and face conveyors, which greatly multiply the working capacity of the hewer. It cannot be too often or too emphatically stated that high wages can only be paid by an industry when they are really earned by the men engaged therein. In other words, the only solution that I can see for the difficulties of the position is to be found in an increased output per man. Hitherto the influence of the powerful Coal Miners' Unions has, to say the least of it, not been exerted in the direction of urging men to increase their production, and in this respect a reversal of policy on their part is an imperative necessity if Britain is to retain its position amongst the nations.

Offhand labour represents about 22% of the cost of coal at the pit's mouth; here it ought to be possible to effect decided savings, without, of course, decreasing the rate of wages; the adoption of mechanical means of underground transport on a more extensive scale, and reorganisation of some of the underground methods in use, appear to be quite possible. In the same way some saving might also be effected in surface labour; seeing, however, that this item represents under 12% of the total cost, the margin within which economies might be effected is comparatively small. The item of materials includes a large number of miscellaneous substances; the most important probably is timber used underground; it also includes the coal consumed in providing the necessary energy for working the pit, explosives, lubricants, and materials like rails, ropes, pipes, canvas, bricks, cement, etc., and the various items required for repairs and renewals. All these were, comparatively speaking, reasonable in price in 1913, and it is highly improbable that except as regards timber, economies in the quantities consumed can be effected in the future. On the contrary, the more extended use of machinery in the place of hand-labour is likely to involve greater costs under this head.

Administration includes a number of items, such as fees of directors, salaries of managers and secretaries, the cost of clerical work, of surveys, legal expenses, compensation for surface damage, rates and taxes (which form at present a very heavy item), wayleaves, etc. No great exception can be taken to any of these items except perhaps to that of wayleaves; the 1889 Royalties Commission determined the cost of wayleaves at about 3d. per ton on all coal raised in the kingdom, but it is probable that it amounts to about 3d. per ton at the present time. The effect of wayleaves is often overlooked, because most collieries group wayleaves and royalties under the same heading; the two are, however, really quite distinct. A royalty is, as I have shown, the purchase price of the unsevered coal, whereas a wayleave is rental paid for accommodation, namely, for permission to carry coal under, through or over someone's property. The price asked for it is usually the measure of what the colliery company can be compelled to pay, not of the damage suffered by the landowner. I cannot but think that this system of exacting wayleaves is inequitable, and that in this as in many other countries the right of an owner of minerals to transport these to some public means of communication should be held to be a servitude imposed in the public interest on the ownership of all land, and that the price to be paid for such passage should be assessed by an independent tribunal upon the basis of payment in full to the landowner of compensation for any injury that he may suffer by the transit of the mineral, but nothing more.

The amount of the colliery owner's profit, including in this term interest upon and redemption of the capital invested, is a subject that has been frequently discussed. At the present moment

the amount of capital invested in coal mines throughout the country is probably just about of the order of 10s. per ton of coal raised annually, and this figure is one that tends to increase.

Dr. J. B. Simpson, in his little work on "Capital and Labour in Coal Mining," written in 1900, considered that with an annual output of 200,000,000 tons, the capital invested was from 80 to 100 millions, and that the average return on this capital did not exceed 5%.

Dr. Simpson, in the above-quoted work, tabulates figures for the periods 1700 to 1759, and for 1866 to 1896, and Lord Joicey and others have based calculations upon the Board of Trade Report for 1901; putting these figures in the same form as those adopted above by myself for 1913, they may be tabulated as follows:—

	1700 to 1759.	1866 to 1896.	1901.
Wages	37.5	66.0	67.37
Materials and administration	25.0	17.0	16.54
Royalty	12.5	8.5	7.96
Profit	25.0	8.5	8.13
	100.0	100.0	100.00

The year 1913, which I have selected for illustration, happens to have been a particularly good year for the coal trade as prices were high and profits were above the average. In that year the selling price was approximately 10s. per ton at the pit's mouth, so that the profit would have been also 8.65% on the capital invested. It must, however, be borne in mind that this figure is the average that I have obtained from a number of collieries in successful operation, and that it therefore excludes all consideration of capital completely lost or sunk in unsuccessful ventures, i.e., not yielding a fair return: I am of opinion that Dr. Simpson's estimate of a return of 5% upon the whole of the capital expended in coal mining in the country, including successful and unsuccessful ventures, must be very near the mark, whilst as above said 8.65% is the average I have obtained from ordinarily successful concerns. It must be borne in mind that this return represents not merely interest on capital invested in a speculative business, but must also provide money to form a sinking fund to replace the amount of capital invested. Taking the average life of a colliery at about 39 years, and allowing for a sinking fund to accumulate at the rate of 3% (a reasonable rate for 1913), this would amount to a charge of about 23d. per ton of coal raised, or practically 2% off the profit above given, so that the real interest on capital paid by these successful collieries, allowing for redemption, is about 6½%.

Dr. Simpson considers that the average for the country, allowing for redemption, is about 3½%, a view in which most authorities concur, and which I also consider to be very near the truth.

It is necessary next to examine the cost of transport to the consumer, and it is self-evident that this must vary within the widest possible limits, according to whether the consumer lives next door to the colliery or a couple of hundred miles from it.

The cost of coal in the London market is an instructive example, and one which will probably be the most interesting to the present audience. In 1913, when the price of coal at the pit's mouth was given officially as 10s. 13d., the price of sea-borne coal in barges in the Thames was given also officially at 21s.

It is difficult to see how this latter cost is arrived at: the average freight from the Tyne to London during 1913 was 3s. 6-5d. per ton. Transport from the collieries to the steamer in the county of Durham may be averaged at between 1s. 3d. and 1s. 9d. per ton, including the cost of putting on board and trimming; discharging is included in freight. Tyne river dues are 1½d. Port of London dues 1½d., weighing 1d., so that the balance above cost, or say 5s. 3d., represents profits of the various merchants through whose hands it passes, and loss and waste in carriage. Coal carried by rail pays somewhat higher rates; probably it is a fair estimate that the average distance travelled by coal that comes into London by rail would be somewhere about 130 miles. Railway transport in this country is unquestionably expensive, a fact due to the conditions under which the English railway system has grown up; including the cost of waggons, which in most cases are the property of the colliery owners, terminal charges, etc., the average price per ton mile for the above distance should be approximately 0-9d. for household coals, and 0-75d. for manufacturing coals, so that I estimate the average cost of bringing coal by rail into London at somewhere about 9s. per ton.

Wastage in transit is a very serious item, and may range from 5 to 15%. Merchants' profits are quite considerable; I do not suggest that any dealer in coal in any stage makes unfair or exorbitant profits, but it would certainly appear that coal passes through an unnecessarily large number of hands between the pit and the consumer in many cases.

Reviewing now the various items that go to make up the cost of coal to the consumer, the obvious problem for the future is to determine whether reductions are possible, and where they are to be sought for. I think it is fairly evident that of the items above enumerated, neither the colliery proprietors' profit nor the coal-owners' royalty leaves much margin for reduction. Wages are obviously the largest item, and have been growing very rapidly, even before the war. Dr. Simpson, in his work already alluded to, states that in 1700 the hewer received for his wages one-twelfth of the selling price of coal, in 1800 one-eighth, in 1896 one-fifth, and in 1913, as shown above by myself, one-third.

If the rate of wages per day is not to go down to its previous level (and it is not in the least likely to), the only chance of reduction in this item would be by increased output; this might be obtained to some extent if it were possible to get the coal-miner to see that the only salvation for the industry in the future lies in increased production, or it may be brought about by the more extensive and better application of mechanical methods. In this country we have been relatively slow to adopt coal-cutting machines, but they have now gained a fair footing in the industry, and their use is extending yearly. The employment of coal-cutting machinery is a problem that cannot be treated in general terms, because the conditions of different coal seams vary within very wide limits, but there is little reason to doubt that in the future machines will be devised capable of being adapted to even the most widely varying conditions. In the same way mechanical means will no doubt be used to decrease the amount of off-hand and surface labour, these two items amounting together to nearly as much as the hewing cost by itself. There is but little hope that the cost of materials will come down very much; in fact, it is more likely to increase than to decrease in the future, not only because materials in themselves are likely to cost more, but because an increased use of machinery necessarily implies an increase in the employment of materials.

In an interesting paper by Dr. G. O. Smith and Mr. C. E. Lusher, on "The Cost of Coal (in America)," read before the American Mining Congress in November 14th, 1916, the authors write:—

"Anyone who is at all cognisant of the trend in the price of labour and material can see little hope of relief in lower costs for these items."

It may be of interest to point out that this conclusion, which quite agrees with my own, indicates how closely the American position resembles ours. Furthermore, it may be noted in passing that the distribution of items is not unlike our own; in the above paper certain figures are given, from which it can be calculated that the percentage of various items going to make up the net cost of bituminous coal in the United States averages as follows:—

	%
Labour	69
Materials	17
Administration	10
Royalty	4

The head of administration includes many items such as rates and taxes, which are beyond the control of the colliery company. In others, however, the possibility of certain economies is not excluded, and this is even more likely to be true of the charges incurred after the coal has left the pit's mouth. It may be suggested that one of the most promising methods of dealing with the situation would be by a close federation among colliery companies. If for instance all the collieries in a coalfield were federated and administered as one large unit, the costs of administration would be reduced, selling charges would be greatly decreased, because the elimination of competition would avoid the necessity for the numerous agents and merchants who are now maintained by the coal trade. Supplies could probably be purchased to better advantage and more cheaply by so large an organisation, and it could maintain a staff for the special purpose of conducting researches with a view to cheapening production on a scale that is impossible for the existing smaller companies. Above all, if the coal production of the country were concentrated in the hands of a very small number of large organisations of this kind, it would probably be possible to mark out definite areas within which other coalfields would refrain from competing, and thus reduce the amount of transport of coal to a minimum. Here again I am of very much the same opinion as the American paper that I have just quoted, which says:—

"In the item of transportation perhaps the most promising relief is that of reducing the length of haul." I have already pointed out that the cost of railway transport in this country is very high; if our railway conditions were like those of India, where coal is carried at 0-1d. per ton-mile, matters would be on a very different footing. We must, however, face the fact that any great reduction in the cost of railway carriage in this country is out of the question. One of the most promising modes of lowering the cost of coal to the distant consumer would be by reviving and improving the inland navigation of the United Kingdom. Unfortunately our canals have been neglected, and have mostly been allowed to fall into the hands of the railway companies, whose interest it has been rather to stop than to foster canal transport. Much interesting matter may be found in the Report of the Royal Commission on Canals and Inland Navigation of the United Kingdom, 1906; it appears that the charge per ton-mile by canal averages about 0-5d., whilst in the evidence of

Mr. W. H. Bartholomew before that Commission it is stated that the working cost of horse haulage is only 1-13th penny per ton mile; there would appear therefore to be a large field here in which improvements may be effected.

As I have pointed out previously, the item of waste is a serious one; here again economies might be effected by the operation of large units. If at all large coal receiving depots the fines and dust were collected and made into briquettes, these could be sold at the price of the best round coals, whilst the cost of their manufacture is not a serious item. This system of briquetting coal dust at receiving depots has been in vogue in Germany for a considerable time, and ought in my opinion to be adopted without delay in this country.

I do not, however, pretend to be able to do more than throw out a few suggestions indicating the possibilities of the future. That we cannot continue as we are for an indefinite period is to my mind quite certain. Whatever else may occur, I think it undoubted that we shall have to look forward to a period of most strenuous industrial competition when peace is restored, and that we shall be entering upon that competition under conditions less favourable than those which we have hitherto enjoyed, because our great accumulation of capital, which formed one of the main elements of national strength, will have been sadly diminished, and unless we are able to produce at least as cheaply as other nations, I see but little hope of retaining our former industrial ascendancy. This ability lies entirely within the power of labour to maintain or to destroy. The only solution that I can see for the problem lies not in low wages but in high production, which could probably be best stimulated by making wages dependent, not, as hitherto, upon prices, which labour cannot control, but upon output, which is wholly within control of the worker.

DISCUSSION.

Dr. CHARLES CARPENTER said that the fact that labour was the key of the whole question could not have been better emphasised than by the figures the President had given of the constant decrease in the output per man. The restriction of output by the workman was one of the most serious problems that had to be faced. Unfortunately most of the antagonism was based upon the idea that the future prosperity of the working man depended upon his output of work. This was observable not only in the unskilled trades, where one might expect to find it owing to lack of training and a somewhat lower standard of knowledge, but also in the highly skilled trades. Workers were imbued with the idea that the less they did the more work there would be for them. To what extent this feeling originated with the fear of unemployment it was difficult to say, but an allowance must be made for that fear when one considered the conditions under which labour mostly earned its living. One would have thought that the conditions through which the country was now passing would have opened the eyes of labour generally to the seriousness of that attitude, yet they knew it was not the case, and this showed how deeply rooted was the practice. With regard to the coal industry, it was the fact that a large amount of the coal brought to the surface was very badly cleaned, and the amount of dross and dirt in it now was much greater than in normal times. The reason was that, as in all other industries, there was a shortage of men and the ordinary labour for cleaning was not available. The war had shown that an enormous amount of work, even of the most strenuous kind, could be performed by woman labour; but the labour

of the picking belts was not of that arduous character. The coal travelled along a canvas band and there were pickers on either side who picked off the lumps of stone or dross. There was now not enough male labour to do this work, and the result was that dross was sent with and at the same transport cost as the coal. Cleaning was, however, work which women could easily do, but the unions were so short-sighted that they would not allow them to be employed on the belts. It was hardly conceivable that we were in the fourth year of the war and that a union so responsible, and which had produced such splendid men—he need only mention one, the Rt. Hon. Thos. Burt—should take up such an attitude. If the working man in industry took that short-sighted view he was afraid there was no hope. It did not matter whether we won the war or not—we should lose our future unless we could change this view of labour. How was it to be done? Had sufficient trouble been taken to teach labour its responsibilities in this matter? Had we begun as we ought to have done at the schools? Had we seen that the system of training and teaching was the right and proper one to bring up the young as good citizens? He was afraid we had done nothing of the kind. In a large majority of cases our education had been conducted on the cheapest and most narrow-minded lines, though it was vital to the progress of the nation as a whole. So that however we might blame labour we must bear a great deal of the blame ourselves. That was one respect in which employers, as well as the employed, must alter their practice. They must take more interest in their workers and get them to take more interest in the prosperity of their particular industry than they had done in the past. One point which he knew was controversial, but which should be mentioned, was the export of coal. He thought the authorities were now alive to the fact that the coal industry was a national one, using the word national in a bigger sense than it had been used in the past. There were responsible people concerned with problems of reconstruction who realised that fuel was one of the most vital of these problems, and that what was true of coal was also realised in regard to all minerals in the kingdom and the Empire. If the programme which he believed would be carried out was carried out, we should see as one of the fruits of reconstruction a broad-minded view in which all these possibilities were taken into account. Much had been left to private enterprise in the past. He believed it was true that there was no obligation to deposit records of borings which had been made in different parts of the country. Borings had taken place for minerals of one kind and another of which the State had no knowledge whatever. That, of course, was clearly wrong. The State ought to be in touch with every development of this kind which was going on. He thought in all probability there would be some method by which the search for or production of minerals, including coal, would be associated with some central authority. We should then not again do what we did at Travancore, where we turned the mineral rights over to the Germans because it was reported that the mineral there was not monazite but something else. Referring again to coal mining, the slow progress of mechanical coal cutting in Great Britain had not been altogether due to the mine-owners. There was the prejudice with regard to its use by the men and the general view of labour towards the carrying on of work by machinery. It thus became very difficult for the capitalist to put down machinery because the expressed policy of labour was that while the employers could put down the machinery, labour would regulate its effectiveness. He believed the attitude in the United States was different, and it would be interesting to know why the workmen there were

so very much more enlightened in that respect than they were over here.

Mr. ARNOLD LUTTON said with regard to royalties that hitherto the royalty which the landowner got was very moderate; 6½d. a ton was not high, and in England up to now royalties had been lower than in any other country in the world on the average. But the position was likely to be different. Years ago it had been possible to pick out quite a number of sites where coal could be found but now this was not the case. Landowners would get to know the value of their land and where there were different capitalists competing for land the royalty was likely to increase. The effect would be to raise the price of capital for coal mining and more harm would be done by the disturbance of confidence than was gained. Speaking with 30 years' experience, he suggested that the nation should buy up the coal-owners at a fair price. He did not think very much of the improvement of canals in this country because of the short distances concerned. There was no economy in sending coal by barge, and that was the reason why the canals were not very much used. It was different in Europe and America where the canals might be hundreds of miles long. With regard to boreholes, the Geological Survey officials were very diligent in finding out all the boreholes that were sunk and it was very difficult to put down a borehole without some official trying to find out what had been done and what had been discovered. But if anyone had spent £10,000 or £20,000 on ascertaining certain facts for their own private use he did not see why he should make everybody a present of that information.

Prof. J. S. S. BRAME said that the paper had removed certain misconceptions which had existed as to questions relating to economies in coal production, more particularly royalties and profits. Dr. Carpenter had mentioned the export of coal and he could not but think that this was a matter which was very intimately connected with the whole question and one which was certain sooner or later to become a very important question for consideration in this country. At the present time we exported one-third of our production, and in the five years prior to the war we exported the equivalent of two years' production. From 1873 to 1914 we exported about two thousand million tons. It seemed to him that this exportation must bring us appreciably nearer to the day when we should not have cheap coal. With regard to the decline in output per head, Prof. Louis looked to an increase in the production per head as the salvation of the situation. If there was increased production of coal as the result of more strenuous labour, and probably the introduction of better machinery, would not that react in producing a fall in prices? If that were the case he could not see how high wages were to be maintained. Could Prof. Louis give any data as to the corresponding output per head of those engaged in the coal industry in other countries? Prof. Louis also had referred to combines which would bring about considerable economies in administration. There were one or two directions other than those instanced by Prof. Louis in which combines would have advantages. If there were efficient combination and efficient management of pits over a considerable area it would be possible by means of electric distribution of power from central generating stations working on coal which had probably a very low market value, to operate the pits at a very greatly reduced cost and in that way economise on the 7% used at the collieries. It would favour the introduction of coal-cutting machinery which in many cases was electrically driven. In this way there would be the advantage of utilising this waste coal and obtaining a con-

siderable amount of by-products of very great value. Briquetting was one method of disposing of the low-class small fuel at depots, but such bituminous coal mixed with pitch would probably give a briquette which would not appeal to the ordinary consumer. In South Wales, where nearly all the briquetting was done in this country, 96% of the total amount of coal briquetted was steam coal, and was low in volatile matter. What was wanted was a really good briquetting agent other than pitch which was suitable to highly bituminous coals.

Mr. W. H. QUARRELL suggested that the figure for royalty given in the paper was rather on the high side. As regards materials we must not look for any reduction in the cost in the future, at any rate for several years. He would like particularly to mention the cost of waggons, which was an extremely serious thing. While the waggon trade was bound to have a period of great prosperity after the war, the waggons belonging to the private owner and to collieries were rapidly deteriorating. Moreover, we had yet to solve the problem of whether we were going to have 8, 10, 15, or 20-ton waggons. Then again tubs were a serious question. A great many were inclined to complain of the officials, but they must admit that the officials had been fairly lenient on this question of tubs and dust. The Clifton prosecution, which ended about 10 days previously, had enlightened them and was a caution. The difficulties, however, under present circumstances of getting tubs into the pits, and bringing them to the level in accordance with the statute, had not received quite sufficient justice. Prof. Louis had put down interest and profit at 8.65% and he had stated that this figure was for mines which had been successful. His own calculations related to certain concerns which had passed through many difficulties and which he could not say had been so successful, but taking into account a proper sinking fund the profit was under 5%. If it had not been for carrying on a trade upon which the country so much depended, the people with money in many colliery concerns would have been better off if they could have invested in War Loan. With regard to prices, it was not without interest to notice that whereas in the metropolis at the present time a good class coal could be obtained for 39s. 6d. and a good kitchen coal for 35s. 6d., the price of coal in Frankfurt was 53s. 4d. He had taken out from general statistics of the United Kingdom the comparative figures of production for 1897 and 1912 per annum per person employed at the pits. In the former year it was 298 tons and in 1912 it had fallen to 244 tons. That was a very serious drop. He admitted that in 1912 there was a coal strike and so probably the 244 tons would have to be taken as a little higher, but between those two years there were two very marked epochs. One was the Workmen's Compensation Acts and the other the Eight Hours Act. In the United States in the corresponding years the production per annum per person employed was 494 and 660 tons respectively, and to him these were most remarkable figures. As to co-operative working, anyone who had had anything to do with the working of collieries must be impressed with the difficulty of regularly procuring sufficient spares or of borrowing an article from your neighbour. Therefore it would be of enormous advantage to have central buying agencies for various districts in order to influence standardisation of the apparatus employed. A further feature for the successful future working of collieries was the working of the thin seam. That was a problem that had come forward with great seriousness. At a meeting on November 10th in Lancashire, a very experienced colliery manager, Mr. J. Jackson, said that in 1910, which was a

perfectly peaceful and normal year, he had put some of his best men on to a 2-ft. seam and the greatest output he could get was one ton per man per day. Mr. Jackson had said that it was his considered judgment that under present conditions, including the minimum wage, he would not venture to expect more than $\frac{1}{2}$ ton per man per day from such a seam. Another very important point was that the collieries of this country had very largely grown up by rule of thumb and by rough and ready methods of management and that they had not called in early enough the man of science.

Major G. E. MORGANS, R.E., suggested that one method of increasing output was to guarantee to the workmen that the rate which they had been promised should be maintained notwithstanding the greater output. The concurrent advantage to the colliery proprietor of the increased total output and resultant lowering of total cost per ton of coal landed was manifest. He thought that the realisation of this guarantee was one of the reasons why in America the output per man per shift was as high as it was, although the greater thickness of the seams was the main factor in the big output they got there. Our seams were relatively so very thin that it had not been possible to introduce the same simple coal-cutting machinery which was in vogue in America. It was not suitable to our older collieries.

With regard to the output from thin seams, Major Morgans stated that he had cut coal from thinner seams than 2 ft., and he could say that there were plenty of collieries working on thin seams which were getting very much larger outputs per man than had been mentioned by Mr. Quarrell.

Mr. WALTER F. REID, referring to the question of the thickness of seams, said that in the case of the St. Louis Exhibition there was a very thick seam, into which the railway wagons were lowered and loaded by the hewers underground. The coal was not touched afterwards, but crushed and burned under the boilers, and in the same way the ashes were removed mechanically. Long rows of these trucks were ready for this work and, moreover, they had a capacity more than double that of our trucks. The works which they served produced about half a million horse-power. It was a case in which the consumer and the miner worked together. The distance was certainly not very great, but it was not less than the distances found in our industrial areas in the north of England and the Midlands. Altogether, he thought there was a possibility of a better arrangement being made between the miner and the user. One method which had not been referred to was to gasify the coal in the lower part of the mine, in a producer, without bringing the coal to the surface for the purpose. He had suggested that before and knew that Prof. Louis would raise objections to it and say it was dangerous and that the Government would not allow it, but at the same time it was quite possible, from the scientific and practical point of view, to produce power at the bottom of the mine and send it along a wire instead of transporting a very great dead weight of coal in trucks and bringing the trucks back. That was enormously wasteful and the possibilities of what could be done in this direction were to be seen in the manner in which some of the London railways had been electrified, the power being transmitted from one large power house. As to briquettes, he thought it would be found that where lump coal could be had they would not prove remunerative, as they would have to be sold at a lower rate than the expense of briquetting would bear. He also mentioned the use of dust in central establishments not for briquetting but for obtaining by-products and power on the spot. Dust should be

utilised in a central position; it was simply nibbling at a very big thing if a lot of small installations were put up over the country for utilising small quantities of coal dust fuel. Indeed, he thought the whole problem of power would have to be solved somewhat on the lines he had mentioned at St. Louis, viz., pulverising the coal at the pits and using it mechanically under the boilers. This prevented waste during combustion and was a better way of utilising coal than having lump coal of different sizes and all sorts of differences in working conditions which the consumer was always grumbling at but could not control.

Mr. J. W. GORDON said that in the comparison which had been instituted between American and English costs there were certain discrepancies which he hoped it would be quite easy to put right. There was first the question of profit which appeared in the English statement but did not appear in the American statement, and then there was also the question of materials and administration. Prof. Louis had said that in this matter there was not so much difference between the English and American account, but looking at the figures there would seem to be a very considerable difference. In the English statement materials and administration appeared together as 16½%, whereas in the American statement materials alone came out to 17% and administration on top of that amounted to 10%, a total of 27% as against 16½% in the English statement. He did not know whether he had misapprehended the figures but it appeared to him a point that was worth clearing up. Prof. Louis had also stated that it was difficult to see how the cost of sea-borne coal was arrived at and that there was a difference of 5s. 3d. representing the profits of the various merchants through whose hands the coal passed, as well as waste and loss in carriage. The answer to this question appeared to be furnished by the estimate of the cost of bringing coal by rail into London at 9s. per ton. He took it that the cost of bringing it by rail must regulate the cost to the London purchaser for the reason that a very large proportion of our coal must be brought by rail. Thus the price of rail-borne coal must regulate the price of that coal which was brought by sea. In other words, the sea-borne coal must bear the price of rail-borne coal.

Mr. J. B. COWBURN said it seemed that a reduction in the price of coal must take place either by increasing the rate of output per man or by diminishing wages. He did not, however, recognise why it was necessary to disturb the whole of the labour market when the object could be achieved by legislation which would reduce the railway rate for carrying the coal to London. The conditions of mining underground were certainly not such as to induce the miner to want to work longer than necessary. He noticed that whereas wayleaves were 3d., royalties were 6d. The man who was paid the higher figure had the surface of his land left practically intact to do what he pleased with but the man over whose land wayleaves were obtained was deprived of the use of a certain amount of his land entirely. As to the suggestion that there should be combination among colliery owners, he quite realised that this might lead to administrative economies, but combines were generally looked upon as likely rather to force up prices than to decrease them.

Mr. NORMAN SWINDON said that what had happened in America with regard to increased output per man had been the development of a new system of management on scientific lines. This was the outcome of a number of very able researches on the part of Mr. Taylor, who had investigated the number of operations involved

and reduced them considerably and at the same time increased the output from 8 to 40 times according to conditions. He himself was engaged at the present time in working out bonuses and had found that it was possible to show a substantial decrease in costs, at the same time almost doubling the men's wages. The point to be borne in mind was that they must have the confidence of the men and that there would be no attempt to cut the rate merely because the men were earning high wages, otherwise the bonus system would be doomed to failure. It was purely a matter of careful analysis for the men to double their wages and the cost to be reduced by one-third. That was one of the reasons why the output in America was greater than it was in this country.

Prof. LOUIS, replying to the discussion, said that he hoped it would not be thought that he suggested that the workman alone was to blame. He considered the employer was at least as much to blame as the workman for the position in which we found ourselves to-day. At present, however, the workman had the upper hand, and it was better to commence the attack on that side, but it certainly was not his aim to suggest that the fault lies entirely with him. Mr. Cowburn had asked why royalties amounted to 6d. and wayleaves to 4d. That question implied a misconception of the difference between the two things: a royalty was a purchase of the coal, whereas a wayleave was merely an occupation rental, either above or below ground. An owner could only sell his coal once, whereas he could lease his land underground or above ground for an infinite period. The same speaker also suggested legislation to reduce the railway rate, but legislation could not reduce the cost of railway transport. It was impossible to cheapen things by legislation. Suppose as an extreme case that the country took over the railways and carried the coal for nothing, that would not reduce the cost of carriage. The country would pay for it, and the cost would come out of the nation's pocket. Such suggestions were based entirely on an economic fallacy. Prof. Brame and Mr. Gordon both wanted to know why the American colliery owner made no profit. He must confess that the table he had exhibited did rather suggest that, but the fact was that he had simply quoted figures which the American authorities had supplied; they did not suggest that the Americans made no profit, but simply that the profit was not disclosed. The percentages were simply the percentages of the cost of coal without taking profit into account and that was why they were somewhat higher relatively than the English figures. In reply to Mr. Gordon, he himself could see no discrepancy between the respective figures although the American ones were a little higher than the English for the reason he had given. Mr. Gordon also suggested that the reason why sea-borne coal apparently made a larger profit was because the price was based on the price of coal brought by rail. That was, on the surface, a quite obvious suggestion, but he himself had hesitated to put it forward because it seemed to him that if it were the case nobody would buy ex ship. People would buy f.o.b. and pay their own sea rates to the Thames if they used sufficiently large quantities. He had suggested there were other reasons which he did not know to account for the fact that the man who carried the coal by sea appeared to make 3s. more profit. There were, however, probably more wastage and losses by sea than by rail. In reply to Mr. Lupton and Mr. Quarrell, he should explain that he had been rather careful to confine the paper to the economics of coal production and to avoid technicalities because he did not think that was the right place for such considerations. As to Prof. Brame's

remarks upon briquetting, the bulk of the coal briquetted on the Continent was bituminous coal. It was perfectly suited for this purpose and made an excellent briquette for household and other uses. It was quite true that 90% of the coal briquetted in South Wales was steam coal, but the reason was not that bituminous coal was not suitable but that steam coal dust had practically no market value, whilst bituminous coal had, and that was why the former was briquetted. In the same way he did not agree with Mr. Reid that the profits on the sale of briquettes would be so small that the business would not be remunerative because the dust that was to be briquetted had so small a market value. There were accumulations of dust which were left simply because it could not be used as such, but he held that it would pay handsomely to briquette it. The suggestion that coal dust and fine coal might be used for power production had often been made, but it was one which bristled with difficulties. As far as he knew there had not yet been a producer made that would satisfactorily deal with dust. The problem was nowhere near satisfactory solution at the present moment. Mr. Reid had also suggested that it would be more satisfactory to generate electricity at the pit either underground or at the pit's mouth and transport electricity rather than coal. That was by no means an easy problem to deal with straight off. In fact, it could not be answered without knowing the conditions in each case. Electricity could not be transported for nothing: for every mile that the current was transmitted, the resistance dissipated a certain amount of current, so that a certain amount of the coal used in generating electricity at the pit's mouth was used in transporting the electricity to its destination, and it became a question of calculation whether it was cheaper to burn the coal there or to burn it in the locomotive for transporting the coal. Generally speaking, from one or two special cases which he had investigated, he much doubted whether it was cheaper to transmit electricity by wire for very long distances. For short distances it was cheaper, but somewhere between the two extremes there came a margin which was a matter of rather complicated calculation. He was exceedingly glad that Dr. Carpenter had struck what he thought was a high note and the proper note, viz., that it was every man's duty to do a fair day's work, and if that could only be impressed on the nation a very valuable piece of work would have been accomplished. How it was to be done otherwise than by education he did not see. One of the faults of the past century or more was that wages had been based on prices. The working man then said to himself that the less work he did the higher the price and the better his wages would be without his doing any more work. Surely the proper attitude was to base wages not upon prices but upon output. He admitted the question was a difficult one. Nobody had yet solved it and found the proper system and he admitted he did not see any solution as yet. At the same time he did not think the solution of the problem was beyond the wit of man. It should be possible to devise a system in which all the workmen in any industry would be interested in the results of that industry from the point of view of output, and the moment they found their interests were bound up with big outputs then the problem would be solved. Until that time, he confessed he did not see how we were going to get out of the difficulty which must be got out of if the best results were to be obtained from our coal-fields by producing coal at least as cheap as that of other nations. He was firmly convinced that it was the duty of everyone connected with the coal trade to use their utmost energies to attain that end.

Nottingham Section.

Meeting held at Nottingham on Wednesday,
November 14th, 1917.

DR. R. M. CAVEN IN THE CHAIR.

The CHAIRMAN gave an introductory address in which he briefly reviewed the history of the Society and referred to the large increase in its membership since the outbreak of war. The increase in membership of the Nottingham Section he attributed largely to the recent growth of chemical industry in the district.

DISCUSSION ON NITRE CAKE.

Mr. J. T. WOOD said that the method he had used to dissolve nitre cake was to place it on a perforated shelf in a rectangular slate tank having a capacity of about 16 cub. ft. The cake dissolved rapidly and the solution soon became saturated. He had used the solution for pickling skins and also for refining grease. For the former purpose it did not appear to have the same action as an equivalent quantity of sulphuric acid. He mentioned that the amounts of sulphuric acid found by titration in three different samples of nitre cake were 26.95, 30.4, and 27.34% respectively (the figure 31.56% had been mentioned in this J., 1917, 811). A saturated solution of the strongest of the three samples, made in the cold, had sp. gr. 1.4721 and showed sulphuric acid (by titration) 252.3 grms. per litre, total sulphates (as SO_4) 569.7 grms. The saturated solution appeared to extract further quantities of acid from nitre cake; thus, the relative acidities of the saturated solution when prepared and after three and sixteen hours' further contact with the cake were 10.4, 11.2, and 13.4 respectively.

Mr. WOOD concluded by referring to the principal papers on the subject which had appeared recently in the *Journal* (1915, 857, 1121; 1916, 77, 109, 155, 418, 486, 838, 1059, 1152; 1917, 336, 385, 575, 591, 810).

Mr. W. G. TIMMANS said that nitre cake when fresh was dry and easily handled, but it readily took up moisture from the atmosphere. Railway companies refused to supply wagons for conveyance; owners must supply wagons. The liquid dripping from a wagon of nitre cake, after transit in wet weather, was tested and found to contain 28% of free H_2SO_4 . A system of motor haulage had been organised in Nottingham for delivery to consumers. Workmen handling nitre cake should be provided with wooden clogs and have their clothing protected by sacking. Indiarubber gloves should be used for protection of the hands. Special dry storage should be provided in an isolated building, otherwise serious damage would occur. The free acid content of fresh dry nitre cake might vary from 19 to 28% in the same batch. Wood, stone, or slate tanks were being used; lead was not prohibited. Siphons should be used for decantation; taps or valves were useless. His firm made a solution containing 14–15% free H_2SO_4 which was sold under the name of sulphate acid. Much difficulty was experienced in storage and delivery to consumers owing to crystallisation of the sodium sulphate. The solubility of the crystals varied with the atmospheric temperature, and once formed they did not dissolve in the solution. Nitre cake was being used in the Nottingham district for lacc bleaching, grease extraction from wool, pickling of metals, and mineral water manufacture. Some

trouble had been caused in lace bleaching by discoloration of the goods, this had been overcome by increasing the free acid content of the bleach bath.

Mr. G. C. GRISLEY said that probably the most successful method so far employed for utilising nitre cake was in the production of saltcake and hydrochloric acid by furnacing with salt in an ordinary saltcake pot and furnace. The products so obtained were never up to the standard of those made from salt and acid direct; the salt cake generally showed a tendency to cake, and it was very difficult to get successive charges down to the minimum of free acid and salt owing to the differences in acid strength of even the same batch of nitre cake. The hydrochloric acid obtained occasionally contained nitrous gases due to the incomplete decomposition of nitre. These were very troublesome in the handling of the acid, many serious accidents having been recorded both in filling and emptying carboys. Nitre cake had been used in the manufacture of crude ferric sulphate for sewage precipitation, by furnacing with burnt ore from pyrites burners, grinding, and leaching with water. It had also been used as a carrier for sulphuric acid for export, by making a cake containing up to 60% sulphuric acid and running it into drums of sheet steel, so obviating the expense of following Board of Trade regulations. It could also be used as a diluent for sulphuric acid in the manufacture of superphosphate, and an acid works attached to such an industry could easily dispose of the whole production of nitre cake obtained in the manufacture of the acid. Acid containing 24 to 3% of Na_2SO_4 could be easily handled and without deleterious effect on the superphosphate product.

Mr. JOHN WHITE said that unless adequate precautions were taken it might happen that carbon dioxide produced with the use of nitre cake for use in aerating mineral waters, might cause the mineral water to be contaminated with arsenic or with nitrous compounds. Some efficient process for washing the gas before use would be necessary.

Mr. TIMMANS replied that some trouble had been experienced in mineral water manufacture, but it had been overcome by washing the carbon dioxide with sodium bicarbonate solution.

Dr. TERLINCK said he had many years ago used nitre cake as a substitute for sulphuric acid for the recovery of fats in the wash waters of wool in a factory, where it did not pay to recover subsequently the potassium salts. He used the nitre cake in big lumps, placing them on a pitch pine lattice at the top of a vat. The crystals of sodium sulphate eventually formed gave no trouble if the usual cork were replaced by a wooden plug, some 6 inches in diameter and as high as the vat itself. The plug could be removed by pulling from the top by means of a chain. The running off of the solution and eventually the centrifuging of the sulphate crystals was quite simple. He thought, however, that the applications of nitre cake hitherto suggested were not sufficient to cover the production, and he therefore proposed to use this troublesome by-product for the purification of ammonium salts. He foresaw that in the rather near future synthetic ammonia would become a dangerous competitor to coal-ammonia if steps were not taken to remove the organic bases contained in the latter. Already before the war, specially purified ammonium sulphate (e.g., the brand *Gas de Paris*) was at a premium on the Continental fertiliser market. Only purified ammonia could, as he had heard from different sources, be used for catalytic oxidation to nitric acid, etc. He had himself devised, years ago, a method for the preparation on a small scale of pure ammonia and its derivatives, his purpose having been to overcome the usual difficulties in the ignition

of magnesium ammonium phosphate in the course of phosphate estimations. After having ascertained that the treatment with nitric acid, as suggested by Stas, was not very efficient (probably because the acid distilled over before it had done its work), he had obtained very good results by heating commercial ammonium sulphate with sulphuric acid and eventually with nitre cake, in the presence of mercuric sulphate. The method was a development of the Kjeldahl process and required exactly the same precautions; in recent years, copper sulphate had replaced the expensive mercuric catalyst, and he thought the method could be applied industrially. The ammonia could be received directly in a solution of nitre cake and the product heated as above described. Out of the mixture of sodium, ammonium, and copper sulphates obtained the copper could be easily recovered by means of sodium sulphide. Instead of lime, ignited magnesite could be used to expel the ammonia and the solution of sodium and magnesium sulphates thus obtained could easily be freed from iron by means of hypochlorite, and subsequent addition of sodium carbonate should precipitate magnesium carbonate, sodium sulphate being left in solution. According to the proportions, temperature, concentration, etc., it was possible to produce the different varieties of magnesium carbonate, from crystallised $MgCO_3$ to basic $MgCO_3 \cdot (MgO + xH_2O)$. As a consequence, the different qualities of magnesium oxide could also be obtained, covering the demand for medical purposes, for basic magnesia cements, marmorites, lithoxylates, etc., and also for some specialities for the steel industry. He thought it worth while to examine if even ignited dolomite in one or another of its stages of de-carbonation could not be used instead of magnesite. Concur, in an unpublished investigation of the behaviour of ignited dolomite towards hot ammonium chloride solutions, had ascertained that no lime was dissolved so long as any magnesia was present; he thought it would not be impossible to work out a similar process in the case of sodium and ammonium sulphates, though evidently the presence of the Na and SO_4 ions complicated matters somewhat. He pointed out that if investigations in this line proved successful, the demands of English industries for magnesium compounds could be covered by home production, thus removing its dependency upon the Greek and Stassfurt deposits. In conclusion he alluded to the fact that Great Britain years ago had led the production of magnesium compounds and quoted some expressions and uses still existing on the Continent as a result of this bygone state of affairs.

Dr. E. NAEF said that the suggestions for the use of nitre cake which had been advanced all dealt with the utilisation of the so-called free acid in the nitre cake. Important as that problem was, especially at the present juncture when sulphuric acid was difficult to obtain, it did not solve the problem of nitre cake, which was produced in millions of tons, the bulk consisting of sodium sulphate which had to be worked up and converted into marketable articles at a profit. From a great many experiments which he had carried out, it appeared that one way of dealing with it was to convert the nitre cake or sodium sulphate into sodium sulphide. On grinding nitre cake or sodium sulphate with finely ground anthracite, charcoal, or boiler coal and heating to a comparatively low temperature, say 500° — 600° C. or more, in an iron vessel or furnace, sodium sulphide was obtained with a yield of 95—98%. When nitre cake was used sulphur dioxide was evolved at the same time. This could be avoided if the free acid was neutralised in the grinding mill with soda ash. The sulphurous acid evolved could be used as such

or in the production of sulphites or bisulphites, or for neutralising ammonia liquors, such as gas liquors, making ammonium sulphite, and also in a limited degree for making acetic anhydride. Liquid sulphur dioxide had also been used of late in the extraction of hydrocarbons and bituminous coal. As the process must be arranged so as to work on a large scale, success depended on constructing a plant which dealt more or less automatically with the charge and discharge of materials. Sodium sulphide thus obtained could be refined by crystallising and commanded a very fair market price. It was used for chemical and metallurgical purposes. The production of sulphur dyes had also assumed great proportions and about 50,000 tons of sodium sulphide crystals per year was required for this alone. It was also possible that by treating sodium sulphide at higher temperatures with a limited amount of air it could be re-oxidised to sodium sulphite directly. Sodium sulphite could now be converted into sodium carbonate by treating it with carbon dioxide or flue gases and water vapour at temperatures ranging from 300° to 500° C. in iron vessels, possibly in the same vessel where the reduction has taken place. The mass was kept well stirred so as to ensure the intimate contact of gas and solid. The vessel should be so arranged as to have automatic feed and discharge of material and counter-current gas system. Hydrogen sulphide evolved could be used for sulphur recovery by the Chance process. In treating sodium sulphide with hydrogen at temperatures from 360° — 600° C. a large amount of hydrogen sulphide was given off, but he had not succeeded at that low temperature in converting it into sodium or sodium hydride. The product obtained dissolved in water and gave a strong caustic soda liquor which still contained some sodium sulphide. Treatment with milk of lime and decantation gave stronger caustic soda liquor. In place of hydrogen, producer- or water-gas could be used, but the carbon dioxide content of these gases converted the sodium sulphide into sodium carbonate. As regards the utilisation of acid in nitre cake, he had found that by treating nitre cake heated to 300° — 350° C. with superheated steam of 300° C., dilute sulphuric acid distilled off. The strength of this acid was about 10—15% according to the quantity of steam used. The beginning of the distillation gave more concentrated acid than the end as the charge became exhausted. This acid was too weak to be concentrated. A small amount of sodium sulphate, 1—2%, was also carried over with the water vapour. The amount of sulphuric acid driven off was 90% of the acid contained in nitre cake, so-called free acid, when operating with nitre cake containing 27—30%. The utilisation of nitre cake seemed to him to be bound up with the alkali industry, as the sodium salts produced as stated above could be refined in works of that nature most profitably.

Dr. E. B. R. PRIDEAUX said that in view of the well-known solubility relations of $Na_2SO_4 \cdot 10H_2O$, which seemed to retain its general form in the presence of moderate amounts of sulphuric acid, the best separation of the sodium sulphate from sulphuric acid would appear to be effected by the cold water percolation as described by Mr. Wood, the temperature being kept as low as possible. On the other hand if some method of steaming with subsequent separation of hot liquid were used, the temperature should be as high as possible, since the solubility of the anhydrous salt diminished with rise of temperature from 32° to 100° C. The first-named temperature would be the worst from this point of view, as the solubility was then at a maximum. With regard to distillation with superheated steam, it was to be noted that the solubility in water fell to zero at a temperature above 360° C.

Communication.

NEW RESEARCHES ON THE VARIABILITY OF PLANTATION PARA RUBBER.

BY B. J. EATON, F.I.C., GOVERNMENT AGRICULTURAL CHEMIST, FEDERATED MALAY STATES.

The present communication summarises the principal and most important new results obtained by the author since the publication of the previous papers by himself together with J. Grantham and F. W. F. Day (*vide* this Journal, October 15, 1915; July 15, 1916; October 31, 1916, and January 15, 1917). Although these new results neither add to nor subtract from the theories enunciated in the previous papers as to the cause of variability, they deal with interesting and important side issues and contributory factors which influence the rate of cure or speed of vulcanisation of plantation Para rubber, and thus add confirmation, if any were needed, to the results given in the previous papers and the theories deduced from these results. No special sequence has been adopted in describing these experiments.

One reason why comparatively slow progress has been made in these investigations in the author's laboratory is that, in order to prove any one particular fact, nearly every experiment has been repeated on ten different dates, in order to eliminate any errors or the influence of secondary factors.

The work has, however, now reached such a stage that this is no longer necessary, since methods of preparation, with the advance in knowledge gained from the hundreds of samples already examined, can now be sufficiently rigidly controlled, so that identical results are obtained from any one method of preparation, provided sufficient care is taken to eliminate any secondary factor. The only cases in which it may be necessary to repeat an experiment on a special method of treatment or preparation of the raw rubber, is where such method has only a slight influence in either accelerating or retarding the rate of vulcanisation. In such cases, the differences obtained are naturally of academic or scientific rather than of practical importance, although the results obtained may lead to other important results in practice.

It is proposed here merely to give brief details of each experiment with the results obtained in respect to rate of cure, together with the cause responsible for increase or decrease in rate of cure, in the light of the theories already advanced.

The figures showing tensile properties are omitted, since they do not give any differences of particular interest. The complete figures will, however, be published in a special bulletin which is being compiled, giving full details of all the experimental research which has been carried out during the last three years in the Experimental Vulcanising Factory and Rubber Testing Laboratory of the Department of Agriculture, Federated Malay States.

Rolling up of wet sheet.

A note on this experiment, which had at the time just been carried out, was added at the end of a previous communication (this J., July 15, 1916). The following is the result of one comparative test which was confirmed by other experiments. Unsmoked sheets of average thickness (plain, *i.e.*, not marked by grooved rollers) were prepared, each from 1 gallon of latex diluted to contain 1.5 lb. of dry rubber per gallon, coagulated by the addition of 3 oz. of a 5% solution of acetic acid. The control sheet was hung to dry in the ordinary manner and the other sheet,

immediately it was taken from the sheeting machine, was rolled by hand into a cylinder. Both the control and the cylindrically rolled sheet were creped when the former was dry. (N.B.—A period of six to seven days after coagulation, before machining to thin crepe, is actually sufficient for all types of rubber.)

The results shown in Table I were obtained, "A" being the rolled up sheet and "B" the control sheet hung to dry in the ordinary way.

TABLE I.

Ref. No.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
	Hours.	Hours.
208 S.2 A.	1½	1½
208 S.2 B.	2½	2½

The experiment was repeated on ten different dates with similar results.

The above results show that by rolling up wet sheet, the cure becomes nearly as rapid as in the case of "slab" rubber, *i.e.*, unpressed or lightly pressed coagulum, containing practically all the serum, except that which drains out during the preliminary contraction.

This shows that the principal factor affecting the rate of cure of "slab" rubber is the amount of water left in the coagulum and that sufficient nitrogenous matter is left in sheet of average thickness to produce a rapid rate of cure, provided the moisture is retained for a period of six days or longer, so that the nitrogenous matter can become decomposed and produce the degradation product responsible for acceleration in rate of cure.

Influence of different thicknesses of sheet when rolled up wet.

More recent experiments on "slab," rolled-up thin wet slab, rolled-up thick wet sheet, and rolled-up thin wet sheet, together with controls, show that the thickness makes a slight difference but that the primary factor is moisture content. The following are the results from one experiment which was confirmed by all subsequent experiments:—

TABLE 2.

Ref. No.	Type of rubber.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
		Hours.	Hours.
297 S.1 A.	Slab.	1½	1½
297 S.1 B.	Rolled thin slab.	1½	1½
297 S.1 C.	Thin slab.	1½	1½
297 S.1 D.	Rolled thick sheet.	1½	1½
297 S.1 E.	Thick sheet.	1½	1½
297 S.1 F.	Rolled thin sheet.	1½	1½
297 S.1 G.	Thin sheet.	2½	2½

The reason why the rolled-up thick and thin sheet does not cure quite as fast as the slab is undoubtedly due to the removal of the second accelerator, *i.e.*, the accelerator present in the serum and latex, which is removed by the rolling or pressing on the sheeting machines.

Thin v. thick layers of coagulum.

A further experiment, which shows that the rate of cure is influenced by the amount of moisture retained, was as follows:—A gallon of latex of sp. gr. 0.9910, corresponding to 1.5 lb. of dry rubber per gallon of latex, was coagulated by the

addition of 3 oz. of a 5% solution of acetic acid in the ordinary narrow enamelled pans, 18 in. long by 6 in. broad by 3½ in. deep. A similar quantity, coagulated in a similar manner, was distributed, before coagulation took place, *i.e.*, immediately after the acid was added, between ten broad pans, so that each pan contained only a thin layer of latex. On the following day, the coagulum was rolled by means of a hand wooden rolling-pin and approximately the same amount of serum removed from each, *i.e.*, (a) from the thick coagulum, and (b) from the ten thin layers of latex combined. The serum in the pans, produced by the contraction of the coagulum, and the serum which drained out of the coagulum for several hours after rolling was also included and thus the total serum removed from the coagulum by drainage and rolling was obtained. The rubber was crêped after a period of about 12–14 days, the ten layers of thin coagulum being combined and crêped together.

The results of one experiment are given in Table 3:—

TABLE 3.

Ref. No.	Type of rubber.	Serum removed by drainage and rolling.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
			Hours.	Hours.
189 S.7 A.	Thick coagulum.	92 oz.	1½	1½
189 S.7 B.	Thin layers.	81 oz.	2½	2½

It will be seen that although the quantity of serum removed in each case is very similar, the "slab" rubber or thick coagulum cures much more rapidly than the thin layers. In the light of previous experiments, the acceleration is obviously due to the decomposition of the nitrogenous substances in the thick coagulum owing to the moisture present, while the thin layers are practically dry in two days and thus degradation of the nitrogenous matter and formation of the accelerating agent is inhibited. It will be observed, however, that these thin layers cure more rapidly than ordinary thicker sheet rubber made from thick coagulum, and this is due almost certainly to the second factor which the author has found to exist in latex and to be responsible for acceleration in rate of cure, *i.e.*, the substance (the composition of which is at present unknown) which exists already formed in the latex and serum. These thin layers retain a much larger proportion of the serum than ordinary sheet rolled out from thick coagulum. This experiment is of considerable interest from the point of view of estate practice, since in the preparation of sheet rubber of any definite thickness, the original thickness of the coagulum, up to a certain point, will have an influence on the rate of cure.

The rate of drying (*vide* later experiments) and hence the rate of cure is also affected by the toughness or hardness of the sheet, which is influenced by the amount of rolling, and this factor therefore enters into the problem in connection with the original thickness of the coagulum and the final thickness of the sheet.

Influence of rate of drying on rate of cure.

Although the above experiments show that the rate of drying has a marked influence on the rate of vulcanisation, it was considered advisable to carry out further experiments in which the rate of drying of different types of rubber was determined daily, till the samples were as dry as they would become under ordinary air-drying conditions.

The results obtained are given in Table 4 below:—

TABLE 4.

Ref. No.	Type of rubber.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
		Hours.	Hours.
251 A. . .	Unpressed slab.	1½—1½	1½
251 B. . .	Pressed slab.	1½—1½	1½
251 C. . .	Thick plain sheet.	2½	2½
251 D. . .	Thin plain sheet.	2½	2½
251 E. . .	Thick crêpe.	2½	2½
251 F. . .	Thin crêpe.	3	3½

Table 5 shows the percentages of moisture in the above samples for a period of 15 days.

TABLE 5.

	A.	B.	C.	D.	E.	F.
Immediately after machining	64.5	61.0	23.9	22.7	22.5	17.4
3 p.m. same day (<i>i.e.</i> 5 hours later)	—	—	14.3	14.1	12.4	6.2
1 day after	56.1	55.9	9.9	9.3	9.1	2.2
2 days after	52.6	53.3	8.7	8.0	6.9	0.0
3 days after	47.1	48.1	7.9	7.3	5.7	0.2
4 days after	44.9	45.2	7.4	6.8	5.0	0.4
5 days after	42.6	43.2	6.9	6.3	4.5	0.3
6 days after	36.4	37.5	6.3	5.8	3.5	0.1
7 days after	29.2	31.0	6.0	5.4	2.7	0.2
8 days after	22.6	24.1	5.5	4.9	2.2	—
9 days after	21.7	22.2	5.4	4.6	1.7	—
10 days after	21.4	21.7	5.1	4.3	1.4	—
11 days after	21.4	21.8	4.9	3.9	1.1	—
12 days after	21.4	21.7	4.9	3.9	1.1	—
13 days after	21.2	21.6	4.6	3.6	0.7	—
14 days after	21.1	21.5	4.4	3.5	0.4	—
15 days after	21.1	21.5	4.3	3.3	0.6	—

It will be seen from the above results that the rate of curing is influenced by the rate of drying and, under ordinary circumstances, the amount of moisture during the first six days of drying alone influences the rate of cure. Later experiments will show that under the normal conditions of shade temperature (about 85° F.) in this country, any type of raw rubber can be converted into thin crêpe about six or seven days after coagulation and rolling.

A further and more complete experiment, the results of which are given in Table 6, confirms the above results:—

TABLE 6.

Ref. No.	Type of rubber.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
		Hours.	Hours.
272 A. . .	Unpressed slab.	1	1
272 B. . .	Pressed slab.	1	1
272 C. . .	Thick sheet.	1½—2	1½
272 D. . .	Thin sheet.	2	2
272 E. . .	Thin sheet rolled.	1½	1½

6 days after	26.3	26.3	4.8	3.8	12.7	2.3	0.1	9.9	15.9
7 days after	22.7	22.3	4.7	3.5	12.6	1.8	0.1	9.4	14.7
8 days after	22.0	21.7	4.5	3.2	12.5	1.5	0.1	9.0	14.4
9 days after	21.7	21.4	4.4	3.1	12.4	1.4	0.1	8.7	14.0
10 days after	21.7	21.2	4.1	2.8	12.3	0.9	0.0	8.3	13.8

The above results confirm the previous experiment (Ref. No. 251) and contain results of further interest which need discussion. It will be seen, in both cases, that unpressed slab, *i.e.*, coagulum removed from the coagulating pans and placed directly on the drying racks, does not cure faster than pressed slab, from which a certain amount of serum has been removed by rolling with a wooden hand-rolling pin. The reason for this is obvious when the figures for rate of drying are considered. It will be seen that, during a period of 10 days in each case, the pressed slab does not lose its moisture more rapidly than the unpressed slab although it has less moisture immediately after rolling, and this is due to the fact that the compression of the slab by hand rolling toughens the rubber somewhat and prevents it from drying rapidly. In both cases there is sufficient moisture to produce the maximum amount of accelerating substance under the conditions employed.

This experiment, with pressed and unpressed slab, was repeated in a separate experiment on ten different dates with similar results. It is unnecessary, however, to give the results in this paper.

The acceleration of cure of the rolled thin sheet compared with the thin sheet (as in Ref. No. 208, given previously), due to the retention of moisture, is apparent. The slight acceleration of cure of the thick sheet compared with the thinner sheet is also seen. It would appear, in this case, that the greater rate of cure is almost entirely due to the retention of a larger amount of the serum accelerating substance in the thicker sheet, since the rates of drying are very similar. This is also borne out by the slower rate of cure of the thick crêpe sample (F), which, although it starts with a higher moisture content than the thin sheet (D), has a slower rate of cure, due to losing its moisture more rapidly.

In manufacturing even thick crêpe, the washing water used is able to remove more of the serum, due to the tearing up and stretching of the rubber, than in the rolling of sheet between smooth even-speed rollers. The higher original moisture content of the thick crêpe (F) compared with the thin sheet (D) is due partly to the water which remains on the corrugated surface of the former.

It will be seen, by comparing samples G and H, that the blanketing of thin wet crêpe also accelerates the rate of cure slightly, whereas the rolling up of the thin crêpe into a cylinder (J) has no effect. (*Vide* Ref. No. 346, quoted later.)

Further detailed experiments on this latter point have been carried out, with similar effects, in the case of the blanketed thin wet crêpe, but the results need not be included here. In the case of the rolled-up wet thin crêpe, slight acceleration is sometimes produced and at other times the effect is nil. It is necessary, however, to seek a reason for the acceleration in rate of cure of the blanketed thin wet crêpe and the small or nil effect in the case of rolling up thin wet crêpe (although the rolling up of thin wet sheet into a cylinder has been shown to have a marked effect in accelerating the rate

of cure). In the light of previous experiments and from the results which accrue when thin wet crêpe is rolled up in this manner, several reasons may be deduced to explain this apparent anomaly although it will be difficult to ascertain which is really the correct cause (*vide* Ref. Nos. 340 and 346 quoted later.)

In the first place, when wet crêpe is rolled up in this manner, a great development of the growth of spores of micro-organisms, present in the rubber, takes place, with the formation of numerous pigments. When thin wet crêpe is blanketed, this only takes place to a comparatively small extent. When wet sheet is rolled up in this way, no formation of pigments takes place. When wet sheet is rolled, the cylinder formed is solid and no air is occluded, except such as is absorbed in the water present. This also applies to "slab" rubber or unpressed coagulum. When thin wet crêpe, which has a corrugated surface—even when finished on smooth rollers—is rolled up, the cylinder formed is full of air spaces, and the development of the micro-organism spores and the formation of pigment would therefore appear to take place only in the presence of air or oxygen. It is probable that these organisms either carry the degradation of the organic nitrogenous matter too far or else utilise the degradation products for their growth and the formation of pigment, and consequently no acceleration in rate of cure is produced when thin wet crêpe is rolled up in this manner. Another explanation may be that the conditions existing in the thin wet crêpe, rolled up in this manner, are aerobic, whereas in slab, rolled-up sheet, and blanketed crêpe, the conditions are anaërobic and the changes produced in the organic nitrogenous substances, resulting in the formation of a vulcanisation accelerator, are produced under anaërobic conditions. Which of these two explanations is correct remains to be proved. The correct explanation of this anomaly will be seen from the results in some more recent experiments quoted later (*vide* Ref. Nos. 346 and 340.)

The author is carrying out further researches on this point, in connection with the development of chromogenic organisms in dry raw rubber allowed to become damp or wet (*vide* Agricultural Bulletin, F.M.S., Vol. IV., Nos. 6 and 7, February and March, 1917).

Another interesting fact in connection with rate of drying and rate of cure is also presented in the above experiment (Ref. No. 272) and has been confirmed by subsequent experiments. It will be observed that although the sample of original thick crêpe (F) contains more moisture at the start than the blanketed thin wet crêpe (H), the percentage has dropped to 7.59 in the former case, one day after machining, while in the latter it is 15.57 and subsequent days show similar relationships. The reason for this is again obvious to those acquainted with the nature of the raw wet coagulum. The original thick crêpe is spongy and porous and loses its moisture comparatively rapidly, whereas a thin crêpe which has been subjected to the maximum of rolling with tight

rollers and is subsequently converted to blanket crêpe by rolling several thin layers together, is very tough and impervious and loses moisture very slowly. The rate of drying depends very largely on the amount of rolling, other factors, such as thickness, being constant. In spite of this slower rate of drying of the blanketed thin wet crêpe, however, it cures more slowly than the original thick crêpe or than the thick or thin sheets, which also dry more rapidly. This apparent anomaly is again explained by the practically complete removal of all the serum from the thin crêpe during washing and machining.

Effect of concentration of latex.

As would be expected in the light of the theories advanced by the author and his collaborators, the concentration of the latex has an influence on the rate of cure, the more concentrated the latex, *cæteris paribus*, the more rapid the rate of cure. This factor is responsible on estates for some of the variability in rate of cure, which occurs in the case of marketed rubber and is especially noticeable during the last year or so, in the case of "first latex" crêpe rubber. Formerly it was customary, in the case of the preparation of both sheet and crêpe, to dilute the latex, whereas more recently "first latex" crêpe rubber is manufactured by the coagulation of the concentrated latex, which may contain from 2.5 to 3.5 or even 4 lb. of dry rubber per gallon. In the case of sheet rubber, the pure latex from the field is diluted usually to contain from 1 to 1½ lb. of dry rubber per gallon, in order to obtain a sheet of good appearance. If concentrated latex is used in sheet manufacture, the coagulum is tough and difficult to roll and mark on the marking machines, and frequently contains bubbles due to fermentation, or bubbles formed when the coagulant is stirred and mixed with the latex, which are unable to escape owing to the thick nature of the latex. Needless to say, such bubbles have no deteriorating effect on the real quality of the rubber, and, from the point of view of real quality, sheet from concentrated latex is, *cæteris paribus*, of superior quality to sheet from diluted latex, and has a more rapid rate of cure, which is preferable from the manufacturers' standpoint. It is essential, however, in order to obtain uniformity in this respect, to adopt some standard dilution, but, if raw plantation rubber were sold on its real merits, the concentration of latex used should be as high as possible, to suit all estates, certainly higher than 1½ lb. of dry rubber per gallon.

Table 8 gives the results of experiments on two series of samples.

TABLE 8.

Ref. No.	Type of rubber.	Concentration of latex per gallon.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
		lb. oz.	Hours.	Hours.
212 S.1 A.	Slab.	1 14	11	11
212 S.1 B.	Slab.	1 4	11—11	11
212 S.1 C.	Sheet.	1 14	21—21	21
212 S.1 D.	Sheet.	1 4	21	31
212 S.1 E.	Crêpe.	1 14	3	31
212 S.1 F.	Crêpe.	1 4	31	31
212 S.6 A.	Slab.	2 5	1—11	11
212 S.6 B.	Slab.	1 5	11	11
212 S.6 C.	Sheet.	2 5	21	21
212 S.6 D.	Sheet.	1 5	21	21
212 S.6 E.	Crêpe.	2 5	21—3	3
212 S.6 F.	Crêpe.	1 5	31	31

Samples from highly concentrated latex from several estates have given greater differences than are shown in the table above. Later experiments, in which the author was able to obtain a much

more concentrated latex (about 3.5 lb. of dry rubber per gallon) have given even more marked results.

Progressive increase in rate of cure of sheet crêped daily.

Our experiments, described in previous papers, have demonstrated that a progressive change takes place in slab rubber or unpressed or lightly pressed coagulum during the first six days of drying or maturation, after which little or no further change takes place.

Similar experiments, in which comparative samples of sheet were crêped daily, up to the tenth day after coagulation, have given similar results.

The following are the samples prepared:—Ref. No. 254 A. Coagulum machined to thin crêpe same day. B. Converted to sheet and crêped 1 day after. C. 2 days after. D. 3. E. 4. F. 5. G. 6. H. 7. J. 8. K. 9. L. 10 days after. Table 9 gives the vulcanisation results.

TABLE 9.

254 K. ..	21—21	21
254 L. ..	21—21	21

This experiment (together with previous experiments on slab) shows that any type of rubber can be converted to thin crêpe, after about the sixth day, without affecting its quality or rate of vulcanisation.

The effect of smoking rubber.

In previous papers, the author has demonstrated that the smoking of wet rubber, as normally practiced on estates, in the preparation of smoked sheet for the market, retards the rate of cure, and that the retardation is due probably entirely to antiseptic constituents of the smoke employed. It has also been found that, while smoking invariably retards the rate of cure of "slab" rubber, in the case of sheet, comparative samples of smoked sheet sometimes cures faster than unsmoked sheet. A reason for this had to be sought and the effect was found to be due to a cause which the author had anticipated from previous researches, viz., the effect of heat. In the smoking process, two factors are involved, viz., the effect of the smoke products and the effect of the higher temperature. It has been found that the effect of the higher temperature of the smoke-house is to accelerate the rate of cure, by accelerating the biological changes which take place in the wet rubber during the first few days of drying. This explains why smoked sheet sometimes cures faster than unsmoked sheet, but is usually slower, owing to the retarding effect produced by the smoke products.

(Note.—In connection with vulcanisation researches carried out by the Imperial Institute on behalf of Ceylon, it is stated that smoking retards the rate of cure to a marked extent. This is possibly due to the type of fuel used in smoke-houses in Ceylon, or to some other factor. The author has reason to believe that the type of fuel is of some importance and that coconut husks, for instance, which give a dense smoke rich in creosotic products, probably produce a slower curing rubber.)

Sheet dried in hot air.

The following samples were prepared in order to ascertain the effect of the temperature of drying on the rate of vulcanisation, in the case of sheet rubbers :—

Ref. No. 330 A. Sheet, air-dried at ordinary temperature.
Ref. No. 330 B. Sheet, dried in hot air chamber at about 150°F.
Ref. No. 330 C. Sheet, smoked.

Table 10 gives the vulcanisation results for one series of this experiment.

TABLE 10.

Ref. No.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
	Hours.	Hours.
330 S.1 A.	2½	2½
330 S.1 B.	2	2
330 S.1 C.	2	2

It will be seen that the sheet dried in hot air vulcanises faster than the sheet dried at ordinary temperature. In this experiment, throughout the ten series, the smoked sheet also cured faster than the unsmoked sheet, which showed that the temperature effect in the smoke-house was greater than any retarding effect due to the smoking. The sheet dried in hot air was dried in a special wooden-walled chamber with steam coils at the bottom, over which the air was drawn by means of an exhaust fan. The waste steam from the boiler used for the vulcanisation machinery was employed, and, except for the steam left in the boiler, after work ceased at 2—3 p.m. daily, the chamber was only heated from about 9 a.m. to 3 p.m., although the temperature was maintained above the ordinary atmospheric temperature for a considerable part of the night, by the waste steam.

Slabs dried in hot air.

Similar experiments were carried out by drying slab rubber in hot air. The following samples were prepared :—

Ref. No. 319 A. Slab control, air-dried for 12 days.
Ref. No. 319 B. Slab smoked for 12 days.
Ref. No. 319 C. Slab smoked after air-drying for 7 days.
Ref. No. 319 D. Slab smoked after air-drying for 12 days.
Ref. No. 319 E. Slab dried in hot air chamber for 12 days.
Ref. No. 319 F. Slab dried in hot air chamber after ordinary air-drying for 7 days.
Ref. No. 319 G. Slab dried in hot air chamber, after ordinary air-drying for 12 days.

Samples C and F were left in the smoke house and hot air-drier for a further 6 days respectively and samples D and G for 12 days, after the original period of drying at ordinary temperature.

Table 11 gives the results of one series of the above experiment, which was repeated on ten different dates with similar results.

TABLE 11.

Ref. No.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
	Hours.	Hours.
319 S.4 A.	1 — 1½	1
319 S.4 B.	1½ — 1¾	1½
319 S.4 C.	1 — 1½	1½
319 S.4 D.	1	1
319 S.4 E.	¾	1
319 S.4 F.	¾ — 1	1
319 S.4 G.	1	1½

The most marked feature of the above results is the retardation in rate of cure of the smoked slab (B) and the acceleration in rate of cure of the slabs dried in hot air (E).

Another feature, which is observed, is that, after drying at ordinary temperatures for 7 and 12 days and then smoking (samples C and D), the rate

of cure is no longer retarded, in fact it is slightly accelerated, due almost certainly to the fact that the smoke has no longer any effect in retarding the cure, since it is not absorbed to any extent, while the heat of the smoke-house accelerates the cure. Similarly drying in hot air for a further period, after ordinary air-drying (samples F and G), accelerates the rate of cure.

Another interesting feature is the moisture content of the slabs after the different treatments, all samples being weighed on the same date. Table 12 gives the moisture content of the samples referred to in the table above.

TABLE 12.

Ref. No.	Moisture (%).
319 S.4 A.	28.1
319 S.4 B.	7.7
319 S.4 C.	24.3
319 S.4 D.	28.1
319 S.4 E.	15.3
319 S.4 F.	25.0
319 S.4 G.	28.3

It will be seen how remarkably rapidly the smoked slab (B) dries compared with the others; the next rapid, in this respect, is the sample dried in hot air (E). The samples which are smoked and dried in hot air, respectively (C and F), after maturing for 7 days at ordinary temperature, only lose a further small percentage of moisture, while those treated similarly after 12 days' ordinary air-drying (D and G) do not appear to lose further moisture. This is due to the formation of an impervious outer layer on the slab. Whether the greater rapidity of drying of the smoked slab (B) compared with the slab dried in hot air (E) is connected with the smoke products, it is not possible yet to say, as the conditions in respect of temperature, apart from smoking, were not strictly comparative.

Another interesting feature of the smoked slabs (B) was the fact that, on removal from the smoke-house, they sweated considerably and absorbed a small percentage of moisture. This may be due to the concentration of serum salts on the surface, the residual serum-products, obtained by the evaporation of latex serum, being very hygroscopic.

The fact that the smoking of sheet rubber sometimes accelerates and sometimes retards the rate of cure of the rubber, while, in the case of slab, the smoking process always causes retardation, is probably to be explained on the ground that slab contains much moisture and is very porous and soft, and thus the antiseptic smoke products are absorbed and affect the curing capacity of the rubber, before the heat has had time to accelerate the biological changes resulting in acceleration in rate of cure. In the case of sheet, which is much tougher and harder, and contains less moisture, due to rolling out of the coagulum, sometimes the heat and sometimes the smoke products affect the rubber first and determine its rate of cure.

Accelerated maturation of slab by drying in hot air.

In the above experiments (Ref. No. 319), it is seen that by drying or maturing slab or sheet rubber in a hot air chamber, the rate of cure is accelerated. It has also been shown in previous publications from this laboratory that the ordinary period of maturation of slab (and sheet) at shade temperatures (85°F.) is about six days. From the above experiments with slab dried in hot air, it was thought that the same acceleration in rate of cure, as is obtained normally in six days, might be obtained in a shorter period, by drying and maturing slab at a higher temperature; this

proved to be the case, as is shown in Table 13 below for samples prepared as follows:—

Ref. No. 332 A1. Slab dried in hot air 1 day, then crêped.
 Ref. No. 332 B. Slab air-dried 2 days, then crêped.
 Ref. No. 332 B1. Slab hot-air dried 2 days, then crêped.
 Ref. No. 332 C. Slab air-dried 3 days, then crêped.
 Ref. No. 332 C1. Slab hot-air dried 3 days, then crêped.
 Ref. No. 332 D. Slab air-dried 4 days, then crêped.
 Ref. No. 332 D1. Slab hot-air dried 4 days, then crêped.
 Ref. No. 332 E. Slab air-dried 5 days, then crêped.
 Ref. No. 332 E1. Slab hot-air dried 5 days, then crêped.
 Ref. No. 332 F. Slab air-dried 6 days, then crêped.
 Ref. No. 332 F1. Slab hot-air dried 6 days, then crêped.

Table 13 gives the rates of cure of the samples for one series, the experiment being repeated with similar results.

TABLE 13.

Ref. No.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
	Hours.	Hours.
332 S.1 A1.	2½	2½
332 S.1 B.	2½—2½	2½
332 S.1 B1.	1½	1½
332 S.1 C.	1½	1½
332 S.1 C1.	1	1½
332 S.1 D.	1½	1½
332 S.1 D1.	1	1
332 S.1 E.	1½	1½
332 S.1 E1.	1	1
332 S.1 F.	1½	1½
332 S.1 F1.	½—1	1

It will be seen from the above table that the same rate of cure is obtained by maturing and drying the slabs in a hot air chamber for three days (C1), as is normally attained at ordinary temperature in six days (F). Secondly, drying in hot air beyond the three-day period still further accelerates the rate of cure.

The results of this experiment confirm the marked effect, during the early stages of drying, of a temperature above the normal atmospheric, in accelerating the rate of vulcanisation.

An interesting feature of the above samples is the moisture content, before crêping, i.e., after the respective drying periods, to which each sample was subjected. The moisture contents are given in Table 14.

TABLE 14.

Ref. No.	A1.	B.	B1.	C.	C1.	D.	D1.	E.	E1.	F.	F1.
Moisture %	56.2	58.3	52.7	55.6	43.0	54.5	27.2	49.9	21.2	47.3	20.1

The importance of the above results, in connection with the preparation of rubber of this type for the market, is obvious and the method does not demand any drastic alterations in respect to special drying rooms. The ordinary smoke-houses can be utilised, but, instead of allowing the hot smoke products to act directly on the rubber in the rooms, only the heat from the furnaces is utilised and the smoke products are allowed to escape, by means of a flue attached to the furnace; the latter must be of such a type that smoke does not escape into the room.

The effect of fungus "spot" disease development on rubber.

It has been shown above, in connection with ordinary samples of slow curing crêpe, that, if this type of rubber is rolled into a cylinder while wet, in order to retain the moisture present, and thus endeavour to accelerate the rate of cure by inducing the necessary biological changes, no such change is produced, and that, in crêpe rubber rolled up in this manner, there is a very great

formation of pigment in the rubber due to the development and growth of various fungus spores.

It has since been found, however, that if similar thin wet crêpe is pressed into blocks by hydraulic pressure (the blocks prepared measured about 1 foot square by 6 to 9 inches thick), so that all the air between the thin layers of rubber was pressed out and the block was made solid, no pigmentation developed, except when the block was insufficiently pressed and air was occluded. This confirms the statement made above as to the necessity of air or oxygen in the development of the pigment in "spot" disease of prepared rubber. Secondly, while there was little or no acceleration in rate of cure in the thin wet crêpe rolled by hand into cylinders, which in each case was covered with "spot" disease, there was a marked acceleration in rate of cure in the blocked wet crêpe.

Table 15 gives the results for two series of the experiment, which was repeated on ten different dates with similar results.

TABLE 15.

Ref. No.	Type of rubber.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
		Hours.	Hours.
346 S.2 A.	Control crêpe.	3	3
346 S.2 B.	Block crêpe.	2½	2½
346 S.2 C.	Block crêpe.	2½	3
346 S.3 A.	Control crêpe.	2½—3	3
346 S.3 B.	Block crêpe.	2—2½	2½
346 S.3 C.	Block crêpe.	2½—3	3

The acceleration in rate of cure of the blocked wet crêpe (B) is seen clearly.

The following results, however, are of the greatest interest in this connection, and throw considerable light on the problem. Samples of slab were matured in the ordinary manner and converted to crêpe after the usual maturation period of six days or more. Two samples of this crêpe were then hung to dry in the ordinary way, and the third was taken direct from the crêping

machine and rolled into a cylinder. As in the case of ordinary slow-curing crêpe, a great development of "spot" disease took place. One of the remaining two samples, hung to dry, was, after being thoroughly dried, dipped into water for about 30 seconds, then removed and shaken in order to remove superfluous moisture and, in some cases, mopped with a cloth to remove more water, and then rolled into a cylinder and left for several weeks. These latter samples also developed "spot" disease, but not so extensively as in the case of the matured slab rolled into a cylinder immediately after crêping (i.e., before drying as thin crêpe).

(Note.—For development of "spot" disease in dry rubber allowed to become damp subsequently, vide *Agricultural Bulletin*, F.M.S., Vol. V., Nos. 5—6, February-March, 1917, "Note on the development of chromogenic organisms in dry rubber allowed to become damp," by the author.)

In the case of these fast-curing rubbers, the development of the "spot" disease has caused an extraordinary retardation in rate of cure, the most marked result being obtained, as would be expected, in the case of the crêpe rolled into a

cylinder direct from the crêping machine, in which the "spot" disease was most marked.

In most of the series of this experiment, the rate of cure was retarded by about 1 hour, while in two series the retardation was over 1½ hours under the conditions of vulcanisation employed.

The following are the samples prepared:—

- Ref. No. 340 A. Slab crêped and hung to dry.
 Ref. No. 340 B. Slab crêped and rolled into cylinder by hand, direct from the crêping machine.
 Ref. No. 340 C. Slab crêped and hung to dry, and dipped in water after having been dried and then rolled into a cylinder by hand.

Table 16 below gives the vulcanisation results for two series of the experiment:—

TABLE 16.

Ref. No.	Optimum time of cure from standard curve.	Optimum time of cure from maximum product.
	Hours.	Hours.
340 S.1 A.	1½	1½
340 S.1 B.	2	2
340 S.1 C.	1½	1½
340 S.7 A.	1	1
340 S.7 B.	2½	2½
340 S.7 C.	1½	1½

It remains now to seek a reason for the non-effect of "spot" disease in an ordinary slow-curing crêpe and the marked retardation in rate of cure produced by "spot" disease in a fast-curing rubber. The cause, in the light of our previous researches, is almost certainly due to the fact that, while the nitrogenous substances (protein chiefly) present in slow-curing crêpe have very little effect on its vulcanising capacity, the utilisation of any such protein by the fungi spores during development would not affect the rate of cure in this type of rubber. In a fast-curing rubber, however, the fungi utilise the simpler nitrogenous substances formed by the degradation of the protein, which act as vulcanisation accelerators, i.e., the fungi in their development destroy the accelerating substance or alter its composition, so that it no longer behaves as an accelerator, and the rate of cure of the fast-curing rubber affected with "spot" disease is retarded.

The experiment also illustrates the necessity in research of this description, of not basing general opinions on a particular type of rubber, and shows the value also of carrying out much of this research on the spot, where it is much simpler to follow up any particular clue.

In several series of the above experiment, the rolled-up rubber was not re-washed, after the development of the "spot" disease, but the rolls were unwound and the thin crêpe re-hung to dry in the ordinary way. The accelerator was not, therefore, removed by treatment with water, but must have been partly destroyed or converted into some derivative, which does not act as an accelerator of vulcanisation.

Another exceedingly interesting feature of the above experiment, but one on which the author desires to carry out further experiments, is that in the rubber in which the "spot" disease develops to the greatest extent (sample B), there has been a loss of some constituent or constituents in the gaseous form, apparently amounting to about 4—5% of the weight of the rubber. This is the first occasion, as far as the author is aware, on which it has been proved definitely that the development of fungoid growth on prepared rubber has a detrimental effect.

Tank v. pan sheet.

On many large estates during the last 2—3 years, large tanks have been substituted for the small enamelled iron coagulating pans formerly

in use. The average coagulating pan, or a type especially favoured, measures 18 in. long by 6 in. wide by 3½ in. deep, and holds approximately 1 gallon, when filled to the top. Large tanks holding 50—100 gallons, or even more, are constructed with division plates, so that the distance between these plates represent what in the coagulating pan was represented by the depth of latex employed, i.e., in the large tanks, sheet is coagulated sideways or edge on. This is done in order to economise floor space, and also it prevents surface oxidation of the coagulum, since the surface exposed now represents the edge of the sheet after the coagulum is rolled to sheet form. It is not proposed here to deal with the various types of such tanks nor with their economics, except to state that they have many advantages and were advocated by the author and others as long ago as 1912. One of the best, which the author has seen, was made by a manager of an estate and, generally speaking, these tanks represent a normal evolution of the plantation rubber industry, necessitated by increase of crops and area. The problem, to be discussed here, is their effect on the vulcanising capacity of the rubber and the results illustrate what a comparatively small variation in estate practice may cause variability in the product. This effect is due really to the type of tank adopted, or more especially to the method of division. Most tanks have the division plates about 1½ inches apart and this therefore represents the thickness of the unpressed coagulum, which is eventually rolled to sheet. As stated above, the ordinary coagulating pan is about 3½ inches deep and is usually filled with latex, for coagulation purposes. In the pans, therefore, we have coagulum 3½ inches thick. As might be expected, when coagulum 1½ inches thick from tanks, and coagulum 3½ inches thick from pans, is rolled between rollers at a fixed distance apart, the resultant sheet will be softer and will roll out thinner, by stretching laterally and longitudinally, from the 1½ inch coagulum, than from the 3½ inch coagulum, which will be harder and thicker after it leaves the rolls. The thinner and softer tank sheet will dry more rapidly and will vulcanise therefore more slowly, owing to the partial inhibition of the biological changes producing the vulcanisation accelerator. On the other hand, assuming that the tank sheet from 1½-inch coagulum is rolled only to such an extent that the final dry sheet is of the same thickness as that from 3½-inch coagulum, it will cure faster, since more of the serum is retained, owing to the smaller amount of rolling given to the 1½-inch coagulum to bring it to the same final thickness as the sheet from 3½-inch coagulum. Secondly the tank sheet from 1½-inch coagulum, prepared by the smaller amount of rolling, although of the same thickness as the pan sheet, will dry more rapidly owing to its more spongy and porous nature. The advantages in respect to vulcanisation capacity thus lie in favour of tank sheet, since to obtain a rubber which dries equally or even more quickly and also vulcanises faster, it is not necessary to roll the tank coagulum as tightly as the pan coagulum.

It can be seen from the above statement that the amount of latex placed in a pan of any particular size will also influence the vulcanisation of the resultant rubber (as sheet), if other factors are constant. The author has found this in several instances to be a cause of variability in estate practice.

The effect in the case of crêpe would be nil and, as will be seen also from slab samples, which are included in the tables, the effect of the difference in the thickness of the original coagulum is almost negligible. It can be stated, however, that 1½ inches is about the minimum thinness of coagulum in the preparation of slab rubber. Thinner

coagulum will dry too rapidly, thus inhibiting the essential biological changes.

Table 17 gives the vulcanisation results for samples of slab from tanks and pans, and also samples of sheet (unsmoked) from tank and pans, in which the same tightness of rollers was employed in the preparation of the sheets from tank and pan.

TABLE 17.

Ref. No.	Type of rubber.	Optimum time of cure from standard curve.	
		Hours.	Hours.
335 S.1 A.	Unpressed slab from pan (3½ in.).	1	1½
335 S.1 B.	Unpressed slab from tank (1½ in.).	1 — 1½	1½
335 S.1 C.	Sheet from pan.	2 — 2½	2½
335 S.1 D.	Sheet from tank.	2½ — 2½	3
335 S.2 A.	Unpressed slab from pan.	1 — 1½	1½
335 S.2 B.	Unpressed slab from tank.	1 — 1½	1½
335 S.2 C.	Sheet from pan.	2½ — 2½	2½
335 S.2 D.	Sheet from tank.	2½	2½

The retardation in cure of the tank sheet is seen from the table.

The following table gives the results obtained from sheet samples prepared from pans and tanks, but in this case two sheets from tank coagulation were made, one (B) being rolled to approximately the same final thickness as the pan sheet (A) and the other tank sheet (C) being passed between smooth rollers a similar number of times to A, the final tightness of the rollers for A and C being the same, whereas to obtain the same thickness for the tank sheet (B) as the pan sheet (A) it is not necessary to bring the rollers so close together.

The following, therefore, were the samples prepared:—

- Ref. No. 341 A. Unsmoked sheet from pan, from coagulum 3½ inches thick.
 Ref. No. 341 B. Ditto from tank, from coagulum 1½ in. thick, rolled to same final thickness as A.
 Ref. No. 341 C. Ditto from tank, from coagulum 1½ in. thick, rolled to the same extent as A.

Table 18 below gives the vulcanisation results in the case of two series of the experiment and also shows the thickness of the sheets.

TABLE 18.

Ref. No.	Thickness of sheet.	Optimum time of cure from standard curve.	
		Hours.	Hours.
341 S.8 A.	3.0	2½	2½
341 S.8 B.	3.4	2½	2½
341 S.8 C.	2.2	2½ — 2½	2½
341 S.9 A.	3.6	2½	2½
341 S.9 B.	3.4	2½	2½
341 S.9 C.	2.2	2½ — 2½	2½
341 S.10 A.	3.6	2½	2½
341 S.10 B.	3.0	2½	2½
341 S.10 C.	2.4	2½	2½

In this case it will be seen that the rate of cure of the pan sheet (A) and the tank sheet (B) of similar thickness, is approximately the same, while the tank sheet (C), the final thickness of which is much less, when rolled to the same extent and with the same tightness of rollers employed for rolling the pan sheet (A), cures more slowly.

It is interesting to compare the above results with the rate of drying, which was determined for the three series above. Table 19 gives the percentages of moisture in the samples, weighed at the same time, during the first six days of drying and the moisture on the 11th or 12th day, on which the samples were converted to crêpe.

TABLE 19.

Days after machining.	S.8. Moisture %.			S.9. Moisture %.			S.10. Moisture %.		
	A.	B.	C.	A.	B.	C.	A.	B.	C.

11	—	—	—	1.0	1.3	0.1	—	—	—
12	0.2	0.1	0.1	—	—	—	0.9	0.7	0.3

Rate of vulcanisation of tree scrap.

From our previous work, it might be concluded that tree scrap, being naturally dried latex, and therefore, as one would think, containing all the constituents of a concentrated latex, should cure rapidly, owing to the influence of the residual serum constituents, which are normally removed in washing and creping fresh coagulum. It has been found, however, that tree scrap has its optimum cure, under the conditions of vulcanisation employed in our laboratory, at about 2½—2¾ hours, which may be described as an intermediate rate of cure. A reason for this had therefore to be sought.

Experiments were carried out in which thin layers of latex were allowed to dry overnight on (A) glazed plates, (B) porous plates, and it was found that the former cured rapidly and the latter at about 2½—2¾ hours, that is more slowly. The reason for this, in the light of our previous researches, is obvious. The rubber from latex which has been dried in thin layers on glazed plates or vessels, does contain all the constituents of the rubber, while in the case of the latex placed on porous plates, a large proportion of the serum is absorbed by the plates; hence, the vulcanisation is retarded, as we are not dealing actually with a rubber which contains all the serum constituents. The freshly-cut channel on the tree acts as porous plate, and the tree scrap therefore does not contain all the serum constituents, since some portion is absorbed by the soft porous wood of the freshly-cut channel; and tree scrap, therefore, cures in a similar manner to rubber prepared by placing thin layers of latex on porous plates.

The natural accelerator of Para rubber.

Stevens has recently published a paper under this title (*vide* this J., April 16, 1917), which entirely confirms our researches, while going slightly further into certain details in connection with the vulcanisation accelerator or accelerators which the present author has found to be produced in plantation Para rubber by the degradation of the proteins, and also preformed in the latex and retained by the raw rubber under certain conditions of preparation. Whether these two accelerators are the same or different substances remains to be investigated. The author has shown that a greater amount of the serum residue (obtained by evaporation) is necessary to produce the same acceleration in rate of cure, as in the case of the degraded protein. It must be remembered, however, that we are not yet dealing with pure substances, and it may be that the serum residue contains a smaller proportion of the same substance which is produced in larger proportions by the biological degradation of the nearly pure proteins separated from the serum. If these accelerators are the same, it means that there is in latex itself simpler nitrogenous substances, as well as the complex proteins, and it is possible that the proteins are built up in the latex from these

simpler compounds, and can be degraded again by biological methods to produce the same compounds.

The author has not obtained the maximum acceleration which is obtained in slab, by adding these accelerators to a slow-curing rubber separately. No experiments, however, have been carried out by the author yet, by combining the two accelerators and noting their additive effect. If they are two distinct substances, it is possible that their additive effect may be greater than when used separately. In slab rubber, we undoubtedly have the effect of both, since, after the coagulum has been left to mature for six days, not only is a change undergone by the proteins, but the serum constituents are more difficult to remove from the partially dried rubber, and are therefore probably retained to a greater extent, in rubber of this type.

Referring again to Stevens' paper, the author would like to point out that Stevens has either not fully understood our previous papers or has obscured the real issue. He alludes to our previous work as follows:—"Eaton arrived at the conclusion that this insoluble matter has no effect on the rate of vulcanisation. His mistake arose from taking rubber already containing its full complement of nitrogenous matter, instead of working with a rubber from which the latter had been removed."

The author maintains, however, that no such mistake has been made. In our researches we were endeavouring to show why plantation Para rubber prepared in different ways varied in cure, and especially why ordinary crêpe rubber cures slowly and slab rubber (the latter being our own discovery) cures rapidly, and we were not dealing with the vulcanisation capacity of a synthetic caoutchouc or a rubber freed from such compounds, but with normal plantation samples. It soon became obvious to us from our own researches that ordinary crêpe rubber did not cure slowly on account of lack of proteins, but on account of a lack of a particular substance (not protein), which acts as an accelerator. Stevens in his previous researches had missed this, probably for reasons pointed out by the author and J. Grantham (this J., October 31, 1916). It is of interest to note also that after severely criticising the vulcanising mixture used by the author and by Schidrowitz, Stevens has, in the paper now referred to, adopted similar mixings.

If any mistake has been made, it was made originally by Stevens in connection with his earlier work, in which he appeared to think that the vulcanisation capacity of ordinary plantation rubber, which contains a full complement of protein, was connected with the protein matter *per se*, whereas our researches have shown this to be incorrect, although the author is not prepared to deny that proteins may have an effect on the vulcanising capacity of synthetic caoutchouc.

The author would also like to take this opportunity of replying to certain criticisms or replies of Stevens (this J., November 30, 1916) in reference to the paper on "The variability of plantation Para rubber with different technical mixings." Stevens, in his reply, alludes to the fact that probably 50% of manufactured rubber goods contain lead oxide, which, as our researches have shown, obscures the effect of the natural accelerator in Para rubber. The author is not in a position to dispute this fact, but fails to see that it is, in any respect, an argument against the effect of the natural accelerator, or its importance in connection with the variability in cure of plantation rubber for the remaining 50% of manufactured goods. Results of estate samples, which will be published shortly, show that, apart from our special slab rubber, the variability in rate of cure of estate samples has not been exaggerated, even at the present time, when uniformity

in preparation on estates is much greater than 4—5 years ago.

Stevens also refers to the fact that our explanation of the action of lead oxide, if correct, would also apply to magnesium oxide. The author fails to see why this should be so, since it is well known that different mineral accelerators produce different effects, and lead oxide, as far as the author is aware, is a much more powerful accelerator than magnesium oxide. While agreeing with Stevens as to the large number and amounts of different ingredients used for various purposes in modern rubber manufacture, in the author's opinion it would be a mistake to carry out research of this nature with such mixings—the simpler the mixing for such purposes the more likely is one to effect the isolation of variables responsible for the different vulcanising capacity of various raw rubbers. Ample confirmation of the results of our researches in connection with variability in rate of cure, has been received from various well known rubber manufacturing firms, who should be in a position to realise the effects, without perhaps being aware of the causes, and it is difficult therefore to understand Stevens' attitude in attempting to minimise these variations.

Finally, with regard to the relationships between the curves, while not strictly in arithmetical progression, they are very close, as can be seen by comparing the different curves. The explanation lies in the curves themselves, if these, as we believe, can be taken to represent the state of cure of the rubber. There certainly does not appear to be any more reason for adopting a geometrical than an arithmetical progression in the relationships.

It may be stated here, a point which was omitted in our previous paper under discussion, that the experiments described were not carried out as a reply to Stevens' criticisms, but were actually done in 1915 and would not have been published at the time had Stevens not raised the question of the type of mixing, since the experiments with these "mineral" mixings were admittedly incomplete.

Summary.

1. The experimental results on variability in rate of vulcanisation of plantation Para rubber, described here, confirm previous work by the author and his collaborators and theories deduced from these researches and give results of additional interest.

2. Various types of experiments, in connection with the rate of drying of freshly machined coagulum, show that the moisture content of the coagulum is the most important factor determining rate of vulcanisation and also confirm previous work by the author on the presence of a second accelerating substance, preformed in Hevea latex.

3. Acceleration in rate of cure can be induced even in thin crêpe by blocking the thin wet crêpe under pressure, so as to exclude air.

4. For the formation of pigment, known as "spot" disease, which is evidence of the development and growth of the spores of certain chromogenic micro-organisms, not only moisture but air or oxygen is essential.

5. The development of these micro-organisms on a slow-curing crêpe rubber has little or no effect on its vulcanising capacity, in respect to rate of cure, since thin crêpe contains none of the vulcanisation accelerator present in "slab" crêpe.

6. Similar development of micro-organisms in "slab" crêpe causes a marked retardation in rate of cure, due undoubtedly to these organisms utilising the accelerator, or altering its composition.

7. In the development of "spot" disease in rubber, there appears to be a considerable loss of some constituent, which is removed in the gaseous form. Further researches on this point are necessary.

8. The progressive change which takes place in slab during the first 6—7 days of drying or maturing, also takes place in sheet up to this period. From these results, any type of rubber can be converted into thin crepe, after six days' drying, without affecting its rate of cure.

9. In the smoking of rubber, two variables are concerned: (a) antiseptic effect of the smoke products; (b) temperature of drying. The former retards the rate of cure of the rubber, and the latter, within the limits used in practice, accelerates the rate of cure. Hence, smoked sheet may cure faster or slower than similar unsmoked sheet, depending on the balance of these two factors during the early stages of smoking.

10. Drying by hot air not only accelerates the

rate of cure, but reduces the ordinary maturation period of slab from six to three days.

11. The concentration of the latex affects the rate of cure of the coagulated rubber, owing to the different amounts of accelerator retained in the rubber, under similar conditions as to machining.

12. Tree scrap has a comparatively moderate rate of cure, instead of a rapid rate of cure, as might have been expected, owing to the fact that it does not contain all the serum constituents, which are absorbed partly by the freshly cut porous channel on the tree.

Note.—Further work on various aspects of the problem is contained in various numbers of the *Agricultural Bulletin*, F.M.S., published monthly.

The special bulletin, which contains the results of all the researches to date, except the experiments which are in progress, will be published very shortly and may be obtained on application to the author or the Director of Agriculture, F.M.S.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, *Bells et Cie.*, 56, Rue Ferou 8. Paris (3e.).

Patents from 1908 to date, *L'Imprimerie Nationale*, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Liquids: Handling and transportation of.—

M. H. Eisenhart. *J. Ind. Eng. Chem.*, 1917, 9, 980—982.

WHEN purity is not an essential factor, tank cars are used for transporting nitric and sulphuric acids between plants, but for hydrochloric and acetic acids small containers are generally used, the latter acid being frequently shipped in wooden barrels. To ascertain the most suitable metal for the pipes, valves, etc., in any particular case it is advisable to suspend strips of apparently suitable metals in the liquid, and to note the effect both of the liquid and the fumes. Steel is almost exclusively employed for the sulphuric acid and mixed acids used in the manufacture of nitro-cellulose, although it is unsuitable for nitric acid alone. For the latter and for the lower strengths of sulphuric acid the alloys of iron and silicon ("duriron," "tantiron," etc.) are suitable, and have replaced stoneware in many places. Silica ware is now in considerable use for pure chemicals, for, although as fragile as glass, it can resist changes of temperature without breaking. For the handling of weak acid solutions wood is well adapted. Aluminium is not suitable for alkalis, but may be used with glacial acetic acid and with very weak solutions of nitric and sulphuric acids. Enamelled iron is being used in many directions for kettles, piping, and special apparatus, and is particularly suitable for brewery plant and for the handling of many food products. Satisfactory results have also been obtained by the use of pipes lined with tin, copper, lead, etc. For moving liquids in general and particularly nitric and sulphuric acids, air pressure is the most simple and least troublesome method. For valves alloys of iron and silicon have proved satisfactory when subjected to acid fumes, and have lasted for three to four years, where previously the ordinary valves required renewal every three or four weeks.—C. A. M.

Liquids: Storage and transportation of.— F. R. Baxter. *J. Ind. Eng. Chem.*, 1917, 9, 978—979.

AN outline is given of the methods of transporting oil by tank steamers and pipe lines. The lines from the Kansas fields to New York contain, when full, 760,159 barrels of crude oil, the value of which, according to the quotations of May, 1917, was \$1,444,302. The pipes are made of wrought iron and are tested up to a pressure of 1200 lb. The crude oil at the wells is usually stored in wooden tanks of a capacity of 250 barrels and upwards. It is estimated that by 1927 the U.S. Navy will annually require 10,000,000 barrels. To meet this demand two oil areas have been reserved in California and one in Wyoming, and will not be drilled until the oil is required.—C. A. M.

Liquids: Transportation and storage of— in small packages.— L. R. Adkins. *J. Ind. Eng. Chem.*, 1917, 9, 979—980.

THE wooden barrel used in the petroleum industry in the Eastern United States is made of red and white oak, and is coated inside first with an adhesive substance such as vegetable gum, by-products of the sugar industry, or water glass, and then with a good hide glue. In recent years iron barrels have been replacing the wooden barrels. They are made by rolling sheet iron on heavy presses, and are welded by means of gas or electricity. The cylindrical form is preferable to the ordinary barrel shape as it stands more wear and tear. The chief disadvantage in the use of the iron barrel is that the iron oxide is liable to flake off the interior and contaminate the liquid. Tin cans for the petroleum trade are made from tin or terne plate of 26 to 28 gauge, and enormous quantities of kerosene are exported to all parts of the world in the standard 5-gall. cans.—C. A. M.

PATENTS.

Evaporator and boiler feed-water heating apparatus for power plant; Combined —. The Griscom-Russell Co., New York. Assignees of R. C. Jones, Garden City, N.Y., U.S.A. Eng. Pat. 103,644, Dec. 21, 1916. (Appl. No. 18,336 of 1916.) Under Int. Conv., Jan. 26, 1916.

THE vaporisation temperature of the evaporator is regulated by a reducing valve to accommodate the system to varying loads on the boiler. The distillate from the evaporator passes first through a boiler feed-water heater and then through a primary heater for the water to be evaporated. The liquid to be evaporated is also passed through a secondary heater, through which the unevaporated liquid from the evaporator is passed in a contrary direction.—W. H. C.

Valves for use in evaporating apparatus. Kestner Evaporator and Engineering Co., Ltd., J. A. Reavell, and W. G. Mann, London. Eng. Pat. 110,180, Oct. 6, 1916. (Appl. No. 14,221 of 1916.)

THE valve casing is provided with a removable sleeve or liner having an inclined valve seating at the lower end against which the valves abuts. By providing a full, straight passage for the liquid instead of the usual sinuous path, deposition of salts from concentrated liquors is prevented to a large extent.—W. H. C.

Power presses for extracting liquids from vegetable matter or other material. J. C. Fiddiment, Baltimore, Md., U.S.A. Eng. Pat. 110,035, Oct. 16, 1916. (Appl. No. 14,683 of 1916.)

A PRESS for extracting liquid comprises an outer shell having slightly tapering inner walls, and a concentric inner rotating compressing member for conveying the material through the press and expressing the liquid. The compressing member comprises a number of flanged discs, threaded on a shaft, each disc having a groove in which a pair of loose rings are mounted and are adjustable to vary the width of the annular space on each side of them between the flanges. The discs are bored longitudinally for the insertion of a conveyor screw rotated by gearing from the main shaft and passing through all the annular spaces in the discs. The material is fed in at one end and is transferred from one groove to the next by fixed inclined abutments in the grooves. The material is prevented from being carried round by the compressing member by a parallel rotating member below it at the inlet end, having flanges which enter the annular channels. The expressed liquid escapes by the conveyor channel and also by circumferential openings in the shell.—W. F. F.

Expressing liquid from materials containing the same; Processes for —. J. W. Hinchley, London, and G. Gorton, Bexhill-on-Sea. Eng. Pat. 110,379, Oct. 13, 1916. (Appl. No. 14,601 of 1916.)

IN apparatus of the type described in Eng. Pats. 101,782, 108,503, 110,381, and 110,384 (this J., 1916, 1254; 1917, 998 and following), sewage sludge, fish refuse, oilseeds and nuts such as palm kernels and copra, crushed beetroot, and sugar cane, may be treated at a preliminary pressure up to 0.5 ton per sq. in., the steam admitted up to a pressure of 200 lb. per sq. in., and temperature up to 380° F. (193° C.), and the final pressure may be up to 2 tons per sq. in.—W. F. F.

Expressing liquid from materials containing the same; Apparatus for —. J. W. Hinchley, London, and G. Gorton, Bexhill-on-Sea. Eng. Pats. (A) 110,381 (Addition to Eng. Pat. 101,782) and (B) 110,384, Oct. 13, 1916. (Appl. Nos. 14,603 and 14,606 of 1916.)

(A) IN apparatus of the type described in the

principal patent (this J., 1916, 1254), the orifices for the admission of fluid to the material in the cylinder are separate from those for the discharge of expressed liquid and are provided with non-return valves. (B) IN apparatus of the type described in Eng. Pats. 101,782, 108,503, 110,379, 110,381, and 110,383 (this J., 1916, 1254; 1917, 998, p. 1230, and preceding), the strainer or filtering surface is protected by a steel perforated liner or plate against which the piston slides.—W. F. F.

Expressing liquid from materials containing the same; Processes and apparatus for —. J. W. Hinchley, London, and G. Gorton, Bexhill-on-Sea. Eng. Pat. 110,382, Oct. 13, 1916. (Appl. No. 14,604 of 1916.)

IN processes and apparatus of the type described in Eng. Pats. 3998 of 1915, 101,782, 108,503, 110,379, 110,381, and 110,384 (this J., 1916, 1254; 1917, 998, and above), the treating fluid is cold air or water. Two or more hot or cold gases or liquids may be admitted successively to the press and the mechanical pressure may be constant or variable.—W. F. F.

Concentration of vitriol and other liquids; Apparatus for use in the —. F. Brown, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 110,183, Oct. 9, 1916. (Appl. No. 14,321 of 1916.)

A CASCADE concentrator is fitted with basins each of which has two spouts. The inlet spout of each basin rests on the edge of the support of the basin next above and the outlet spout rests in the inlet spout of the basin next below.—W. H. C.

Filtering; Process of —. M. B. Lamb, Santiago, Chili. Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,242,355, Oct. 9, 1917. Date of appl., June 22, 1914.

A FILTER cake containing a "desirable substance," e.g., sodium nitrate, and an "undesirable substance," e.g., sodium chloride, is washed with a solution of the latter; in the case mentioned the sodium nitrate is removed and the chloride left in the cake, preventing its collapse.—W. H. C.

Drying apparatus. B. Panara, Rome, N.Y. U.S. Pat. 1,242,368, Oct. 9, 1917. Date of appl., Apr. 23, 1917.

A NUMBER of superimposed tiers of separate drying rooms, provided with doors at the sides, have a ventilating chamber on the top, from which a fan blows air through the top tier of drying rooms. Means are provided for connecting any of the drying rooms with, or shutting them off from, the air current and from communication with the other drying rooms.—W. H. C.

Drying-machine. W. M. Brownell, Brooklyn, N.Y., Assignor to A. N. Hood, Newton, Mass., and J. T. Nightingale, Boston, Mass. U.S. Pat. 1,242,518, Oct. 9, 1917. Date of appl., May 1, 1916.

THE material to be dried is sliced by a knife and then forced under pressure through a number of drying tubes surrounded by a heating chamber. The tubes have constrictions at each end, and the discharge ends of the upper tubes project beyond those below.—W. H. C.

Separator or clarifier; Centrifugal, self-balancing —. H. A. Riggs, Indianapolis, Ind. U.S. Pat. 1,242,863, Oct. 9, 1917. Date of appl., Jan. 7, 1916.

A SEPARATING drum provided with conical discs, and having a hollow centre, is mounted pivotally on a rigid vertical shaft which passes into, and is of smaller diameter than, the hollow centre. Bow-shaped springs are interposed between the shaft and the lower part of the hollow centre.—W. H. C.

Centrifugal machines [hydro-extractors]. T. Broadbent and Sons, Ltd., and H. Broadbent, Huddersfield. Eng. Pat. 110,215, Oct. 27, 1916. (Appl. No. 15,301 of 1916.)

IN a centrifugal nitrating machine, an inner detachable conical lining is provided between the basket and the central support; this serves to protect the working parts of the machine from acid, and it can be removed and replaced without disturbing the working parts. The lining is attached either to the outer casing of the machine or to the central support. The change from low to high speed of rotation is effected by means of a hand lever and cam.—W. H. C.

Separating liquids from gases, particularly applicable for separating oil from steam; Apparatus for —. The British Thomson-Houston Co., Ltd., London. F. S. Carter, Port Talbot, and F. Samuelson, Rugby. Eng. Pat. 110,219, Nov. 1, 1916. (Appl. No. 15,610 of 1916.)

THE gas is passed through a chamber in which a number of perforated discs mounted on a horizontal shaft are rotated between a number of perforated discs fixed to the chamber walls. The separated liquid is discharged from the bottom of the chamber. A fan may be fixed on the shaft so that the discs are rotated by the action of the current of gas on the fan.—W. H. C.

Furnace gases; Removal of dust from —. H. P. Bingham, London. Eng. Pat. 110,235, (Appl. Nos. 16,795, Nov. 23, 1916, and 7390, May 22, 1917.)

IS a dust filter of the type in which the dust-laden gases pass horizontally through a bed of broken brick or other filtering material contained in a chamber between two louvered walls, the discharge of the filtering material is controlled by a ram or articulated system of bars or plates, which may be moved so as to grip the filtering material in the upper part of the discharge neck and hold up the material above, while that below falls out when a sliding damper, on the lower end of the discharge neck, is withdrawn. The louvered grids on the inlet side are set in an inclined frame, which extends only half way up the chamber, and those on the outlet side are set in a vertical frame and extend the whole height of the chamber. The louvres are formed with vertical webs to prevent sagging.—W. H. C.

Air and the like cleaning devices. Babcock and Wilcox, Ltd., London, and D. C. Meikler Reid, Lee, Kent. Eng. Pat. 110,275, Feb. 23, 1917. (Appl. No. 2669 of 1917.)

DUST-LADEN air is carried into a depositing chamber by vacuum or pressure and is sprinkled with a refuse-depositing medium (e.g., water) during its passage through the inlet pipe. The depositing chamber is provided with screens, which are sprayed with the depositing medium on the discharge side from a number of spraying devices, so arranged that the areas sprayed overlap.

—W. H. C.

Filling materials for reaction, concentration, or absorption towers and the like. C. J. Goodwin, London. Eng. Pat. 110,260, Jan. 23, 1917. (Appl. No. 1165 of 1917.)

THE filling material has the form of two truncated cones joined together at their smaller ends. The joint is smoothed or rounded off and an external collar may be provided round the joint. The cones may have perforations, corrugations, or serrations to increase their efficiency, and may be constructed of metallic or other suitable wire.

—W. H. C.

Steam boilers and the like; Coal-fired —. G. Wilkinson, Harrogate. Eng. Pat. 110,385, Apr. 2, 1917. (Appl. No. 14,612 of 1916.)

A STEAM boiler is placed by the side of and combined with a vertical retort for distilling coal. Coke is discharged from the retort on to a firegrate and the hot gases pass upwards round the retort to heat it, and also over a group of boiler tubes in flues on each side of the furnace. Baffles may be provided in the flues to distribute the hot gases. The rate of coal distillation may be accelerated by drawing hot gases from the furnace through the retort. Fresh coal is fed into the retort at a rate corresponding to the discharge of coke and therefore to the rate of combustion of coke in the furnace. (See also Eng. Pat. 782 of 1915; this J., 1916, 247.)—W. F. F.

Refrigerating apparatus. E. C. R. Marks, London. From Isko Incorporated, Detroit, Mich., U.S.A. Eng. Pat. 110,533, Oct. 13, 1916. (Appl. No. 11,402 of 1917.)

THE pressure in the expansion coil of a refrigerator is maintained equal to that of the atmosphere by means of an automatic valve which controls the passage of the refrigerant from the condenser to the expansion coil. The valve is operated by a diaphragm, one side of which is exposed to the pressure within the expansion coil and the other side to the pressure of the atmosphere. A by-pass is provided to allow the refrigerant to pass back to the condenser, should the pressure within the expansion coil rise above that of the atmosphere. Expansion coils of special shape are also claimed.

—W. H. C.

Grinding mill. J. W. Cover, Tacoma, Wash. U.S. Pat. 1,242,423, Oct. 9, 1917. Date of appl., Oct. 28, 1916.

A HORIZONTAL rotating drum is provided with a number of axially spaced rings within the drum which support and act as runways for loose longitudinal grinding bars. The material is circulated by flanges projecting inwards from the outer shell, and the pulverised material passes outwards through a perforated peripheral screen forming the cylindrical wall of the drum.—W. F. F.

Liquids; Apparatus for treating — with gases. M. H. Ittner, Jersey City, N.J. U.S. Pat. 1,242,445, Oct. 9, 1917. Date of appl., Jan. 6, 1916.

LIQUID is contained in a closed receptacle into which gas under pressure is admitted at the top. A central vertical tube, perforated at the portion above the liquid level, is supported by the cover, and a rotating vertical shaft passes down through the tube and carries a centrifugal distributor at the bottom having also a central opening for the admission of liquid. Gas passes downwards through the tube, and means are provided in the distributor for intimately mixing the gas and liquid. The mixture is projected outwards into the main body of liquid under a pressure which alternates rapidly and abruptly with respect to the average pressure in the receptacle.—W. F. F.

Tunnel dryer for drying bricks, retorts, and the like. Eng. Pat. 110,531. See VIII.

Separating liquids from solids in fluid suspensions; Apparatus for —. A. L. Blomfield, Denver, Colo., U.S.A. Eng. Pat. 110,188, Oct. 10, 1916. (Appl. No. 14,415 of 1916.)

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Distillation of — under pressure. J. H. Capps and G. A. Hulet. J. Ind. Eng. Chem., 1917, 9, 927—935.

THE coal was heated by means of an electric furnace in a steel cylinder, into the neck of which was brazed a brass side tube, which conducted the distillation products first into a vertical seamless steel tube surrounded by an external heater, and then, through a cold water jacket, into a second receiver of glass, whilst the uncondensed gases, after passing through bulb tubes containing standard acid to absorb ammonia, were collected over water. The temperature was measured by means of a thermo-couple within the furnace just outside the retort. The pressure was obtained by confining the gases liberated from the coal, until at the desired point the cock was opened, and the gases allowed to escape as fast as they formed. Samples of steam coal, bituminous, sub-bituminous, and soft coals were thus examined. It was found that pressures up to 20 atmos. reduce the amounts of compounds of high b.pt., but increase those of low b.pt. in the condensable vapours evolved from coal below 600° C. They also cause an increase in the proportion of aromatic compounds of low b.pt. in the condensed oils. These results are due to the "cracking" of the vapours of the heavier compounds within the retort. As a rule, the amounts of phenols and acid compounds are also reduced by pressure. The proportion of coke and the amount of fixed carbon in the coke are increased by pressure, owing to the effects of cracking oils in contact with the coal. The calorific value of the coke is also increased, but the proportions of nitrogen, oxygen, sulphur, and volatile substances are reduced, probably through the increased partial pressure of hydrogen in contact with the hot coke. An increase in the volume of gas evolved from coal below 600° C. is produced by pressure. The amount of hydrogen in the gases is increased by pressures up to 20 atmos. at 500° C., but reduced at 550° and 600° C., the increase being attributable to "cracking," and the decrease to the action of the hydrogen on the nitrogen, sulphur, and oxygen in the coke, and upon the unsaturated compounds produced by the cracking. This view is supported by the increase of ethane and methane in the gases.

—C. A. M.

Naphthalene [in gas manufacture]; The production and prevention of —. T. D. Miller. Amer. Gas. Inst. News, Sept., 1917. Gas J., 1917, 140, 27—28, 78—80.

THE author advocates the use of high temperatures and heavy charges carbonised for a sufficient time to extract the gas completely from the coal, and shows that, provided the charges are heavy, i.e., from 475 lb. to 500 lb. in a 16 in. by 20 in. by 9 ft. retort, standpipe and naphthalene troubles do not occur. There appears to be general agreement that any of the hydrocarbons of coal gas or carburetted water-gas is convertible into naphthalene, the latter not being a direct result of high temperature processes but a secondary result of the heating of the gas after its generation. As the breaking up process in superheating gas causes dissociation of the hydrocarbons into carbon and hydrogen (depositing soot), any process which tends to reduce the formation of naphthalene also tends to a reduction of soot, which is the basis of stopped standpipe troubles. Naphthalene in water-gas practice is due to

excessive heats in the superheater, but as this heat is controllable the production may be limited. Experience seems to indicate that the production of naphthalene in vertical retorts is inconsiderable, probably owing to the fact that the passages by which the gas leaves the body of the coal are exceedingly small, and hence the velocity of the gas is increased and the length of exposure to the heated walls of the retort or to the body of incandescent coke is reduced. The cracking effect of various temperatures seems to be in inverse ratio to the time of exposure, i.e., exposure to a low temperature for a certain period will have the same effect as exposure to a higher temperature for a shorter period. Carbonising at low temperatures can be so conducted that there will be a practical absence of naphthalene. If on increasing the temperature the gas could be conveyed from the retorts without subjecting it to the cracking effect of the higher temperatures, the production of naphthalene would remain practically nil. The desirability of carbonising at high temperatures being apparent, it is obvious that in order to prevent undue superheating of the gas, the conveying space should be reduced as the temperature is increased to secure greater velocity. A series of replies to questions addressed to members of the Institute is included. The opinion is commonly expressed that the products of distillation remain too long in contact with the retort walls, but an improvement is noted with full, even, and regular charges. In the case of a vertical retort the gases pass through a cool zone of uncarbonised material and suffer only slight decomposition, whilst with coke ovens the temperature of the top of the oven may be kept low if the design permits. Opinion is unanimous on the absence of naphthalene troubles in vertical retort practice, and on the advantage of heavy charges, thereby increasing the velocity of the gas by reduction of the free space.—J. E. C.

Benzol extraction on gas works. J. H. Clegg. Manchester District Jun. Gas. Assoc., Nov. 3, 1917. Gas J., 1917, 140, 261—263.

THE author describes a Hird continuous plant used for benzol extraction, and gives an account of observations and experiences in working it. The plant consists of a rectangular still heated by coal gas. The oil traverses the bottom of the still around baffle-plates, a depth of one foot being maintained in the still. A dephlegmator is provided, and the hot oil passes through four heat interchangers, the first two being cooled by incoming oil, the others by cold water. The vapours pass through a condenser and the condensed products are separated, benzol and water being collected in separate drums. The benzolised oil flows through the plant by gravity from an elevated store tank. The scrubber washer is of the Holmes rotary brush type in two sections, the second section only being used for benzol washing, with creosote as the washing medium. A little water in suspension in the oil causes no trouble, but free water at the bottom of the still causes frothing. The benzol is sold on a standard of 65% distilling over at 120° C., with a reduction of ¼d. per gallon for every 1% below this standard. The best working temperature of the still is from 265° to 275° F. (120°—135° C.) at the outlet, this giving the greatest quantity of the required quality. If the quality is too good a little steam is admitted near the inlet; the action of the steam is mechanical, facilitating the release of vapours by agitation. In washing the gas the temperature of the wash oil is kept at about 58° to 65° F. (14°—18° C.) and a saturation of 3.3% is obtained, with a yield of 1½ gallons per ton. The reduction in candle power of the gas averages 25%, as also does the reduction in gross calorific value. About half a gallon of benzene and toluene per ton of

coal is retained in the gas. The wash-oil removes hydrogen sulphide from the gas to the extent of about 100 grains per 1000 cub. ft. The heavy distillates from the depilegmator are run off into a settling pan, giving a naphtha containing little naphthalene, and as much as 6% of tar acids, although the original ecreosotes contained none. Naphthalene troubles have been experienced owing to the washed gas having re-absorbed deposits of naphthalene of some years' standing; no naphthalene passed the holders. For working the plant about 70 cub. ft. of gas is required per gallon of benzol produced. The storage tank for benzol is laid about 2 feet in the ground on concrete, with a low brick wall surrounding it to confine the benzol in case of leakage.—J. E. C.

Combustion; Some observations on the effect of the partial pressure of oxygen in— H. C. Dollwig, A. C. Kolls, and A. S. Loevenhart. J. Amer. Chem. Soc., 1917, 39, 2221—2231.

In experiments with a candle and with a lamp burning ethyl alcohol at an asbestos wick in atmospheres containing various proportions of oxygen and nitrogen, it was found that extinction occurred when the partial pressure of the oxygen was reduced to 116 mm. and 112.7 mm. of mercury respectively, the corresponding proportions of oxygen being 15.1% and 16.1%; hydrogen continued to burn in the mixture until the percentage of oxygen was reduced to 6.63. When the partial pressure of the oxygen in air was reduced by gradual exhaustion of the combustion chamber, the flame of a paraffin or tallow candle became extinguished at a partial pressure of oxygen of 19 mm.; the corresponding value for an alcohol lamp was 27 mm. partial pressure, the relative proportion of nitrogen to oxygen being approximately the same as in air. The wide difference between the results under the two sets of conditions is to be attributed to the cooling effect of the excess of nitrogen in the former case, and also possibly, in some degree, to the inert gas interfering with the access of oxygen to the flame.

PATENTS.

Peat; Process for expressing liquid from— Processes and apparatus for expressing liquid from peat. J. W. Hinchley, London, and G. Gorton, Bexhill-on-Sea. Eng. Pats. (A) 110,380 (Addition to Eng. Pat. 3998 of 1915) and (B) 110,383, Oct. 13, 1916. (Appl. Nos. 14,602 and 14,605 of 1916.)

(A) In the process for expressing liquid from peat as described in the principal patent (this J., 1916, 1254), steam at 70—100 lb. per sq. in. is used, the temperature of the peat being about 90° C. (B) In processes and apparatus for expressing liquid from peat as described in Eng. Pats. 3998 of 1915, 101,782, 108,503, 110,381, and 110,384 (this J., 1916, 1254; 1917, 998, p. 1227), the treating fluid is hot liquid, e.g., hot water. Two or more hot or cold gases and hot liquids may be admitted successively to the press and the mechanical pressure may be constant or variable.—W. F. F.

Gas; Production of— from peat, lignite, or wood. C. O. Rasmussen, Copenhagen. Eng. Pat. 101,152, Aug. 7, 1916. (Appl. No. 11,136 of 1916.) Under Int. Conv., Aug. 8, 1915.

Gas produced in the usual way from peat, lignite, or wood, is passed together with steam or hydrocarbons through one or more closed retorts con-

taining substances consisting mainly of carbon (coke or charcoal) and maintained in a state of incandescence.—J. E. C.

Fuel; Hydrocarbon— for use in internal combustion engines. P. H. King and J. A. Stoneham, London. Eng. Pat. 110,520, June 15, 1917. (Appl. No. 8573 of 1917.)

A MIXTURE of acetylene (98%) and water-gas (2%) is mixed with an equal volume of hydrocarbon vapour and the whole condensed to form a liquid containing the acetylene and water-gas in solution. The hydrocarbon vapour may be obtained from petroleum or coal-tar derivatives having a flash point of about 85°—100° F. (29°—38° C.).—J. E. C.

II.B.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Lignite coal; Distillation of— at low temperatures. H. K. Benson and L. L. Davis. J. Ind. Eng. Chem., 1917, 9, 946—949.

A TYPICAL sample of Tono (Washington) black lignite was used for the distillation. It had the following composition:—Moisture, 20.2; volatile substances, 31.5; fixed carbon, 39.9; ash, 8.4; sulphur, 0.52; and nitrogen, 1.06%. B.Th.U., 9280 cal. At the present time this coal is only used as a steam coal in locomotives of special construction. As the result of a series of distillations at temperatures up to 600° C., it was found that the maximum yield of lignite oils (about 5.5% of the coal) is obtained at 380° C. These crude oils resemble petroleum and shale oils more closely than coal tar, being free from benzene or benzene derivatives. They yield valuable solvent, illuminating, engine, and lubricating oils. For example, at 380° C. the following yields per ton of lignite were obtained:—Crude tar, 108; light oil, 25.8; medium oil, 29.3; paraffin wax, 6.9; and paraffin oil, 38.9 lb. The amounts of gas obtainable (e.g., 4400 cub. ft. at 380°; 9800 cub. ft. at 600° C.) are small, and its calorific value is low. Small amounts of ammonia may be obtained from lignite tar water, but cyanides are only present in traces in the products of distillation at higher temperature. The residual coke is dull black and retains the shape of the original particles. It is of high calorific value (over 12,000 B.Th.U. per lb.), and its heating power increases with the temperature of distillation. The coke obtained at 380° C. (1092 lb. per ton) had the following composition:—Volatile substances, 14.0; ash, 13.0; and nitrogen, 0.5%. B.Th.U., 12,710 cal.

—C. A. M.

PATENT.

Distilling coal, wood, peat, or lignite for obtaining useful liquid and solid products. W. Thomas, Nanaimo, British Columbia. Eng. Pat. 110,217, Oct. 30, 1916. (Appl. No. 15,450 of 1916.)

HOT gas from coal or other material is passed in contact with one side of a double surface condenser and is partially cooled, thereby causing condensation of hydrocarbons. The cooled gas is further purified to remove sulphur, and then

passed in contact with the other side of the condenser and thence through a regenerative system, where it becomes heated to a temperature between 1600° and 1800° F. (870°—980° C.). The hot purified gas is then brought into intimate contact with a body of coal or other material, which may also be heated externally, thus effecting rapid distillation and carrying off sulphur, producing desulphurised fuel.—J. E. C.

III.—TAR AND TAR PRODUCTS.

Aniline; Colorimetric determination of small amounts of—. E. Elvove. J. Ind. Eng. Chem., 1917, 9, 953—955.

AFTER a preliminary test, the solution is diluted so as to fall within the limits of 1 part in 285,000 and 1 part in 2 millions of aniline. 20 c.c. of this solution is mixed with 1 c.c. of calcium hypochlorite solution containing 0.1% of available chlorine, and, after standing for 2 mins., is treated with 1 c.c. of N/1 sodium hydroxide solution, and allowed to stand for 10 mins. (or 5 mins. in the case of the lowest standard, containing 0.01 mgrm. of aniline). The colour of the liquid is then compared with the colour of standards containing from 0 to 0.07 mgrm. of aniline in 20 c.c. of water. The average error in test experiments was 0.003 mgrm.—C. A. M.

Benzol extraction on gas works. Clegg. See 11A.

Asphalt cauldrons, tar boilers, and the like. W. H. Wood, Birmingham. Eng. Pat. 110,175, Sep. 6, 1916. (Appl. No. 12,602 of 1916.)

THE cauldron or boiler consists of a pan placed over a fire-box, each being surrounded by an outer casing. The conical fire-box is strengthened against distortion by corrugations or grooves, or by curving the wall inwards. The two outer casings are barrel-shaped, and are provided inside with annular flanges, for securing them together and for holding the fire-box and pan in position. The fire bars pass through perforations in vertical flanges at the bottom of the fire-box, and the fire-doors are not flush with the outer casing but inside and protected by it.—F. Sp.

Distillation [of benzol, etc., from wash oils]; Process of— and still for carrying out the same. Simon-Carves, Ltd., and J. H. Brown, Manchester. Eng. Pat. 110,413, Oct. 28, 1916. (Appl. No. 15,390 of 1916.)

TO recover benzol, toluol, naphtha, etc., from the oil with which they have been absorbed in the washing of coal gas, the oil is heated to about 130°—140° C. and passed downwards over a series of horizontal trays at the top of a column still. On leaving the lowest tray the oil, cooled to about 105°—108° C., passes downwards to the bottom of an annular chamber containing a steam coil which reheats it to the initial temperature. The oil overflows the inner rim of the annular chamber and passes downwards over a series of inclined splashing plates to another series of horizontal evaporating trays where the remainder of the absorbed substance is liberated. The oil then passes to the lowest chamber of the still, which contains a coil through which the incoming oil is passed to preheat it.—W. F. P.

Cresole oil substitute and process of making same. G. E. Heyl, London. U.S. Pat. 1,242,188, Oct. 9, 1917. Date of appl., Feb. 21, 1917.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Distillation of mixtures of nitric and sulphuric acids. Pascal. See VII.

PATENTS.

Refuse, fibrous or the like material; Treatment of—. W. S. H. Bevin, Liverpool. Eng. Pat. 110,394, Oct. 18, 1916. (Appl. No. 14,791 of 1916.)

THE process relates to the treatment of waste fibrous or textile material with the object of separating seeds, husks, etc., in a condition enabling them to be used as a cattle food, and of recovering the fibres. The material is fed to a pit from which it is lifted by air suction to the top of the apparatus, any stones and heavy matter falling back to the pit. At the top of the apparatus the material is delivered into a centrifuge from which it falls on to a flocking machine consisting of beaters which shake out the seeds and similar matters; the fibrous material passes through a revolving wire mesh cylinder, that portion delivered at the end being caught in a bag, and that portion passing through the mesh being passed through a second wire mesh tube of hexagonal form, thus dividing the fibrous material into first and second grade fibres. The

material passing through the mesh of the hexagonal tube is returned to the commencement of the apparatus for re-treatment. The seeds and other matter separated by the flocking machine pass over a magnetic roller to remove iron wire, and then into a rocking sieve which separates fibre and sand from the seeds, husks, and bran.

—J. H. J.

Cellulose from vegetable fibres, such as wood, cotton, straw, esparto grass, jute, and the like: Process for the extraction of —. B. Cataldi, Turin, Italy. Eng. Pat. 191,175, Sept. 11, 1916. (Appl. No. 12,862 of 1916.) Under Int. Conv., Sept. 11, 1915.

THE material, previously reduced to a suitable state of subdivision, is leached with a slightly alkaline solution; the liquid is run off and the water of "interposition" is removed as completely as possible by hydro-extractors or by treatment under vacuum or a combination of both. The fibres are then subjected to the action of chlorine gas, which is admitted under vacuum, and the slight amount of alkaline salt remaining in them neutralises any excess of hydrochloric acid which may be formed in the treatment. The chlorinated material is finally purified by a second leaching process with an alkaline solution.—J. F. B.

Paper pulp: Beating or grinding of —. E. Partington, Baron Doverdale, Westwood Park, Worcester. Eng. Pat. 110,482, Mar. 21, 1917. (Appl. No. 1276 of 1917.)

PAPER pulp is fed continuously into the first of a series of hollander beating engines, being delivered preferably near the mid-feather of the engine in front of the roll, so that it has to make the circuit of the trough several times before it reaches the outer side. From the outer side it is withdrawn and fed either by pump or by gravity to the next engine of the series, in a similar manner, and is finally discharged continuously from the last engine in a fully beaten condition.—J. F. B.

Celluloid substitute and process of making same. H. Dreyfus, Basle, Switzerland. U.S. Pat. 1,242,783, Oct. 9, 1917. Date of appl., Nov. 12, 1914.

A VISCOUS, concentrated solution of cellulose acetate is made by dissolving it in a mixture of alcohol and trichloroethylene, and the same solvent, with or without other additions, is used to produce a clear transparent substitute for celluloid.—F. Sp.

Parchmentised or vulcanised fibre: Manufacture or treatment of — and new products therefrom. J. Y. Johnson, London. From Diamond State Fibre Co., Bridgeport, Pa., U.S.A. Eng. Pat. 110,318, Dec. 11, 1916. (Appl. No. 7755 of 1917.)

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Dye content of waste liquors; Commercial process for reclaiming the —. T. Forsyth, Assignor to The Forsyth Dyeing Co., New Haven, Conn. U.S. Pat. 1,242,676, Oct. 9, 1917. Date of appl., Dec. 1, 1916.

THE dye content of waste liquors is reclaimed by adding a neutralising agent with suitable agitation, separating the sludge from the liquor, and then filtering the sludge by gravity whilst it is evaporating by atmospheric action.—F. W. A.

Waterproofing fabrics: Process of —. E. I. Cuthbertson, Vancouver, British Columbia. U.S. Pat. 1,243,327, Oct. 9, 1917. Date of appl., Nov. 22, 1916.

FABRICS are waterproofed by depositing on the fibres a film of a salt of a suitable metal, having water-repellent properties, e.g., aluminium acetate, and impregnating the film with an emulsion of wax, e.g., a mixture of vegetable and mineral wax, or of wax, oil, and resin, which combines with the aluminium acetate to form a "mineralised wax." —F. Sp.

Textile fibres and fabrics and like substances or articles; Fireproofing of —. T. J. I. Craig, and Whipp Bros. and Tod, Ltd., Manchester. Eng. Pat. 110,221, Nov. 9, 1916. (Appl. No. 15,699 of 1916.)

THE process described in Eng. Pat. 16,153 of 1914 (this J., 1915, 868) is modified in such a way that the material previously impregnated with alkali aluminate and preferably dried, is wetted with a solution of alkali bicarbonate and then treated at about 100° C. with steam or steam and carbon dioxide.—J. F. B.

Bleaching fabrics in open form: Plant for —. C. Taylor, Wilmington, Del., U.S.A. Eng. Pat. 103,647, Dec. 29, 1916. (Appl. No. 18,594 of 1916.) Under Int. Conv., Jan. 21, 1916.

SEE U.S. Pat. 1,201,388 of 1916; this J., 1916, 1216.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric and nitric acids: Distillation of mixtures of —. P. Pascal. Comptes rend., 1917, 165, 589–591.

THE thermal properties of mixtures of sulphuric and nitric acids are represented in two diagrams, using triangular co-ordinates, in which the independent variables are water, sulphuric acid, and

nitric acid. The first diagram shows the boiling points under normal pressure, and the second the concentration of nitric acid in the vapour. Three dotted curves in the second diagram (see fig.) represent the course of distillation of three different mixtures. Over a considerable area of the first diagram, ternary mixtures with a given content of sulphuric acid show a maximum boiling point, and the concentration corresponding to this maximum is displaced towards mixtures low in nitric acid as the content of sulphuric acid increases. The temperature of the maximum boiling point, after falling slightly in the region of mixtures low in sulphuric acid, rises again to about 160° C. for a mixture containing 65% of sulphuric acid, and here the maximum disappears. Diminution of pressure causes a slight increase of nitric acid in the vapours, but does not alter the general character of the phenomena. The addition of sulphuric acid to concentrated nitric acid does not at first modify to any great extent either the boiling point or the concentration of the vapour, and in fact the latter is a function of the water content over almost the entire area of the diagram. There is, however, a rapid variation in boiling point in the neighbourhood of mixtures usually employed to nitrate cotton, and according to Sapozhnikoff this would explain the relative difficulty of preparing nitrocelluloses intermediate between the collodion cottons and nitrocellulose of maximum nitrogen percentage. On the second diagram (see fig.) a curve, C.C. is shown, on the right of which mixtures on distillation will give vapours of continually decreasing concentration, while mixtures to the left of the curve (containing more water than the former) give on distillation vapours in which the concentration of nitric acid passes through a maximum. It can be shown that this maximum does not coincide with a maximum in the liquid under distillation, nor with a maximum in the distillate.—F. Sp.

Sulphur dioxide [in smelter gases, etc.]; Determination of —. O. R. Sweeney, H. E. Outcault, and J. R. Withrow. *J. Ind. Eng. Chem.*, 1917, 9, 949—950.

For the determination of sulphur dioxide in smelter gases, etc., by means of potassium permanganate, it is essential that an excess of permanganate should be present. For colorimetric comparison the best results are obtained by the use of a standard containing 10 c.c. of approximately 0.005N permanganate solution and 490 c.c. of water. After reduction of the permanganate and back titration of the solution the final colour is of a slightly redder tint than before, but by reducing and oxidising the solution several times the colour may be readily matched. About 475 c.c. of water is mixed with 30 c.c. of 2N sulphuric acid in a litre bottle, and 10 c.c. of recently standardised 0.005N permanganate solution added from a burette. After mixing, the solution is divided into two 500 c.c. bottles of uniform clear glass. Sodium sulphite solution or sulphurous acid is added to one of the bottles until the colour is very faint, after which permanganate solution is added to restore the colour, and the two solutions mixed, and again divided. The standard permanganate solution is then added from a burette in sufficient quantity not to be decolorised by the sulphur dioxide in the gas, and the contents of this bottle are introduced into a large sample bottle containing a definite volume of the gas at known temperature and pressure. After shaking this bottle for some time, its contents are run back into the small bottle, and titrated with permanganate solution until the colour matches that of the solution in the other bottle. It is then returned to the gas sample bottle, and again run back into the small bottle, and the colour matched

once more. The total amount of permanganate consumed corresponds to the sulphur dioxide in the gas:—

This method is preferable to the iodine method of titration. It gives good results in the determination of sulphur dioxide in the atmosphere.

—C. A. M.

Selenic acid; Reduction of —. E. B. Bengel. *J. Amer. Chem. Soc.*, 1917, 39, 2171—2179.

CONTRARY to the statement of Mitscherlich (*Ann. Phys.*, 1827, [i], 9, 629), selenic acid of any concentration is reduced by dry hydrogen sulphide at any temperature above -10° C. The rate of reduction increases with the temperature and concentration of the acid. Selenic acid in 10% solution at 45° C. is completely decomposed by hydrogen sulphide in 13½ hours. Sulphur dioxide reduces selenic acid in two stages, selenium dioxide being the intermediate product. When the sulphuric acid produced reaches a certain concentration, the reducing action ceases, but if the solution is diluted, the reaction proceeds to completion. Sulphur reduces anhydrous selenic acid at 65° C., but higher temperatures are necessary for aqueous solutions, e.g., a 94.2% solution is attacked at 68° C., and a 40% solution at 190° C. Selenium reduces selenic acid at ordinary temperatures, and more rapidly at higher temperatures. More concentrated solutions are more readily attacked.

—F. Sp.

Telluric acid; Reduction of —. E. B. Bengel. *J. Amer. Chem. Soc.*, 1917, 39, 2179—2183.

TELLURIC acid in aqueous solution of any concentration is slowly reduced by hydrogen sulphide and by sulphur dioxide; e.g., a 10% solution of telluric acid is completely decomposed by hydrogen sulphide in 21 hours at 115° C., and in 12 days at ordinary temperatures by sulphur dioxide. Tellurium, sulphur, and selenium also reduce solutions of telluric acid. The difficulty of reduction is greater than would be expected from a comparison of the properties of selenic acid and telluric acid, but is in agreement with Thomsen's thermochemical data.—F. Sp.

Carbonates; Studies of the —. III. Lithium, calcium, and magnesium carbonates. C. A. Seyler and P. V. Lloyd. *Chem. Soc. Trans.*, 1917, 111, 994—1001.

IN extension of the earlier investigation of the ionisation and hydrolysis of sodium carbonate and bicarbonate (this J., 1917, 453), it has been found that the ionisation of the lithium carbonates is comparable in degree with that of the corresponding sodium salts; the ionisation proceeds by the stages $\text{Li}_2\text{CO}_3 = \text{Li} + \text{LiCO}_3$ and $\text{LiCO}_3 = \text{Li} + \text{CO}_3$; the calculation of the solubility product $[\text{Li}]^2 \times [\text{CO}_3]$ for saturated solutions of lithium carbonate in water containing a varying quantity of carbonic acid, based on the supposition of the intermediate LiCO_3 ion, gives concordant values and thereby confirms the theory. The solubility product $[\text{Ca}] \times [\text{CO}_3]$ for calcium carbonate has previously been given too high a value, the figure 71.9×10^{-10} now given for 25° C. agreeing with a solubility of 14.6×10^{-5} gm.-mol. per litre, of which about 66% is hydrolysed into hydroxide and bicarbonate. On account of its tendency to decompose into basic carbonates and bicarbonate, crystalline magnesium carbonate has no definite solubility in pure water and even in very dilute solution the undecomposed salt is only very partially ionised;

the reaction approximates to the equation
 $5\text{MgCO}_3 + 2\text{H}_2\text{O} = 3\text{MgCO}_3 \cdot \text{Mg}(\text{OH})_2 + \text{Mg}(\text{HCO}_3)_2$.
 —D. F. T.

Potassium and aluminium salts: Method for the recovery of — from mineral silicates. J. C. W. Frazer, W. W. Holland, and E. Miller. Amer. Inst. Chem. Eng., June, 1917. J. Ind. Eng. Chem., 1917, 9, 935—936.

FURTHER details are given of the method outlined in U.S. Pat. 1,196,734 of 1916 (this J., 1916, 1059). The finely ground felspar is treated with about 0.8 of its weight of potassium hydroxide (or an equivalent quantity of sodium hydroxide) dissolved in a small quantity of water, and the intimate mixture is heated in an open iron vessel until the water has evaporated, and then for about an hour at 275° to 300° C. Under these conditions a reaction takes place, with the formation of a new silicate which has approximately the composition of leucite:—

The alkali may be recovered by treating the solution, from which the "artificial leucite" has been separated, with lime, and filtering off the calcium silicate, and the filtrate when evaporated may be used for the treatment of fresh portions of felspar. The loss in laboratory experiments was about 1%. For the decomposition of the insoluble silicate, as described in the patent, it is necessary to avoid a local excess of acid in the first stage of the process, since this would tend to dissolve also a portion of the aluminium, and the required quantity of dilute hydrochloric acid is therefore added gradually, and with constant stirring. The residual aluminium silicate resembles kaolinite. By treating it with an equivalent amount of sulphuric acid it is converted into aluminium silicate, whilst gelatinous silica separates. The same method of treatment is applicable to sericite and clay. The yield of potassium chloride from felspar is practically theoretical, whilst about 86% of the theoretical amount of aluminium sulphate is obtained. From a ton of felspar containing 10% of K_2O about $\frac{1}{2}$ ton of potassium chloride of 80% purity and about a ton of crystallised aluminium sulphate would be obtained. In normal times the aluminium sulphate would be more valuable than the potassium chloride; hence the importation of cheap German potash would affect the process less than if potassium chloride were the principal product. In fact under ordinary conditions the value of the process will largely depend upon whether it will yield iron-free aluminium sulphate at a lower cost than the method now used for extracting it from bauxite.—C. A. M.

Pyrolusite: Determination of available oxygen in —. O. L. Barnebey. J. Ind. Eng. Chem., 1917, 9, 961—967.

THE oxalic acid method of determining the available oxygen in pyrolusite is inaccurate, owing to the decomposition of the oxalic acid during the heating required to dissolve the ore. The decomposition is accelerated by the presence of manganese salts and by the action of sunlight. A very small amount of carbon monoxide is evolved from dilute (1.5 N) solutions of sulphuric acid containing oxalic acid, but no appreciable amount of oxygen is evolved during the inter-action of manganese dioxide and oxalic acid in dilute sulphuric acid solution. The ferrous sulphate and the direct iodometric methods (see this J., 1917, 571, 884) are free from these errors, and the following method is recommended: The well-mixed sample is ground so as to pass through a 200-mesh sieve, and dried at 105° C.

until constant in weight. 0.5 gm. is heated with 50 c.c. of standard ferrous sulphate solution (90 grms. in 200 c.c. of sulphuric acid of sp. gr. 1.84 and 900 c.c. of water) until dissolved, the solution diluted to about 150 c.c., and the excess of ferrous iron titrated with standard permanganate solution.—C. A. M.

Hydrogen sulphide: Influence of added substances on the iodometric titration of —. A. R. Jayson and R. E. Oesper. J. Ind. Eng. Chem., 1917, 9, 975—977.

THE red coloration which appears during the iodometric titration of hydrogen sulphide in acid solution appears to be due to acid hydrolysis of the starch to erythro-dextrin, which is accelerated by hydrogen sulphide in the presence of iodine. The amount of erythro-dextrin formed, as judged by the depth of the red coloration, depends upon the quantity of acid present, and increases with the concentration of the acid. At the end of the titration erythro-dextrin is no longer formed, but blue starch iodide, and a mixture of the latter with the red erythro-dextrin iodide, would give a purple end coloration. Reduction of the concentration of the acid beyond a certain limit is not practicable in the titration of cadmium sulphide precipitates, owing to the rate of solution being too slow. The end-point is not rendered more definite by the addition of various salts.

C. A. M.

Handling and transportation of liquids. Eisenhart. See I.

PATENTS.

Phosphoric acid and compounds of the same; Apparatus for manufacture of —. W. H. Waggaman, H. Bryan, and C. R. Wagner. Washington, D.C. U.S. Pat. 1,241,791, Oct. 2, 1917. Date of appl., Mar. 16, 1917. (Dedicated to the public.)

A BLAST furnace for producing phosphoric acid comprises an inner chamber for the charge which discharges upon a platform built at the bottom of an outer annular chamber. Tuyères are provided, one set to cause a blast of air to burn and oxidise the charge on the platform, and another set to introduce air into the upper part of the annular space to complete the oxidation of volatile products.—H. J. H.

Nitre cake: Treatment of —. J. Grossmann, Manchester. Eng. Pat. 110,405, Oct. 20, 1916. (Appl. No. 14,922 of 1916.)

NITRE cake is converted into a friable mass, suitable for crushing or grinding, by mixing it in the molten state with about 5% of sodium carbonate, or with sodium carbonate and a "diluent" such as sodium sulphate, and then chilling the mass, e.g., with water, salt solution, glycerin, etc.—F. Sp.

Nitrosic [nitrous] gases: Process of producing —. W. S. Landis, Niagara Falls, N.Y., Assignor to F. S. Washburn, Nashville, Tenn. U.S. Pat. 1,242,953, Oct. 16, 1917. Date of appl., Feb. 20, 1915.

NITROUS gases are produced by passing a mixture of ammonia, oxygen, and air, containing sufficient oxygen to sustain the reaction, e.g., above 30%, but not enough to cause substantial decomposition of the ammonia, through a hot catalyst at constant pressure.—F. Sp.

Oxidising gases: Process of —. Apparatus for oxidising gases. [Preparation of phosphoric acid.] F. C. Schmitz, New York. U.S. Pats. (A) 1,242,987 and (B) 1,242,988, Oct. 16, 1917. Date of appl., (A) Jan. 22, and (B) Oct. 21, 1914.

(A) GASES are oxidised by passing them through

a chamber in a zigzag path, and subjecting them to the action of oxygen passing in the opposite direction. In particular, phosphoric acid is prepared by fusing a mixture of phosphate rock, silica, and carbon, driving off the phosphorus as vapour, oxidising it to phosphorus pentoxide by a counter-current of oxygen, and absorbing the phosphorus pentoxide in a dilute solution of phosphoric acid. (B) A plant for carrying out the process described in (A) consists of an electric furnace, connected by a flue with an oxidising chamber into which oxygen can be introduced in a direction contrary to that of the phosphorus vapour, and an absorption tower.—F. Sp.

Calcium and magnesium; Method of separating—in saline solutions. C. Glaser, Baltimore, Md. U.S. Pat. 1,242,434, Oct. 9, 1917. Date of appl., Oct. 8, 1914.

MAGNESIUM and calcium salts contained in a saline solution are separated from it and from each other by adding a sufficient quantity of sodium carbonate to convert them into carbonates, allowing calcium carbonate to precipitate at a temperature not above 60° C., separating the supernatant liquor, and either precipitating the magnesium as carbonate by heating the liquor to 70°–103° C., or as a slightly basic carbonate by adding a small quantity of caustic soda and heating to 70°–103° C.—F. Sp.

Barium oxide; Process of making——. J. G. Kremers, Milwaukee, Wis. U.S. Pat. 1,243,190, Oct. 16, 1917. Date of appl., Dec. 6, 1915.

BARIUM oxide is produced by heating to a high temperature in a muffle furnace dried briquettes of a mixture of barium carbonate and carbon. The chamber of the furnace may be previously filled with an atmosphere of carbon monoxide, e.g., by introducing carbon alone under suitable conditions.—F. Sp.

Nitrogen compounds; Process for forming——. L. Summers, Chicago, Ill. U.S. Pat. 1,242,264, Oct. 9, 1917. Date of appl., Apr. 22, 1914.

A MIXTURE of manganiferous and carbonaceous material is heated, and gases containing nitrogen are drawn through the mass. Volatile nitrogen compounds are produced and condensed.—F. Sp.

Aluminium nitride; Process for producing——. H. L. Duncan, Mahwah, N.J. U.S. Pat. 1,241,834, Oct. 2, 1917. Date of appl., Oct. 12, 1916.

A CHARGE of carbonaceous and aluminous material is fed into a revolving inclined cylindrical furnace, and is heated by the injection with compressed air in an axial direction of a stream of luminous flame producer gas. At the same time the charge at the lower end of the furnace is maintained under a nitrogenous reducing atmosphere by a jet of hot producer gas which impinges upon it. This leads to nitride formation, and at the same time prevents contact of the heating flame with the walls of the furnace. The combustible gases from the furnace are used to preheat the charge in a second furnace.—H. J. H.

Elements [silicon] from their compounds; Process of securing——. V. M. Weaver, Harrisburg, Pa., Assignor to The Weaver Co. U.S. Pat. 1,241,796, Oct. 2, 1917. Date of appl., Jan. 14, 1915.

THE process consists in feeding a compound of an element, e.g., silicon chloride, into a bath of molten metal, e.g., aluminium, whereby the compound in rising through the melt is decomposed, and the element, i.e., silicon, set free, a metallic chloride being formed.—H. J. H.

Ammonia; Producing——. C. Bosch, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,243,382, Oct. 16, 1917. Date of appl., Jan. 12, 1914. SEE Fr. Pat. 466,303 of 1913; this J., 1914, 645.

Apparatus for use in concentration of vitriol or other liquors. Eng. Pat. 110,183. See I.

Process of filtering. U.S. Pat. 1,242,355. See I.

Acid-resisting cement. Eng. Pat. 110,258. See IX.

VIII.—GLASS; CERAMICS.

Iron; Determination of—in glass sand. J. B. Ferguson. J. Ind. Eng. Chem., 1917, 9, 941–943.

FIVE grms. of the sand is moistened with 5 c.c. of dilute (1:1) sulphuric acid in a platinum basin, and evaporated with 40 c.c. of hydrofluoric acid until fumes of sulphur trioxide appear. If, after cooling, any silica can be seen, the process is repeated once or twice, and the temperature then raised until all hydrofluoric acid has been driven off, and copious fumes of sulphur trioxide arise. The vessel is then cooled, and its contents diluted with water and filtered. The residue on the filter, which may contain black carbonaceous particles derived from the ceresin bottle in which the hydrofluoric acid was kept, is dried and ignited in a platinum crucible, and the residue from the ignition fused with iron-free potassium pyrosulphate. The melt is dissolved in dilute sulphuric acid, and the solution added to the filtrate and washings. If a residue of black particles remains, as will be the case if staurolite is present, it is filtered off, ignited, and fused with sodium carbonate. The melt, which should now be free from black particles, is treated with dilute sulphuric acid and the solution filtered from insoluble sulphates, and added to the two previous filtrates. The iron may then be determined in the united filtrates, preferably by reduction with stannous chloride and titration with potassium bichromate.—C. A. M.

Glass; Relation between the physical properties and chemical composition of——. VII. Etch figures. E. W. Tillotson, jun. J. Ind. Eng. Chem., 1917, 9, 937–941.

THE so-called crystalline "etch figures" which are formed when glass is treated with hydrofluoric acid, with or without the addition of soluble fluorides, have been attributed to pre-existing crystals in the glass. The results of experiments here described show that all glasses dissolve uniformly in acid fluoride solutions, and that the formation of matt etches and etch figures is due to the production of insoluble substances which are in contact with the surface and prevent it from dissolving at those points. The solution of the glass and the growth of insoluble crystals take place simultaneously. When the etching solution is acid ammonium fluoride the protective crystals consist of ammonium silicofluoride. In the case of solutions containing potassium salts, characteristic etch figures are produced irrespective of the composition of the glass.—C. A. M.

PATENTS.

Hollow glass ware; Manufacture of—and apparatus therefor. L. N. Bruner, Zürich, Switzerland, and S. D. Olsen, Leeds, Eng. Pat. 110,390, Oct. 17, 1916. (Appl. No. 14,741 of 1916.)

MOLTEN glass flows into a cup inside a rotary

mould and is supplied to the latter by centrifugal action when the cup is rotated rapidly. The cup may be raised automatically above the top of the mould to receive the glass and it may afterwards be lowered gradually so as to coat the mould uniformly. The mould may be fitted with a cap, locked by centrifugally acting balls, which also serves to shape the upper edge of the glass article. On again raising the cup the glass article is discharged from the mould. A series of these moulds may be arranged on a table with a step-by-step action, so that they are used successively. —A. B. S.

[Sheet] glass manufacture. A. A. Ileenhour, Arnold, Pa., Assignor to Pittsburgh Plate Glass Co., and C. R. Sammons, Pittsburgh, Pa., L. K. Guiler, B. H. Thompson, S. A. Gilmore, and A. E. Sixsmith. U.S. Pat. 1,242,441, Oct. 9, 1917. Date of appl., Feb. 19, 1911.

A PORTION of a bath of molten glass is isolated and its temperature reduced by surrounding it by a hollow refractory body, so that it forms the edge of a sheet of glass which is to be drawn from the bath. The temperature of each edge is regulated by adjusting the depth of immersion of either end of the refractory body, and the sheet of glass is then drawn.—W. F. F.

Tunnel dryer for drying bricks, retorts, and the like. J. T. and W. J. Price, Dudley, Eng. Pat. 110,531, Aug. 2, 1917. (Appl. No. 11,124 of 1917.)

IN a tunnel dryer, straight and winding longitudinal flues at each side of the furnace extend partly along each side of the tunnel, opening at one end into the tunnel and at the other to the atmosphere. Similar flues are connected to chequered flues built above the furnace. The lengths of the respective flues are adjusted to the requirements, the object being to distribute hot air uniformly throughout the tunnel.—A. B. S.

IX.—BUILDING MATERIALS.

Tricalcium aluminate: Formation of — [in Portland cement]. E. D. Campbell. J. Ind. Eng. Chem., 1917, 9, 943—946.

LE CHATELIER concluded that the two essential constituents of Portland cement are tricalcium silicate and tricalcium aluminate, but free lime is always present in cements prepared in accordance with his formula, and this is also the case with products made in accordance with the formula of Newberry, who concluded that the essential constituents are dicalcium aluminate and tricalcium silicate. Practically pure tricalcium aluminate was prepared by Shepherd, Rankin, and Wright (this J., 1909, 1124), whilst the author obtained crystals of practically pure tricalcium silicate by slowly cooling a solution of dicalcium silicate and calcium oxide in $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ (this J., 1914, 964). Further experiments are now described which support the view that tricalcium aluminate should be regarded as either a saturated solid solution of CaO in $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$, or as $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ with 4 mols. of CaO of crystallisation, rather than as a definite phase stable at all temperatures up to 1535°C .—C. A. M.

Magnesia; Refractory properties of—, H. Le Chatelier and B. Bogitch. Comptes rend., 1917, 165, 488—491.

MEASUREMENTS of the crushing strengths at different temperatures have been made on a

number of commercial magnesia bricks and specimens prepared in the laboratory. Tests were also made on a chrome brick as these form the separating course between the basic hearth and the acidic arch of steel furnaces. The seven specimens were:—I. Styrian brick (made in 1890) fired at 1450°C , normal quality. II. Euboean brick made in 1910. III. Brick of good present-day manufacture. IV. Brick of medium quality; 3% of pyrites cinder added in the making. V. Pure precipitated magnesia fused in electric furnace and thereby contaminated. VI. Raw material of No. IV agglomerated in electric furnace. VII. Chrome brick.

Percentage composition.

	I.	II.	III.	IV.	V.	VI.	VII.
MgO	86.7	93.4	89.4	81.2	93.7	88.5	12.3
CaO	1.0	3.7	4.5	4.8	2.7	4.5	5.8
Fe ₂ O ₃	6.0	0.5	1.1	4.2	0.3	1.4	15.5
Al ₂ O ₃	0.6	0.2	0.8	1.0	1.1	0.6	10.9
SiO ₂	6.7	2.8	4.2	8.8	3.2	6.5	4.7
Cr ₂ O ₃	—	—	—	—	—	—	50.0
MnO	—	—	—	—	—	—	1.5
	101.0	100.6	100.0	100.0	101.0	100.9	100.7

Crushing strength in kilos. per sq. cm.

	15° C.	1000° C.	1300° C.	1500° C.	1600° C.
I.	145	85	66	3.6	1.8
II.	420	—	—	185	8
III.	390	—	—	90	4.8
IV.	230	—	—	16	3.5
V.	—	—	—	90	6.6
VI.	530	—	—	—	3.5
VII.	260	120	6	2	1

The results show that there is a sudden breakdown of crushing strength at 1500°C — 1600°C . for the purer brick II. and at 1300°C — 1400°C . for the less pure Styrian brick, although these temperatures are far below the fusion temperatures of magnesia or of the brick mixtures. Apparently the more fusible binding material melts, leaving the grains of magnesia in a condition analogous to that of wet sand and with only a very small crushing strength. Thus at 1600°C . the best magnesia bricks have a strength in compression distinctly less than silica which is much nearer its melting point. Chrome brick behaves like the magnesia bricks but the temperature of collapse is still lower, viz., about 1100°C .—H. J. H.

Magnesia; Refractory — [for furnace linings]. R. C. Gosrow. Met. and Chem. Eng., 1917, 17, 415—417.

THE author records experience in the manufacture of linings of magnesia from Californian magnesite of composition: MgCO_3 , 98.10%; CaCO_3 , traces; Al_2O_3 and Fe_2O_3 , 0.90%; insoluble, 0.50%. This was calcined in an oil-fired shaft furnace after being broken down to lumps of $1\frac{1}{2}$ —3 in. size. The product had the composition: MgO , 91.7%; CaO , 0.10; Fe_2O_3 and Al_2O_3 , 1.9%; insoluble, 0.85%; loss on ignition, 2.2%. It was reduced to $\frac{1}{4}$ in. size and heated in the crucible of a Stassano electric furnace until it was partly fused. The product on cooling showed a loss on ignition of 0.7%, was hard enough to scratch glass, and did not increase in weight on exposure to moist air for 10 days. Before treatment in the electric furnace the material increased in weight 6% in 172 hours. The dead-burnt product was ground to pass a 6-mesh sieve and mixed with 10% of powdered (80-mesh) ferrie oxide, 5% of basic steel furnace slag, and about 12% of well boiled tar. The mixture was rammed

round a steel plate form so as to make the lining of a Stassano furnace in one piece in position. The author claims to have had considerable success in the use of such linings for furnaces for ferro-alloys, tungsten, molybdenum, and manganese. In making these linings it is desirable to use material containing only small percentages of iron and to use a binder other than tar. Rapid heating of the lining and the use of comparatively thin lining walls also appear necessary to success.

—H. J. H.

Heat-insulating value of roofing materials. W. M. Thornton. Engineering, 1917, 104, 405—406.

EXPERIMENTS at the National Physical Laboratory have shown that the loss of heat by a room is more influenced by the rate of emission of the surface than by the rate of conduction of heat through the material of the walls. This is confirmed by the author's measurements of the heat-insulating properties of roofing materials. The rate of rise of temperature inside a box-shaped chamber with walls of efficient heat-insulating

ciently quickly to be employed for ordinary building purposes and is not too sticky to be worked with a trowel, is made by adding 0.5—5% of plaster of Paris or calcium sulphate to a silicious acid-resisting cement of the customary type. Suggested proportions are: Ground stoneware passing through a No. 30 sieve 8 parts, fine Leighton sand 7 parts, ground blue brick passing through a No. 60 sieve 2 parts, sodium silicate solution at 55°—65° F. (sp. gr. 1.275—1.325) 3 parts, and plaster of Paris 0.12 part, all by weight. The solids are first mixed intimately together and the silicate solution is then incorporated, preferably by treating the material for 5—10 mins. in an edge runner mill. The cement should be used within an hour of its production and the finished work should be heated to 100° C. for several days, or to a higher temperature for a shorter time. These cements are stated not to be affected by mineral acids over a wide range of temperature nor by sulphur dioxide or trioxide, nitrous gases, chlorine, or hydrogen sulphide.

—A. B. S.

Material.	Rise of temperature in testing chamber. °C. per minute.	British thermal units per 100 sq. ft. per hour.	Thickness in inches.	Weight in pounds per square foot.

material was measured, when the top—which could be of any desired material—was exposed to the radiation from an electrically heated surface, of intensity equal to that of bright direct sunlight. The results given in the table show that the emissivity of the surface is the dominant factor and not the conductivity of the material.—H. J. H.

PATENTS.

Sound absorbing material for walls and ceilings. W. C. Sabine, Boston, Mass., and R. Guastavino, Long Island, N.Y., U.S.A. Eng. Pat. 110,194, Oct. 12, 1916. (Appl. No. 14,534 of 1916.)

A POROUS sound-absorbing material is made of particles of sand or like material graded to an approximately uniform size, which will pass through a No. 12 sieve, so that when bonded the interstices between the particles will absorb in excess of 15% of sounds lying between middle C and the third octave above middle C, i.e., the characteristic sounds of articulate speech. The bond suggested is Portland cement. A composite material composed of layers in which the particles are of different sizes may be used to absorb sounds of both low and high pitch; coarse particles are preferable for the former and fine ones for the latter.—A. B. S.

Acid-resisting cement. Chance and Hunt, Ltd., A. E. Holley, and H. W. Webb, Oldbury, Eng. Pat. 110,258, Jan. 20, 1917. (Appl. No. 1024 of 1917.)

A CEMENT which, while resisting acid, sets suffi-

Cement. L. McCulloch, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,241,531, Oct. 2, 1917. Date of appl., Jan. 7, 1914.

A CEMENT which contracts on setting, is made by mixing magnesium oxychloride with the product of the reaction of sugar and an alkaline substance, e.g., lime.—H. J. H.

Plastic article: Composite—, and process of producing the same. H. W. Charlton, Jones Point, N.Y. U.S. Pats. (A) 1,242,421 and (B) 1,242,422, Oct. 9, 1917. Date of appl., May 22, 1917.

(A) A PLASTIC composition or cement is formed by mixing an insoluble residue obtained from greensand calcined to give it an ochre colour, and an insoluble residue obtained from feldspar. Both residues are obtained as a result of digestion processes. The composition is moulded and treated with steam under pressure. (B) Material containing silicon and aluminium is digested with lime at a temperature and pressure and for a time sufficient to form a compound containing calcium, silicon, and aluminium. Bricks are made by mixing sand with the above as a binding material.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Ferro-silicon: Method for the commercial analysis of —. R. E. Lowe, Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 6 pages.

DECOMPOSITION and solution of the finely divided

(100-mesh) sample is effected by heating 1 gm. on a water-bath with 25 c.c. of concentrated nitric acid, in a platinum dish, and adding hydrofluoric acid, a few drops at a time, until no further violent reaction occurs and only a slight insoluble residue remains. Another 5 c.c. of hydrofluoric acid is then added and the solution evaporated to dryness. For the determination of sulphur and phosphorus, the residue is dissolved in 10 c.c. of nitric acid, again evaporated to dryness, and finally dissolved in 50 c.c. of 5% nitric acid. After neutralisation with sodium carbonate, the mixture is diluted, heated, allowed to settle, and filtered. The filtrate now contains the sulphur, with a small amount of sodium fluoride, and the precipitate the phosphorus as iron phosphate. The solution is treated with a slight excess of calcium chloride, the precipitated calcium carbonate and fluoride filtered off, and the filtrate acidified and treated with barium chloride as usual. The sodium carbonate precipitate is dissolved on the filter with nitric acid (1:3) and the solution boiled for 5 mins. with a few drops of strong potassium permanganate solution, after which any manganese dioxide present is dissolved by the addition of a solution of ferrous sulphate in dilute sulphuric acid; the clear liquid is then treated with ammonium molybdate as usual. Manganese, iron, and aluminium are determined in a fresh portion of the sample by the usual methods: solution is effected as above, except that the residue from the first evaporation is dissolved in sulphuric acid (1:5), the solution evaporated nearly to dryness (to expel all hydrofluoric acid), and then boiled with water containing a little hydrochloric acid. Silicon is determined by difference. The method gives results in close agreement with those obtained by fusion with alkali carbonate and nitrate, but is much more rapid and convenient than the latter and less destructive of platinum.—W. E. F. P.

[Steel] fence wire: *Corrosion of* —. O. W. Storey. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 28 pages.

FROM the examination of numerous samples before and after service, it is concluded that the life of fence wire depends both on the quality of the iron or steel base and on the galvanising. Zinc corrodes more slowly under conditions favouring the rapid corrosion of iron, and *vice versa*; and as the galvanising is usually thin, the iron or steel base should be highly resistant. As shown by the greater durability of the older steel fence wire, copper is a strong protective against corrosion, steel fence wire containing copper being as durable as wrought iron; modern wire usually contains no copper and corrodes rapidly. Manganese has no influence on the durability under the conditions of service.—W. E. F. P.

"Stellite" as a substitute for platinum. E. Haynes. J. Ind. Eng. Chem., 1917, 9, 974—975.

"STELLITE" alloys consist, in the main, of cobalt and chromium, the proportion of the latter in the malleable alloys ranging from about 10 to 50%. They are all hard and cannot be worked by machine, although the softer ones can be drilled. They resist nitric acid, even when boiling, but are slowly attacked by hydrochloric, sulphuric, and hydrofluoric acids. They are not attacked by fruit acids, and evaporating dishes made from them are particularly suitable for evaporating solutions of salts or boiling caustic alkali solutions. They are forged with difficulty at temperatures from 750° to 1200° C., and vessels composed of them can be heated to 1200° C., and still retain considerable strength. They are unaffected by hydrogen sulphide or ammonium chloride vapours. When heated to redness they

become coated with a blue-black film, which does not change in weight or appearance after repeated heating. These alloys are also suitable substitutes for platinum in jewellery.—C. A. M.

Lead in copper: *Spectroscopic determination of small amounts of* —. C. W. Hill and G. P. Luckey. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 6 pages.

THE authors describe a method for the determination of small quantities of lead in copper, which is sufficiently reliable for use in the copper refinery. A known weight of the sample is placed in a slight cavity in a positive, graphite electrode, above which a fixed or rotating negative electrode of carbon is used; the spectrum is observed through a grating spectroscope, and the time required for the disappearance (or definite enfeeblement) of the bright lead line in the spectrum is measured with a stop-watch. With a carefully regulated arc, the times vary regularly with the weight of copper used and the lead content of the sample, e.g., from 14 secs. with 0.2 gm. of copper containing 0.001% Pb to 277 secs. with 1 gm. of copper containing 0.038% Pb.—W. E. F. P.

Metals: *Corrosion of* — by acids. O. P. Watts and N. D. Whipple. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 24 pages.

FROM a study of the electrochemical principles involved in the corrosion of representative metals by acid and other solutions, it is concluded that all metals may be classified according as their potentials are greater or less than the discharge potentials of hydrogen on them. Metals of the first class dissolve readily in acids, but those of the second only dissolve readily when oxidising agents are also present; the superiority of nitric acid over other acids as a general solvent for metals is due to its oxidising power. The protective effect of arsenic in the corrosion of iron by sulphuric acid is due to polarisation by hydrogen; amalgamation protects zinc from corrosion by acids because the discharge potential of hydrogen on mercury exceeds the potential of zinc. The corrosion of metals of which solution is hindered by a polarising film of hydrogen is not accelerated by a vacuum, as is frequently stated, but retarded by the removal of atmospheric oxygen, which has a depolarising effect. The above classification is also applicable to the dissolving of any metal in any electrolyte from which hydrogen is displaced during solution, and to the electrodeposition of metals generally.—W. E. F. P.

PATENTS.

Pig-iron: *Making* —. E. Humbert, Welland. Ont., Canada. U.S. Pat. 1,212,142, Oct. 9, 1917. Date of appl. May 17, 1917.

AN electric furnace is fed with a charge containing ferrous scrap which contains less carbon and little more phosphorus than are required in the pig iron, and a carbonaceous material. The charge is heated and air is simultaneously injected into the solid portion of the charge to combine

with the carbon. When the charge is melted the air supply is stopped, and manganese, silicon, or like material is added as desired.—W. F. F.

Furnaces; Electric heating and [steel] melting——
V. Stobie, Dunston-on-Tyne, Durham, Eng. Pat. 110,409, Oct. 26, 1916. (Appl. No. 15,242 of 1916.)

To reduce the consumption of carbon electrodes in steel melting furnaces, a portion of the electrode, outside the furnace chamber, is surrounded by a chamber, which is practically continuous from the electrode hole in the roof to a point along the electrode where the temperature is below the combustion temperature of carbon. The chamber may be of brick or cast iron, and of a definite or variable length, and is closed above by a sealing gland.—B. N.

Castings ingots of metals and alloys; Apparatus for——
P. H. G. Durville, Paris, Eng. Pat. 105,075, Mar. 21, 1917. (Appl. No. 4125 of 1917.) Under Int. Conv., Mar. 21, 1917. Addition to Eng. Pat. 23,719 of 1913 (this J., 1914, 699).

AN ingot mould with a separate upper part lined with refractory material, has also a layer of refractory material on its bottom to retard cooling and solidification. By means of a core secured in the centre of the mould, hollow ingots may be cast, also reinforced ingots by using an internal metallic core. On top of the upper part of the mould is a pocket in which the crucible to contain the molten metal is fixed by wedges; trunnions on each side of the mould support it on a rigid stand, and enable the whole to be inverted.—T. H. B.

Alloy castings; Process of making——
W. McA. Johnson, Assignor to The Continuous Zinc Furnace Co., Hartford, Conn. U.S. Pat. 1,243,416, Oct. 16, 1916. Date of appl., Mar. 3, 1914.

THE constituent metals of the alloy, one of which is a volatile metal, are melted and refined separately and transferred in a molten state, in suitable proportions, into a closed electric furnace, where the mixture is stirred mechanically and further heated to obtain a homogeneous alloy.—T. H. B.

Electric welding; Process of uniting similar or dissimilar metals or alloys by——
H. L. T. Wolfe, Jamalpur, India. Eng. Pat. 110,214, Oct. 26, 1916. (Appl. No. 15,252 of 1916.)

THE piece to be welded is inserted in a slot or recess in the body of metal, and air is excluded from the surfaces by caulking the edges of the slot. The whole is then subjected to a gradually increasing pressure and an electric heating current, the latter being passed through the body of metal. The protruding edges of the inserted piece are thus spread over beyond the caulked edges, and the exclusion of air is further ensured, the current being then increased to bring the surfaces to a welding temperature. The inserted piece may, if necessary, be completely enveloped in a thin sheet of copper or other suitable metallic substance to facilitate the welding.—B. N.

Metals; Apparatus for the electro-deposition of——
F. R. Tubbs, Birmingham. Eng. Pat. 110,248, Dec. 21, 1916. (Appl. No. 18,287 of 1916.)

THE articles to be plated are contained in a perforated barrel having its ends and cylindrical part made of celluloid, or having wood ends covered on the inner, or both inner and outer, sides as well as on the edges, with celluloid. The cylindrical portion of the barrel is cemented to the celluloid, or celluloid-covered ends, so as to obviate crevices in the interior of the barrel, and dispense with the use of metallic screws or the like. The barrel

may be provided with internal ribs of celluloid which may be cemented to the interior or moulded in one piece with the cylindrical portion. The metallic contacts on the inner sides of the ends are accommodated in recesses, and secured in place by non-metallic fastenings. Tubular pivots, to receive the ends of the rotating shafts, are attached to the metallic contacts, and arranged so that their common axis is inclined to that of the barrel. The shafts are made hollow and are provided with copper or other like electrical conducting cores connected to the metallic contacts. Electrical connection is made with brasses, or bushes, in which the shafts rotate, through radial pins in the shafts, and the bushes are connected to suitable leads. The mouth of the barrel is provided with a sliding lid or cover, and with non-metallic fastenings for securing the lid in a closed position.—B. N.

Electroplating apparatus. L. Potthoff, Flushing, N.Y. U.S. Pat. 1,243,098, Oct. 16, 1917. Date of appl., Feb. 11, 1916.

IN an apparatus for electroplating tubular articles, non-conducting plugs are inserted at the ends of the articles and a conductor attached to the article passes through the plug. These conductors support the articles on rails in the plating bath, and an endless conveyor with projecting teeth moves them in succession along the rails.—W. F. F.

Copper tubes; Method and apparatus for electrically making——
E. Emerson, Auburn, R.I. U.S. Pat. 1,243,274, Oct. 16, 1917. Date of appl., Jan. 26, 1917.

COPPER tubes are made by depositing copper electrolytically on a core of lead which has been bent into the form of a circle and its ends secured. The core is subsequently cut and removed by melting. The vat carries a pair of parallel longitudinal conducting bars at the top on each side, the two outer bars being connected by semi-circular strips depending into the vat and the two inner bars by similar concentric strips. The strips support longitudinal bars which act as anodes, and the circular lead core is rotated between and concentrically with the semi-circular strips. The core is supported by three parallel grooved rotating rollers above the vat, and is guided by two guide bars within the vat between the anodes. The electric circuit is completed through the core and one of the supporting rollers.—W. F. F.

Smelting furnaces or cupolas. A. Poulson, Hough Green, and W. C. A. Mate, Garstang. Eng. Pat. 110,283, Mar. 6, 1917. (Appl. No. 3275 of 1917.)

THE blast is led tangentially to an annular chamber surrounding the cupola and from this chamber tangential tuyère holes communicate with the furnace. The blast inlet is surrounded by a heating jacket into which a portion of the hot gases from the cupola is led.—T. H. B.

Metallurgical furnace; Electric——and method of operating the same. W. E. Moore, Pittsburgh, Pa. U.S. Pat. 1,242,464, Oct. 9, 1917. Date of appl., Nov. 27, 1916.

IN the manufacture of steel or other metal in an electric furnace of the arc type, the current is passed through a number of electrodes in series with the metal to melt it, and then through the electrodes in parallel and through a slag and the metal for refining. The current through the metal may be varied by varying the lengths of one or more of the arcs. The current may be supplied by a transformer in which the primaries are connected delta and the secondaries in star for melting the metal, and the primaries connected

in star and the secondaries in delta for refining the metal. Subsections of the primary or secondary or both may be connected in series or multiple to vary the voltage between the melting and refining operations. The melting pot may have a conducting bottom, and three arcing electrodes supplied from a three-phase transformer may be used, means being provided to change the transformer windings from delta to star or *vice versa*.—W. P. F.

Roasting-furnace. A. W. Livingston, Oakland, Cal. U.S. Pat. 1,242,455, Oct. 9, 1917. Date of appl., May 22, 1915.

A FURNACE for continuously roasting ores containing vaporisable constituents has one or more vertical roasting chambers of relatively small diameter and narrower at the top than at the bottom to contain a thin layer of ore, a source of heat on one side and a suction chamber on the other side of each roasting chamber, and connected with them by flues in the walls. Means are provided whereby the ore can be continuously introduced and withdrawn.—T. H. B.

Annealing, case-hardening, fusing and similar processes; Furnace for—. F. J. Grocott, Edgbaston, Eng. Pat. 110,443, Dec. 7, 1916. (Appl. No. 17,551 of 1916.)

A FURNACE of horizontal type is heated by gaseous fuel from a producer which is built as part of the furnace. By the opening or closing of certain passages by dampers the furnace may be used with an oxidising or non-oxidising flame or as a box muffle. The horizontal oven of the furnace is built immediately above a combustion chamber running the full length and breadth of the oven, the chamber being placed immediately over a gas arch, having gas openings in the crown and surrounded by curved air flues. The combustion chamber communicates with the oven by passages extending at the back and both sides of it, and with the top flue to the chimney by passages, some of which extend directly to the top flue over the oven arch; there are also passages leading from the oven into the top flue.

—T. H. B.

Cementing and hardening metal objects; Process for— and oven for carrying out this process. E. Schraner, Zürich, Switzerland. Eng. Pat. 110,465, Feb. 10, 1917. (Appl. No. 2057 of 1917.)

A LAYER of substances such as common salt, potassium nitrate, barium carbonate, compounds of ammonia, lead, etc. which fuse and evolve reducing fumes at the temperature employed, is passed in the hardening chamber on a tray supported above the bottom and formed of adjacent parallel bars. The substance melts and falls into the bottom of the chamber. A layer of the cement material (bones, leather, etc.) is now placed on the tray, the articles to be hardened are embedded in this, and the whole is covered by a top layer containing iron and silicates (e.g., a mixture of iron filings, powdered glass, and sand).

—T. H. B.

Copper and other metals; Apparatus for electrolytic production of—. M. V. Garin, Paris. Eng. Pat. 110,474, Mar. 2, 1917. (Appl. No. 3125 of 1917.)

ELECTROLYTIC apparatus, for the production of copper, nickel, gold, silver, or other metals, is provided with one or more cathode discs mounted on a horizontal shaft, and arranged to rotate opposite one or more circular, semi- or part-circular, insoluble anodes. A sloping or truncated conical surface is presented by each anode to the corresponding cathode, so that the strength

of the current at each point of the cathode or cathodes is proportional to the speed of movement of the cathode surface. A vertical gap is provided in the anode to enable the cathodes and the shaft or shafts to be removed without interfering with the fixed anodes. The cathodes may be of sloping or truncated conical form, in which case the anodes have a plane surface, and diaphragms are placed between the anodes and cathodes. Brushes, rubbers, or wipers of any kind, may be either fixed or receive a special movement for smoothing the surface of the deposit on the rotating cathode discs, thus removing bubbles of hydrogen and producing compact deposits.—B. N.

Distilling apparatus; Electrical—. *Process and apparatus for distilling metallic ores and metal-bearing materials. Electric furnace.* (A) and (D), C. H. Fulton, St. Louis, Mo., Assignor to Metallurgical Laboratories Incorp., Chicago, Ill. (B) and (C), C. H. Fulton and T. M. Bains, jun., St. Louis, Mo., Assignors to Metallurgical Laboratories, Incorp., Chicago, Ill. U.S. Pats. (A) 1,242,337, (B) 1,242,339, (C) 1,242,340, and (D) 1,242,341, Oct. 9, 1917. Dates of appl., Dec. 7, 1916, Jan. 24, Mar. 16, and Feb. 23, 1917.

(A) FINELY divided ore or metal-bearing material is mixed with a suitable reducing agent and moulded into cellular form. The moulded structure is placed between electric conductors in a furnace and forms a continuous resistance without change of form or volume. The distillate passes to a condenser which may be heated to any desired temperature by a heating medium, which may also heat the furnace before distillation commences to reduce the consumption of electrical energy. (B) Metallic ore or metal-bearing material is formed into briquettes which retain their original form and volume when distilled, and the briquettes are fed continuously into the distillation chamber of an electric furnace so that they form a resistance between the electrodes while passing through. (C) The furnace comprises a vertical annular chamber divided into a number of vertical distilling chambers through each of which a column of briquettes containing the metal is fed by feeding devices controlled independently. The briquettes pass through an opening in an electrode, and separate means are provided for making electrical contact between the column and the electrode. (D) In an electric furnace for use as in (A), (B), and (C), the two conducting elements are arranged substantially at right angles. An extension on one element projects into an opening in the other of such size that angular movement may take place without binding. The two elements are connected by a granular conducting material composed of finely divided graphite, 60%, and pitch, 40%.—W. F. F.

Tinning metal plates and other articles; Process of—. C. Dreymann, Baltimore, Md. U.S. Pat. 1,242,532, Oct. 9, 1917. Date of appl., May 15, 1916.

THE plate is passed through a bath of molten tin, and out through a layer consisting essentially of an ester of a saturated fatty acid, e.g., hydrogenated oil.—T. H. B.

Smelting process and apparatus. E. A. Mathers, New York. U.S. Pat. 1,242,833, Oct. 9, 1917. Date of appl., Dec. 20, 1911.

A CONTINUOUS stream of pulverised ore is fed into a closed electric furnace, where it falls successively on a series of heating bodies placed stepwise. Air under pressure is forced into the furnace between the heating bodies in a direction approximately parallel with the stream of ore. The air

and gaseous products of combustion are kept in constant circulation through the furnace and parts communicating with it.—T. H. B.

Amalgams; Process for making—A. I. Halvorsen, Perth Amboy, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,243,062, Oct. 16, 1917. Date of appl., Dec. 30, 1915.

A THIN film of mercury, continuously rotating horizontally, is brought into contact with a body of metal which is continuously rotating vertically. A continuous cycle is maintained by removing the amalgam, freeing it from the metal, and returning the mercury to take up more metal.—T. H. B.

Ores; Apparatus for treating—A. J. Garver, Clarkston, Wash. U.S. Pat. 1,243,505, Oct. 16, 1917. Date of appl., Dec. 8, 1914. Renewed Mar. 13, 1917.

THE ore is passed down a shoot in which it is mixed with a suitable chemical and heated by the products of combustion from a furnace below the shoot. The hot mixture falls into a horizontal cylindrical rotary roaster, the wall of which is provided with longitudinal scooping members having triangular recesses which cause the mixture to move towards the outlet, whence it is removed by an ejector to a rotary horizontal cylindrical ore tank connected with a condenser.—T. H. B.

XII.—FATS; OILS; WAXES.

Emulsification; Theory of—based on pharmaceutical practice. H. W. G. Crockett and R. E. Oesper. J. Ind. Eng. Chem., 1917, 9, 967–969.

THE conclusions drawn in a previous communication (this J., 1917, 394) have been confirmed by the determination of the critical proportions required to form emulsions with other systems. The materials used as internal phases were carbon tetrachloride, chloroform, benzene, oil of turpentine, almond oil, and mineral oil of sp.gr. 0.853; whilst the emulsifying agents were powdered gum

arabic, tragacanth, extract of Irish moss, and soft soap. It was found that the size and shape of the vessel in which the emulsion is made has a distinct influence upon the critical point. In the case of tragacanth emulsions better results are obtained by adding the right proportion of water to the previously mixed internal phase and emulsifier, than by adding the water in instalments and shaking after each addition. No emulsion is formed when the critical amount of tragacanth is mixed with water, and the mucilage then shaken with the internal phase, but the critical points are not affected by allowing the dried internal phase to stand in contact with the emulsifier before adding the water. Emulsions made with Irish moss extract are not affected by the addition of small amounts of alcohol, but are immediately broken up by the addition of a trace of soap, either before the addition of water, or after emulsification. Larger quantities of soap, however, promote emulsification by means of Irish moss. The addition of glycerin prevents this action of a trace of soap, and re-emulsifies emulsions which have thus been broken, but glycerin does not directly aid Irish moss as an emulsifier. Gum arabic emulsions are not broken up by a trace of soap; on the contrary the emulsification is promoted, but the soap cannot replace part of the critical amount of gum arabic. Viscous oils show less distinct critical points than those of less viscosity. Tragacanth is an unsuitable agent for emulsifying mixtures of fixed oils with water, since it produces a thick mass.—C. A. M.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Shellac derivatives; Imbibition exhibited by some—A. P. Laurie and C. Ranken. Roy. Soc. Proc., 1917, A, 94, 53–59.

THE solid which separates on cooling a solution of shellac in boiling sodium carbonate, when immersed in cold water, expands rapidly and ultimately disintegrates to a flocculent precipitate. If immersed in water and allowed to expand to a point short of disintegration, subsequent immersion in strong sodium carbonate solution causes contraction; on being replaced in water expansion again occurs, and so alternate expansion and contraction can be obtained. Measurements were made of the expansion in water and in solutions of salts (sodium chloride and sulphate, ammonium acetate, and potassium chloride) of different concentrations, of this compound and of that obtained by dissolving shellac in borax solution and solidifying

by cooling, and it was found that expansion is inversely proportional to the concentration of the solution. The soluble portion of the compound fully expanded in water is precipitated by strong but not by dilute salt solutions, thus differing from colloids. The differences between the behaviour of the compound and that of substances such as gelatin and gum tragacanth are largely explained by this insolubility of the soluble portion in strong salt solutions. On allowing gum tragacanth to expand in a medium containing a constituent in which it is insoluble, *e.g.*, the alcohol in a medium of alcohol and water, similar behaviour was observed, the expansion being inversely proportional to the concentration of the alcohol. Since the shellac compound is permeable to salt molecules, the mechanism of the expansion seems to be accounted for by the passage of the salt molecule through the diaphragm, the soluble nucleus dissolving in the presence of the salt solution, and the amount that can dissolve controlling the consequent osmotic pressure.—A. DE W.

Varnish material: Process of making—C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co., and Indestructible Paint Co., Ltd., London. U.S. Pat. 1,242,161, Oct. 9, 1917. Date of appl., Mar. 29, 1915.

RESIN esters are produced by agitating a mixture of resin or its anhydride and unchanged or cracked Congo copal gum with glycerin in the presence of aluminium at a temperature above 300° C. at ordinary pressures. The esterified product may then be re-cracked.—A. DE W.

Hardening resins and products thereof: Process for—F. S. Low, Buffalo, N.Y. U.S. Pat. 1,243,312, Oct. 16, 1917. Date of appl., Jan. 31, 1916.

SOFT natural resins (*e.g.*, rosin) are hardened and rendered more resistant to air and light and less fusible, whilst retaining substantially their general properties, by heating under pressure with formaldehyde in the presence of water vapour.—A. DE W.

Phenolic condensation compounds: Process of producing—[Phenolic] condensation product and method of preparing same. L. V. Redman, Evanston, and A. J. Weith and F. P. Brock, Assignors to Redmanol Chemical Products Co., Chicago, Ill. U.S. Pat. (A) 1,242,592 and (B) 1,242,593, Oct. 9, 1917. Date of appl., June 19, 1916.

(A) A FUSIBLE "potentially reactive moulding product" is obtained by mixing a phenolic compound with an active methylene-amine compound in such proportion that the phenolic compound is in considerable excess of one phenolic group to each methylene group, eliminating ammonia by heating, blowing out of the mass a considerable percentage of the free phenolic compound, and incorporating a small proportion of creosote oil and sufficient methylene-amine compound to be capable of converting the product to the infusible state. The product is then blended and fused without effecting conversion to the final infusible state. (B) A phenolic condensation product is produced by heating a phenolic compound with an active methylene compound in the proportions of an excess of considerably more than one phenolic group to each active methylene group, and then incorporating into the fusible mass a filler and a cyclic compound having no readily reactive group, *e.g.*, creosote oil.—A. DE W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber: Depolymerisation and oxidation of raw—A. van Rossem, Communications of the Netherlands Govt. Inst. for Advising the Rubber Trade and Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies. 1917, Part IV., 111—121.

WHEN rubber is worked on normally heated rolls the most marked decrease in viscosity occurs in the first ten minutes, but on prolonged treatment, *e.g.*, for 89 minutes, it is found that first latex crepe rubbers of different initial viscosity appear to tend towards identical final viscosity, which on account of its diminution is best estimated in 10% solution. Experiments with raw Congo rubber indicate that washing with cold water and subsequent drying effect a considerable decrease in the viscosity; the method of drying is of influence, the use of a vacuum desiccator yielding the most trustworthy results. Experiments with hard fine Para rubber showed that although working on the rolls beyond the normal period of ten minutes causes a decided further decrease in viscosity, the proportion of constituents soluble in acetone remains unaltered throughout, the only marked change in composition being a reduction in the proportion of moisture present. Rubber undergoes "depolymerisation" also when heated in solution (see Van Rossem, this J., 1917, 1104) or in the solid state, and this probably accounts for the fact that on drying rubber *in vacuo* at 50° C., a greater reduction in viscosity is observed than when the drying is effected at the ordinary temperature. It was also found that subsequent storage for 13 days did not restore the original viscosity but actually caused a slight further decrease. These tests were made with Congo rubber. If rubber (Hevea crepe in the experiments cited) is heated at 130° or 140° C. in an atmosphere of carbon dioxide for several hours, the viscosity undergoes very marked reduction, but unlike the original rubber, the heated rubber is not completely soluble in benzene and the insoluble fraction probably contains some of the more viscous constituents; heating in air at 80° C. also causes a diminution in viscosity but the decrease is less marked, probably because the treated rubber obtained under these conditions is entirely soluble in benzene. In any case this effect of heat on the mechanical properties of rubber deserves serious consideration in connection with the ordinary process of smoking freshly coagulated rubber. The depolymerisation of rubber can also be accelerated by exposing solutions to ordinary or ultraviolet light, whether in the presence of air or of an inert gas; chemical influences also can be active in this direction, the viscosity of rubber solutions being notably reduced on treatment with potassium permanganate (Harries, this J., 1901, 830), with small quantities of an acid, with bromine, or, at higher temperatures, with oxygen, the effect apparently being catalytic. When a Hevea rubber which has been worked on the rolls is kept for 20 days there is a slight increase in the viscosity, but after such storage further treatment on the rolls has a very unfavourable influence on the viscosity; much higher viscosity values were obtained with a rubber-sulphur mixing which immediately after the first treatment on the rolls was passed a further ten times between the rolls, than with a part of the same mixing which was given a similar additional treatment but on the following day: the frequent practice of storing masticated rubber for a period and then re-masticating therefore appears to be detrimental. With respect to the oxidation of rubber, the view is held that this is a secondary process which can only occur

after previous depolymerisation to a definite critical viscosity, and the oxidation process is believed to involve the intermediate formation of peroxide compounds. The injurious action of copper compounds on rubber is confirmed and is regarded as due to a depolymerising effect rather than to a process of oxidation.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin; Effect of hard water on—E. Schell, La Halle aux Cuirs, Aug. 12, 1917. J. Amer. Leather Chem. Assoc., 1917, 12, 569—570.

ANALYSES of chestnut extract made with boiled and filtered Paris water containing 0.004 grm. of calcium carbonate per 100 c.c., showed 2—2½% less tannin than analyses made with distilled water. The discrepancy was removed if the water was first boiled, filtered, and acidified. A factory using 500 tons of extract a month would lose

20,000—25,000 lb. of tannin per month if using water similar to the above. The loss of tannin was proved by direct experiment to be caused by calcium and magnesium carbonates.—F. C. T.

Tannins; Notes on the analysis of—L. E. Levi and A. C. Orthmann. J. Amer. Leather Chem. Assoc., 1917, 12, 515—518.

THE authors define tannin as "tannic acid and its homologues, either separate or in combination, that will combine with hide fibre, either physically or chemically, to render the same imputrescible." The hide powder method of analysis does not determine this factor, but each and every substance, including much colouring matter, that combines with, or is mechanically absorbed by, hide. This difficulty the authors claim to overcome in a measure by analysis with their "reagent No. 33," which leaves colouring matters in the non-tannin solution. A factor is necessary, however, for the various materials when analysed by the special reagent. The reagent contains the compound $\text{Cr}_2\text{SO}_4(\text{C}_2\text{H}_3\text{O}_2)_2\text{CrO}_4$; its preparation is described in this J., 1911, 1269.—F. C. T.

Sole leathers; Wear resistance of—III. L. Balderston. J. Amer. Leather Chem. Assoc., 1917, 12, 523—529. (See also this J., 1916, 935, 1072.)

A MACHINE is described and illustrated, which is designed to imitate the action of the foot in walking. No standard method of testing has yet been arrived at, as difficulties have arisen in preparing a suitable wearing surface corresponding to pavements. One series of tests with a concrete slab showed that betting leather will outwear some sole leathers.—F. C. T.

Gelatin solutions; Sol and gel condition of—L. Arisz. Kolloidchem. Beilhefte, 1915, 7, 1—90. J. Soc. Leather Trades' Chem., 1917, 45—51.

EXPERIMENTS were carried out with solutions of purified gelatin in glycerin containing 32% of water. It was found that above 65° C., solutions of gelatin show permanent loss of viscosity due to partial hydrolysis, and this effect becomes more marked with increasing temperature. When temperature changes occur below 65° C. there are two kinds of viscosity change, both reversible, occurring simultaneously. One is the ordinary change due to temperature alone, and the other a change dependent on time, but slow, and always tending to a definite "inner" equilibrium viscosity which is fixed for any temperature with a given solution. If temperature change is infinitely slow, the "inner" equilibrium-viscosity curve is followed; if the change is rapid, viscosity varies with temperature alone, though its absolute value depends on how much slow viscosity change has taken place before the rapid temperature change commenced. The slow change is probably due to the formation or dissolution of molecular complexes. Thus a 10% jelly suddenly raised to a temperature slightly above the gelatinising point does not at once melt, and continues to lose viscosity for many hours. On the other hand, if it is rapidly cooled and gelatinised at 35° C., and at once heated to the gelatinising temperature (44° C.), it first melts, and only gradually resumes the gelatinised condition. Gelatinisation is best regarded as a point of rapid increase of viscosity, and a viscosity can be fixed which is the limit of gelatinisation for all temperatures, and below which all solutions are liquid. At lower temperatures the viscosity is diminished by mechanical agitation, which breaks up the complexes. This effect is imperceptible above 65° C. The Tyndall effect is affected by time, temperature change,

and previous history, in the same directions as viscosity. There is no kink in curves of viscosity or Tyndall effect at the gelatinisation or melting point, though as gelatinisation is gradual, a change in the curve may possibly have been overlooked. The properties of jellies seem more or less common to the liquid solutions—for instance, double refraction under stresses. Gelatin-glycerin solutions are more viscous than aqueous gelatin solutions of the same concentrations and have higher setting points, though in very dilute solutions the reverse is the case; a $\frac{1}{2}\%$ glycerin solution of gelatin will never set.—F. C. T.

PATENT.

Tanning. A. Turnbull and T. B. Carmichael. Liverpool. Eng. Pat. 110,470, Feb. 24, 1917. (Appl. No. 2717 of 1917.)

THOROUGH absorption of tanning materials by hides from relatively strong solutions of the tanning agents is attained by mixing starch with the solution of tanning material, heating the mixture until a jelly is formed, and steeping the prepared hide in the cooled jelly. For instance, 500 lb. of chrome alum is dissolved in 125 galls. of hot water, 64 lb. of soda ash previously dissolved in 250 galls. of hot water is added slowly, the liquid is heated above 180°F. (82.5°C.) and about 250 lb. of powdered starch stirred in. Basic chrome alum tannage or basic aluminium sulphate tannage may be applied alone, or in combination with vegetable tannage, by adding to the above bath 750 lb. of gambier before the starch, or a plain vegetable extract, e.g., 500 galls. of a strength of 125° barkometer, may be used for gelatinising 250 lb. of starch.—J. F. B.

XVI.—SOILS; FERTILISERS.

PATENT.

Fertilisers for seeds and plants. N. A. Barbieri. Rome. Eng. Pat. 110,338, Sep. 29, 1917. (Appl. No. 14,070 of 1917.) Under Int. Conv., Aug. 20, 1917.

THE fertiliser consists of 30–35 parts of potassium sulphate, 20–25 parts of acid potassium phosphate, 20–35 parts of calcium phosphate, 20–25 parts of magnesium phosphate, and 20–25 parts of calcium sulphate, with 5% of silica, 5% of calcium carbonate, and 0.02% of manganese sulphate. The seeds to be sown are mixed with suitable proportions of the fertiliser.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

PATENT.

XVIII.—FERMENTATION INDUSTRIES.

Vinegar; Notes on the manufacture of —. C. A. Mitchell. J. Inst. Brewing, 1917, 23, 357–372.

IN vinegar manufacture, in which the aim is to obtain as high a yield of alcohol as possible, a malt of fairly high diastatic capacity (say about 80) is used and mashing is effected at a much lower temperature than in breweries. In some vinegar works the first mash is made at about 140°F. (60°C.), and the second mash at about 140° to 150°F. (60° – 65.5°C.), and the goods are then sparged with water at 150° to 160°F. (65.5° – 71°C.) Better results may be obtained by making the

first mash at about 120°F. (49°C.) and, after starting the rakes, gradually raising the temperature to about 150°F. (65.5°C.). Naked steam may be admitted for this purpose from pipes below the false bottom of the tun without having any injurious effect upon the mash. In cooling the wort it is permissible to leave it at a much higher temperature than is possible in a brewery. In fact when using certain yeasts it is advisable to have the wort at a temperature of 72° to 74°F. (22° – 23°C.) so as to prevent too vigorous growth and to obtain a better attenuation. If these conditions are complied with there should be no difficulty in attenuating a wort of sp. gr. 1.055 to about 1.001. It is an advantage to store the gyle for several months before acetification as it gradually becomes acid and thus saves time in the acetifiers. New wash should not be used in the acetifying apparatus, since the suspended yeast cells interfere with the action of the acetic bacteria, and form a slimy deposit on the acetifying medium. Alcoholic fermentation may even start again when new wash is pumped over in an acetifier at a temperature which is too low to kill the yeast cells. Very many species of acetic bacteria have been described, but there is reason to believe that some of these are not distinct species. *Bacterium xylinum* isolated by Brown (J. Chem. Soc., 1886, 39, 432) from sour malt wort, is the species of most common occurrence in this country. The formation of its zoogloal form (the tough leathery pellicle known as "vinegar plant" or "mother-of-vinegar,") is promoted by the presence of only a limited supply of air, and its excessive formation is not an uncommon occurrence in acetifiers to which air is not being supplied in sufficient quantity. The acetifying medium then becomes rapidly choked with "mother," and the acetifier must be stopped and cleaned. Acetic bacteria are affected by sunlight, and experiments made by Giunti and by Tolomei have shown that the violet rays of light inhibit acetic fermentation. Hence there was scientific justification for the precautions taken by the old vinegar makers to exclude daylight from the acetifying rooms, although the results obtained by Tolomei in a series of acetic fermentations beneath glass of different colours show that the use of windows of red or orange glass would have been quite as effectual a safeguard as working in the dark. Now that large acetifiers have replaced small barrels it is quite unnecessary to keep the acetifying rooms, or "stoves" as they are technically termed, in darkness, for these large vats are closed, and the effect of the small amount of light which can find its way through the aeration holes is negligible. So far few attempts have been made to use pure cultures of acetic bacteria, although it has been shown by Villon that the use of specific cultures affected not only the speed of acetification, but also the flavour and aroma of the vinegar. The most important factor in acetification is to supply the correct proportion of air to the bacteria, and various porous media, such as shavings, twigs, or basket work, upon which the bacteria can develop, are used for charging the acetifiers. It is essential that the total area of the air holes below the false bottom should approximately equal the area of the regulated ventilator or of the holes through which the spent air leaves the top of the vat. To prevent the irregular aeration due to the formation of channels in beds of shavings and the like, the so-called plate acetifiers have been introduced into some vinegar works. Bersch's acetifier, for instance, is rectangular in form, and is packed above the false bottom with frames fitted with slats of wood, leaving spaces of about $\frac{1}{2}$ in. between the slats. Theoretically, this offers a very large surface for aeration, and it is claimed by the inventor that it will give a theoretical yield of

vinegar. This is not borne out by the author's experiments with this acetifier under English conditions of working. For example, the best result obtained was a yield of 0.96% of acetic acid in 24 hours at the cost of 0.97% of alcohol by weight. Moreover, this acetifier loses its efficiency in a short time owing to the frames becoming choked up with mother-of-vinegar, which is very difficult to remove when the frames are cleaned. The optimum temperature for acetification varies with the species of bacteria. On the Continent wine and spirit vinegars are acetified at about 86° to 95° F. (30°—35° C.), and above this higher limit acetification proceeds very slowly, and the bacteria are weakened or destroyed. In this country acetic bacteria produce the best results

in the milk has the same effect as the addition of water upon the constant, but since formaldehyde in sufficient quantity to preserve the milk does not affect the results, it is possible to keep samples for 12 days before examining them by this method. On the other hand, the cryoscopic method is more accurate for the detection of a small amount of added water, and is therefore preferable for the examination of fresh milk.—C. A. M.

† Extractive matter direct.

at 105° to 110° F. (40.5°—13° C.). It is possible that this may be partly due to acclimatisation, seeing that the early large acetifiers were fitted with tin steam coils for maintaining a high temperature. At the present day, only a slight initial heating of the gyle is required, and the temperature then rises spontaneously to well over 100° F. (38° C.), through the heat of oxidation. High temperatures are advantageous in preventing the development of vinegar eels within the acetifiers, but, on the other hand, increase the loss of acetic acid by volatilisation. After acetification the crude vinegar, which contains about 6% of acetic acid, is stored for a month or two to develop its aroma and to facilitate the subsequent filtration, and is then diluted to the strength required by the trade. The different "trade numbers" (Nos. 16, 18, 20, 22, and 24) used to designate the various strengths of vinegar are said to denote the number of grams of sodium carbonate neutralised by 1 oz. of the vinegar, but the evidence points rather to their indicating the price in pence at which a gallon of vinegar was sold.—C. A. M.

XIXa.—FOODS.

Milk; Detection of added water in — by means of a simplified molecular concentration constant. L. W. Ferris. *J. Ind. Eng. Chem.*, 1917, 9, 957—959.

EXAMINATION of 31 samples of milk showed that the molecular concentration constant of Mathien and Ferré (this J., 1914, 214) varied from 71.1 to 82.6, and that the method was capable of detecting 8% of added water. The development of acidity

A study was made of the action of enzymes and also of yeast on cacao, and fermented samples compared with those which had not undergone fermentation. Changes produced by fermentation are not easily demonstrated by chemical analysis, but have a considerable effect on the organoleptic properties of the cacao. Sack's statement (*Bull. Dept. Agric. Surinam*, 10) that during fermentation a glucoside is hydrolysed with formation of theobromine and cacao-red, could not be confirmed. The sucrose content diminishes, frequently to zero; the glucose (including maltose) first decreases, and then increases slightly as a result of diastatic hydrolysis of the starch. The starch content is not notably altered, but it is probable that the so-called "break" of fermented cacao is a change in the character of the starch. The most evident change shown by analysis is a decrease in astringent matter, and this accounts in part for the improvement in the flavour of the fermented cacao. The free acid of the cacao butter increases with the duration of fermentation, but only slowly, as Philippine cacao does not contain a lipase. The best results in fermentation are obtained by the combined action of the enzymes of cacao and of yeasts. Cacao fermented by the action of yeasts or taka-diastase on beans which had been heated in water to destroy the enzymes present, was inferior to that fermented by the agency of the cacao enzymes alone, i.e., in presence of toluene, chloroform, or alcohol. In addition to the enzymes mentioned previously (this J., 1916, 136), an emulsin-like enzyme has been detected which is somewhat more active in the unfermented seeds than in the fermented product.—L. A. C.

Coal tar colours [in foodstuffs]: Modification of the Price method of separating — to include Tartrazine. E. H. Ingersoll. *J. Ind. Eng. Chem.*, 1917, 9, 955—957.

By Food Inspection Decision, U.S.A., No. 164, Tartrazine may be added to the seven coal tar colours allowed, under certain restrictions, to be

used in food. To include this colour the following modification of Price's scheme (U.S.A. Dept. Agric., B.A.I. Circular 180) has been devised:—From 0.1 to 0.2 gm. of the sample of colour is rubbed in a mortar with 25 c.c. of a saturated solution of ammonium sulphate, and the liquid filtered. If the filtrate is red the residue is washed with successive portions of 10 to 15 c.c. of the ammonium sulphate solution until the washings are no longer red. The filtrate and washings, which will contain the greater part of the Amaranth, with some Naphthol Yellow S, and some Tartrazine, are shaken with ethyl acetate to remove the Naphthol Yellow S, and then with acetone to extract the Amaranth and Tartrazine. The acetone extract is diluted with an equal volume of water, the acetone evaporated, and the aqueous solution saturated with sodium chloride, and shaken with 10 c.c. of alumina cream. The precipitate is separated, washed free from Tartrazine, and the Amaranth recovered by suspending the alumina precipitate in saturated ammonium sulphate solution and shaking with acetone. The portion of the original sample insoluble in the ammonium sulphate solution is dissolved in water, the solution acidified with acetic acid, and shaken with successive portions of ether to remove Erythrosine, the ethereal extract washed, and the Erythrosine extracted from the ether with dilute ammonia solution. The ether is evaporated from the residual acetic acid solution, which is then saturated, while hot, with sodium chloride, an excess being finally added, and filtered. The precipitate is washed with saturated sodium chloride solution, and, if necessary, the "salting out" and washing is repeated. The combined filtrate and washings may contain Light Green S.F. Yellowish, Naphthol Yellow S, Tartrazine, traces of Orange I, and possibly Amaranth, not completely removed by the first extraction with ammonium sulphate. Naphthol Yellow S is separated by extracting the liquid with acetone, and the extract is washed several times with saturated sodium chloride solution to remove traces of Tartrazine and Light Green S.F. Yellowish, and then diluted with an equal volume of water, and heated on the water-bath to remove the acetone. The aqueous solution is acidified and shaken with amyl alcohol to remove traces of Orange I, and the amyl alcohol evaporated from the aqueous layer, which will then contain the Naphthol Yellow S. To separate Light Green S.F. Yellowish from Tartrazine, the acetone is evaporated from the aqueous salt solution, which is then treated, while warm, with 0.5 gm. of fuller's earth for each 10 c.c. of solution. After thorough mixing and settling, the liquid is filtered from the precipitated Light Green S.F. Yellowish, which may then be dissolved in hot acetic acid and identified. In the presence of Tartrazine the filtrate will be yellow and not decolorised by hydrochloric acid, whereas any traces of Naphthol Yellow S not previously separated would be decolorised by the acid. The precipitate containing Orange I, Ponceau 3R, and Indigo Disulpho Acid, and excess of sodium chloride is dissolved in water and extracted with three successive portions of ethyl acetate, which will remove the Orange I. The united extracts are washed with saturated sodium chloride solution, and the Orange I may then be extracted with water. The aqueous residue from the ethyl acetate extraction is heated on the water-bath until free from ethyl acetate, then treated with 10 grms. of granulated calcium chloride, and, after 15 mins., with 15 c.c. of a freshly prepared stannous chloride solution containing the equivalent of 3% of metallic tin and 12% of hydrochloric acid (sp. gr. 1.19). The mixture is allowed to stand until the solution shows no blue colour, and the precipitated Ponceau 3R is filtered off, washed with 25% calcium chloride solution, and dissolved in

dilute ammonia solution. The filtrate, which should be practically colourless, is treated with 3% hydrogen peroxide solution, which, in the presence of Indigo Disulpho Acid, will produce a deep blue coloration.—C. A. M.

Fibrin: Comparative analyses of— from different animals. R. A. Gortner and A. J. Wuerz. J. Amer. Chem. Soc., 1917, 39, 2239—2242.

FIBRIN was prepared from the blood of cattle, sheep, and swine, and the hydrolytic products from the various samples were examined by the Van Slyke method. The results were as concordant as could be expected from the method employed and are regarded as evidence that fibrin from the named sources can be used interchangeably for experimental purposes.—D. F. T.

PATENTS.

Butter, margarine and the like: Preparation of a substitute for— J. Schortinghuis, Zoeterwoude, Holland. Eng. Pat. 110,293, Mar. 26, 1917. (Appl. No. 4372 of 1917.)

MILK powder is made into an emulsion with water, salt being added if desired, and the product is heated to 40—60°C. and intimately mixed with olive oil or other vegetable oil. Natural butter and vegetable fat are then added in order to obtain the proper consistency and increase the amount of volatile fatty acids, and the whole is forced through a sieve to form a homogeneous mass. This is melted at 40—60°C., cooled, mixed, allowed to stand for 24 hours, and then turned over.—J. H. J.

Food and process of preparing the same. M. Quinane, Bayonne, N.J., U.S.A. Eng. Pat. 110,401, Oct. 19, 1916. (Appl. No. 14,873 of 1916.)

THE food is prepared by boiling separately rice and wheat bran, then mixing, and introducing as hot sprays, first a suspension of precipitated calcium phosphate in water, and then olive oil. Sugar may be added if desired. The finished food contains 40% of rice, 32% of bran, 3% of calcium phosphate, 7% of olive oil, and 18% of water or sugar solution.—J. H. J.

XIXb.—WATER PURIFICATION; SANITATION.

Antiseptics: Regular and irregular— C. Richet and H. Cardot. Comptes rend., 1917, 165, 491—496. (See this J., 1917, 610.)

IN the previous note a definition of regular and irregular antiseptics has been given, the criterion being the mean relative variation in the acidity produced in a given fermentation process under the influence of the antiseptic. In the present note, this factor has been calculated, from the results of about 10,000 experiments made in 1909 on lactic fermentation. Taking the relative mean variation for the blank as 100, the value found varied from 83 for sodium fluoride to 870 for silver nitrate. The antiseptics fell into four classes. 1. Extremely regular—sodium fluoride (the only one which increased the regularity of the fermentation process). 2. Fairly regular—creosote, lead nitrate. 3. Irregular—phenol, copper sulphate. 4. Very irregular—salts of zinc, silver, mercury. Thus with salts of mercury, at the limiting antiseptic concentration, it is uncertain whether the fermentation will cease altogether or will continue intensively.—H. J. H.

PATENTS.

Sewage and other foul liquids; Apparatus for aerating—R. Ames, Brighton. Eng. Pat. 110,197, Oct. 13, 1916. (Appl. No. 14,547 of 1916.) Addition to Eng. Pat. 104,361, Feb. 25, 1916 (this J., 1917, 519).

THE original apparatus is improved by providing above the tank a rotary chamber, to which the incoming sewage is supplied. From this chamber the sewage flows into troughs, fixed to the chamber on either side, from which depend open-topped vertical pipes with bell-mouth bottoms reaching to within a few inches of the bottom of the tank. The compressed air supply comes from an air chamber on the top of the sewage chamber, the air being conveyed by pipes which pass down the inside of the vertical sewage pipes and end in atomisers situated in the bell-mouths of the sewage pipes.—J. H. J.

Insecticide, sheep-dip, and the like. G. J. Lemmens, Wateringbury, and P. J. Fryer, Tunbridge. U.S. Pat. 1,242,954, Oct. 16, 1917. Date of appl., Jan. 16, 1917.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Arsenic compounds of the anthraquinone group. L. Benda. J. pr. Chem., 1917, [ii.], 95, 74—106. J. Chem. Soc., 1917, 112, i., 599—601.

α -AMINOANTHRAQUINONE, by diazotisation in concentrated sulphuric acid, was converted into the corresponding diazo-compound, which on treatment with a solution of sodium arsenite in the presence of sodium carbonate, gave rise to colourless anthraquinone-1-arsinic acid,

colourless needles. This substance is reduced by sodium hydrosulphite in alkaline aqueous solution at 50° C. with formation of 1.1'-arsenoanthranol,

a deep brownish-red substance, which gives yellow solutions in alcohol and ether, but a blood-red solution in aqueous sodium hydroxide; when exposed to the atmosphere this alkaline solution undergoes rapid oxidation with re-formation of the arsenic acid, but in the presence of sodium carbonate, atmospheric oxidation of the arseno-anthranol proceeds only to yellow anthraquinone-1-arsenoxide,

for the further oxidation of which to anthraquinonearsinic acid hydrogen peroxide is necessary. Anthraquinone-1-arsinic acid, when heated strongly, undergoes decomposition with formation of erythrohydroxyanthraquinone, arsenious oxide, and water; on reduction with sodium

amalgam in alkaline solution, it undergoes fission into anthraquinone and arsenious acid, the ease of this change probably accounting for the high toxicity of the arsenic acids of the anthraquinone group.

Anthraquinone-2-arsinic acid, prepared by a similar process to that adopted for its 1-isomeride, forms yellow needles, which remain unfused at 270° C.; like the 1-compound, it gives precipitates with calcium chloride and with magnesia mixture in ammoniacal solution at the ordinary temperature. It is relatively resistant to the action of sodium amalgam and aqueous alkali, this behaviour being in accord with the fact that it is much less poisonous than the isomeric 1-arsinic acid.

4-Aminoanthraquinone-1-arsinic acid, $\text{C}_{14}\text{H}_{10}\text{O}_5\text{NAs}$ (sodium salt, red needles with $4\text{H}_2\text{O}$), was obtained as a red, crystalline powder, m.pt. indistinct at 278° C. (decomp.), by the interaction of an alkaline solution of sodium arsenite with the product formed on diazotising 1.4-diaminoanthraquinone in dilute sulphuric acid. The product of diazotisation in concentrated sulphuric acid, using an excess of nitrosylsulphuric acid, reacted with sodium arsenite, forming 4-hydroxyanthraquinone-1-arsinic acid, $\text{C}_{14}\text{H}_8\text{O}_5\text{As}$, yellow needles, decomp. above 200° C. (sodium salt, brownish-yellow needles); this yielded a brownish-red precipitate with magnesia mixture at the ordinary temperature, and in solution in sulphuric acid could be nitrated to 3-nitro-4-hydroxyanthraquinone-1-arsinic acid, $\text{C}_{14}\text{H}_7\text{O}_5\text{NAs}$, yellow needles, decomp. near 230° C. Reduction of 3-nitro-4-hydroxyanthraquinone-1-arsinic acid with a restricted quantity of ferrous hydroxide yielded 3-amino-4-hydroxyanthraquinone-1-arsinic acid, $\text{C}_{14}\text{H}_{10}\text{O}_5\text{NAs}$, violet, silky needles, m.pt. near 265° C. The product yields a crystalline diazo-compound (needles), which couples with R-salt and with resorcinol, producing violet- and blue-coloured solutions respectively; it is also reduced by sodium hydrosulphite to an orange-coloured vat, which imparts a violet stain to filter-paper. 1.5-Diaminoanthrarufin was converted by way of its chocolate-brown, crystalline tetrazo-compound into 4.8-dihydroxyanthraquinone-1.5-diarsinic acid (anthrarufindiarsinic acid), $\text{C}_{14}\text{H}_{10}\text{O}_{10}\text{As}_2$, a yellow, microcrystalline powder, decomp. above 270° C. On nitration in sulphuric acid at 80° C. this arsenic acid yielded 3.7-dinitro-4.8-dihydroxyanthraquinone-1.5-diarsinic acid, $\text{C}_{14}\text{H}_8\text{O}_{10}\text{N}_2\text{As}_2$, a greenish-yellow, microcrystalline powder. By treatment in alkaline aqueous solution with sodium amalgam, the dinitro-diarsinic acid was reduced to 3.7-diamino-4.8-dihydroxyanthraquinone-1.5-diarsinic acid, $\text{C}_{14}\text{H}_{12}\text{O}_{10}\text{N}_2\text{As}_2$, a dark violet powder with metallic reflex.

Citrus fruits; Method for the determination of the volatile oil content of—C. P. Wilson and C. O. Young. J. Ind. Eng. Chem., 1917, 9, 959—960.

THE whole fruit is cut up and thoroughly mixed, and 200 grms. is mixed with 700 c.c. of water, and rapidly distilled in a current of steam. The distillate is collected in a special oil flask holding about 200 c.c., and having a neck containing about 2 c.c. and graduated in 0.1 c.c. divisions. After about 200 c.c. has been collected, hot water is added to bring the oil up into the neck of the flask, which is then centrifuged, and the volume of oil read. The volume multiplied by 0.849, the average sp.gr. of Californian lemon oils, and by 0.996, the factor for determinations made at 25°/25° C. in air, gives the weight of oil. Determinations of oil in the peel gave lower results than those obtained with the entire fruit.—C. A. M.

Theory of emulsification based on pharmaceutical practice. Crockett and Oesper. See XII.

PATENTS.

[Blasting] explosives. Kynoch Arklow, Ltd., and L. H. Pirmez, Arklow, Ireland. Eng. Pat. 110,237, Nov. 27, 1916. (Appl. No. 16,989 of 1916.)

BLASTING explosives suitable for use in places where it is desired to avoid or minimise the risk of ignition of inflammable gases, e.g., in coal mines, are prepared by adding fluorides or mixtures of fluorides, e.g., fluorspar or cryolite, to the explosives in proportion varying with their heat of combustion. To blasting powders giving a temperature of less than 2000° C., it is sufficient to add up to 20% of fluorides. For blasting gelatins, giving temperatures up to 3000° C., up to 35% of fluorides may be added. Examples: (A) Nitroglycerin, 11%; ammonium nitrate, 65%; wood meal, 5%; calcium fluoride, 19%. (B) Nitroglycerin, 50%; nitrocotton, 3%; potassium nitrate, 17%; calcium fluoride, 30%. The addition of fluorides reduces the temperature of explosion, with only a slight decrease in the rate of detonation, and renders the explosive less hygroscopic.—F. Sp.

Iron; Calorised—— as an element for thermo-couples. O. L. Kowalke. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 6 pages.

As tested in combination with constantan in thermo-couples, at temperatures up to 1000° C.,

calorised iron (iron having a surface coating of rich aluminium alloy) was found to have the same electro motive force and constancy as uncalorised iron, but a much longer life. A heavy wire, lightly calorised, is the most suitable for thermo-couples.—W. E. F. P.

Gas volumeter; A universal——. H. G. Deming. J. Amer. Chem. Soc., 1917, 39, 2145–2151.

A MODIFICATION of Lange's universal gas volumeter is described in which a scale of mgrms. is substituted for the scale of c.c. usually engraved on the correction tube, and the volume of gas collected in the measuring tube gives the percentage of any desired constituent directly, if measured when the mercury in the correction tube has been adjusted to a mark corresponding to the weight of substance taken for analysis.—F. PATENT

Firedamp in mines; Apparatus for detecting——. T. J. Thomas, Porth, Glamorgan. Eng. Pat. 110,439, Nov. 29, 1916. (Appl. No. 17,158 of 1916.) Addition to Eng. Pat. 15,694, Oct. 26, 1915 (this J., 1916, 1273).

THE apparatus described in the principal patent is modified by the introduction of a resistance in parallel with the catalytic body, so that when the latter fuses in the presence of firedamp, the current passes through the resistance to the lamp, thereby giving a light of reduced intensity.—F. Sp.

Official Notices.

PROHIBITED EXPORTS.

An Order-of-Council, dated 18th December, 1917, makes the following alterations in the list of export prohibitions* :—

The following headings are deleted :—(A) Coke, petroleum; (B) Coke, except petroleum coke; (A) Firebricks and fireclay; (B) Fuel, manufactured; (C) Zinc-barium pigments made from zinc salts and barium sulphate (except zinc oxide); (C) Matches; (B) Terebene, and articles containing terebene; (B) Turpentine (oil and spirit) and articles containing turpentine; (A) Turpentine substitute, not otherwise specifically prohibited, and articles containing such substitute; (B) Varnishes containing shellac, oil, or turpentine, not otherwise prohibited.

The following headings are added :—(A) Coke and manufactured fuel; (A) Fireclay, and articles manufactured of fireclay, including firebricks; (A) Incandescent gas mantle rings; (A) Matches; (A) Terebene, and articles containing terebene; (A) Turpentine (oil and spirit), and articles containing turpentine; (A) Turpentine substitute, and articles containing turpentine substitute.

PURCHASE OF PYRITES MINED IN THE UNITED KINGDOM.

It is officially announced that the Ministry of Munitions is prepared during the period of hostilities to purchase iron pyrites mined in the United Kingdom. The pyrites must contain not less than 37½% of sulphur and not over 1% of arsenic. The price payable will be 35s. per ton of pyrites f.o.r. for quantities of not less than one truck load, but the Minister reserves the right to revise the price after 31st December, 1918, or, if over 5000 tons are delivered from one deposit before that date, the price may be revised in respect of further deliveries from such deposit forthwith. In the first instance samples of all ore tendered will be selected by the Local Agent of the Ministry, and if, upon analysis, the ore proves suitable, payment of 75% of the amount of the purchase price for each consignment will be made on receipt of the railway company's certificate that the pyrites has been put on rail. The balance will be paid within 16 days of the receipt of correct accounts. Producers can obtain detailed particulars on application to the Department of Explosives Supplies, Storey's Gate, Westminster, S.W.1.

DEALINGS IN ACETIC ACID.

With reference to the Order of the Minister of Munitions, dated 1st October, including acetic acid among the war materials to which Defence of the Realm Regulation 30A applies, the Minister has given notice that, as from 18th December, all applications for permits to deal in acetic acid, and other applications and enquiries regarding the

above-mentioned Order, should be addressed to the Director of Propellant Supplies, Explosives Supply Department, 32, Old Queen Street, Westminster, London, S.W.1. The notice cancels the footnote to the Order which directed applications and enquiries to be addressed to the Chemical Section, Trench Warfare Supply Department.

TRADING IN TUNGSTEN ORES, MOLYBDENITE AND METAL, AND PRODUCTS THEREFROM.

The Minister of Munitions has made an Order, dated 30th November, ordering that the "War Material" to which Regulation 30A of the Defence of the Realm Regulations applies shall include the following :—All tungsten-bearing ores and tungsten metal and alloys and salts derived or produced therefrom, and all molybdenite and molybdenum metal and alloys and salts produced or derived therefrom. Under this Order returns are required respecting stocks of the above material, the weekly output and deliveries from mines in the United Kingdom, consignments from outside the United Kingdom, receipts and consumption, output and deliveries of manufactures from such material, receipts from producers, and consumption in manufacture. The returns are to be made on the prescribed forms to the Controller of Non-Ferrous Materials Supply, Ministry of Munitions, 8, Northumberland Avenue, London, W.C. 2. Applications for permits under this Order should be made to the Controller as above.

All ore to which the above Order applies imported into the United Kingdom will be taken possession of by the Minister of Munitions and at a price which will be notified from time to time by the Minister of Munitions. Ores to which the above Order applies imported into the United Kingdom under a contract made before 1st September, 1915, will be released by the Minister of Munitions for delivery in pursuance of such contract, but only for delivery to a consumer for manufacture in his own works and in no case for resale. All other ores must be dealt with as directed by the Controller. Ores ready for delivery will be sampled and assayed by analysts appointed or approved by the Minister of Munitions. The Minister of Munitions will from time to time fix the maximum prices at which ores and products to which the above order applies may be bought and/or sold. Permits to sell for export will be granted only to manufacturers or producers for sale to a consumer at a price approved by the Controller.

Application for permits to export to Allied Countries must be made through the Commission Internationale de Ravitaillement. No application for a permit to purchase will be considered unless the applicant states in detail :—(A) The class and quantity of material it is proposed to purchase; (B) the use to which the material is to be put; (C) the period for which the supply will suffice; and (D) the name of the manufacturer by whom the material is to be supplied.

VEGETABLE PARCHMENT PAPER.

The Army Council have made an Order, under date 3rd December, giving notice that it is their intention to take possession of all stocks of vegetable parchment paper, excepting stocks of less than 10 cwt., that are at present or may hereafter

* The prohibition of exports is as follows :—

Goods marked (A), to all destinations;

Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Sea, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

arrive in the United Kingdom. All persons having in their custody or control any such stocks are required to make a return thereof, with full particulars of quantity, description and cost price to the Director of Army Contracts, Room 35A, Imperial House, Tothill Street, London, S.W. 1, together with all such further and other particulars as to their business as may be required by or on behalf of the Director of Army Contracts.

POTASSIUM COMPOUNDS FOR MEDICINAL PURPOSES.

The Controller of Potash Production has licensed until further notice the purchase by any person of potassium compounds coming within the terms of the Order of 17th October restricting dealings in such compounds, notwithstanding that such purchases may exceed an aggregate of 3 lb. per month, *provided that the compounds so purchased are used solely in B.P. form or in B.P. preparations for purely medicinal purposes.* By this general licence retail druggists, hospitals and similar institutions, medical men and others, are relieved of the onus of applying for individual licences to purchase compounds coming within the conditions indicated in italics above, and wholesale druggists and others may supply such compounds for use as above set out without the necessity of verifying that the purchaser holds an individual licence to purchase or take delivery. It will, however, be necessary for the wholesaler in making his returns to the Controller to state the aggregate amount and value of his sales of compounds for purely medicinal purposes during the period covered by each return. Special forms of return will be provided for this purpose. All sales of compounds, other than those exceeding 3 lb. aggregate per month per person, and the sales for medicinal purposes now licensed, must be conducted strictly under purchasers' licences as prescribed by the Order, and, together with an aggregate statement of sales under 3 lb., and of those for medicinal purposes, must be shown on the returns as at present.

EXPORTS FROM THE UNITED STATES.

The following is taken from a list of articles the conservation of which has been declared to be necessary on account of the limited supply, and the needs of the United States in its successful prosecution of the war (the "Conservation List"). Licences for the export from the United States of the articles included in the list may be granted when they are destined for actual war purposes or when they will directly contribute thereto. Licences may also be granted in certain unusual cases when such exports will contribute directly to the immediate production of important commodities required by the United States, and also in certain other cases when these commodities may be exported in limited quantities without detriment to the country.

Acetone. Alcohol. Aluminium. Ammonia salts. Amorphous phosphorus. Ammonia nitrate. Anhydrous ammonia. Animal fats. Arsenate of lead. Arsenate of soda. Babbit metal and other anti-friction metals. Bichromate of potash. Bismuth salts. Brass, articles of. Bronze, articles of, unless containing less than 10% of copper. Carbolic acid (phenol). Castor oil and castor beans. Caustic potash. Caustic soda. China wood oil. Chrome nickel steel. Chrome steel. Chromium: ore; any metal, ferro-alloy, or chemical extracted therefrom. Cobalt: ore; any metal, ferro-alloy, or chemical extracted therefrom. Copper: ore; any metal, ferro-alloy, or chemical extracted therefrom, unless containing less

than 10% of copper. Cottonseed oil. Crucibles. Cyanide of sodium. Diamonds (industrial). Ferrochrome. Ferrocobalt. Ferromolybdenum. Ferromanganese. Ferronickel. Ferrosilicon. Ferrotungsten. Ferrovanadium. Glycerin. Graphite electrodes. Hydrofluoric acid. Lard. Lard compound. Manganese: ore; any metal, ferro-alloy, or chemical extracted therefrom. Mercury. Mercury salts. Molybdenum. Molybdenite. Naxos emery. Nitrate of soda. Nitric acid. Nickel and nickel alloys. Nickel (more than 5%); ore; any metal, ferro-alloy or chemicals extracted therefrom. Nitric salts. Oil cake. Oil cake meal. Phosphoric acid. Phosphorus. Pig iron. Plumbago (graphite, imported, and articles manufactured therefrom). Potash, and chloride of potash. Potassium salts. Sal ammoniac. Saltpetre. Scrap iron. Scrap steel. Scheelite. Soaps. Sodium phosphate. Sodium sulphite. Solder. Spiegeleisen. Stearine and stearic acid. Sugar. Sulphate of ammonia. Sulphur and sulphuric acid. Superphosphate. Tallow. Tin and any metallic alloy containing tin: chloride of tin; tin ore; tinfoil. Tinplate. Tungsten: ore; any metal, ferro-alloy, or chemical extracted therefrom. Toluol. Type metal. Vanadium. Vegetable oils. Wolframite. Yellow phosphorus.

The War Trade Board has determined that the following derivatives of benzol, phenol, and toluol will require an export licence when shipped to any country of the world. Such of these, however, as are not on the "Conservation List" will proceed to Canada, as heretofore, under the special licence issued through the Customs service: Acetanilide; aniline oil; aniline salts; amidoazobenzol; amidophenol (*p*-amidophenol); benzol; betanaphthol; carbolic acid (phenol); chlorbenzol (monochlorbenzol); cresols; dinitrobenzol (*m*-dinitrobenzol); dinitrochlorbenzol; dinitrophenol; dimethylaniline; diphenylamine; nitroacetanilide (*p*-nitroacetanilide); nitroaniline; nitrobenzol; nitrophenol (*p*-nitrophenol); nitrotoluol (*o*-nitrotoluol, *p*-nitrotoluol); nitroxylols; nitrocresols; nitronaphthalenes; nitrochlorbenzol (*p*-nitrochlorbenzol); nitrosodimethylaniline; naphthalene; *p*-nitraniline; phenol (carbolic acid); tetranitroaniline; tetranitromethylaniline; tetranitroethylaniline; toluol; trinitrotoluol; toluidine (*o*-toluidine, *p*-toluidine); xylydine; xylol.

UNITED STATES: PROHIBITED EXPORTS.

A Proclamation of the President of the United States, dated 28th November, prohibits the importation of the undermentioned articles into the United States, except under licence:—Antimony, antimony ore or any chemical extracted therefrom; asbestos; beans of all kinds; balata; castor seed; castor oil; cotton; chrome, chrome ore, or any ferro-alloy or chemical extracted therefrom; coconut oil; cobalt, cobalt ore or any ferro-alloy or chemical extracted therefrom; copra; diamonds, industrial; ferro-alloys, of all kinds; flax; gutta, joolatong; gutta percha; gutta siak; hemp; hides and skins; jute; iridium; leather; manganese, manganese ore or any ferro-alloy or chemical extracted therefrom; mica; molybdenum, molybdenum ore or any ferro-alloy or chemical extracted therefrom; Naxos emery and Naxos emery ore; nickel, nickel ore, matte, or any ferro-alloy or chemical extracted therefrom; nitrates of sodium, potassium or calcium; optical glass; palm oil; platinum, plumbago; pyrites; rubber, raw, reclaimed, waste or scrap; scheelite; shellac; sisal; soya bean oil; spiegeleisen; sugars; tanning materials; tin in bars, blocks, pigs or grain or granulated, tin ore and tin concentrates or any chemical ex-

tracted therefrom; titanium, titanium ore or any ferro-alloy or chemical extracted therefrom; tungsten, tungsten ore, or any ferro-alloy or chemical extracted therefrom; vanadium, vanadium ore, or any ferro-alloy or chemical extracted therefrom; wolframite; wool.

NORWAY: PROHIBITED EXPORTS.

Decrees have been issued prohibiting the exportation of the undermentioned articles from Norway:—Antifouling composition containing copper; dry cells, all kinds; fish glue; lead and alloys thereof in any form, materials and goods which contain lead or lead alloys in any substantial proportion; spent oxide from the manufacture of gas; turpentine produced in Norway.

SWEDEN: PROHIBITED EXPORTS.

Exportation of the following goods from Sweden has been prohibited as from November 25:—Compressed ammonia gas; caustic ammonia; chromate of sodium and bichromate of sodium, also chromic acid; tartar emetic and other compounds of antimony, not being colours (the export of "emetic salt" was already prohibited); thorium nitrate and other compounds of rare metallic earths (the export of thorium nitrate was already prohibited); tungstic acid; salts of gold, platinum, and radium; nitrate of lead; chromium sulphate, chromium chloride, chromium sulphochloride, basic, solid or liquid, containing a variable amount of sodium sulphate or sodium chloride; sulphofatty acids, chromate and bichromate of ammonium, chlorine gas dissolved in water, diphosphates, perborates, dinitrobenzol, trinitrobenzol, nitrotoluol, dinitrotoluol, trinitrotoluol, liquid bisulphite of calcium, nitrite of potassium and of sodium, salts of fatty acids and chemical preparations not specially mentioned (in the tariff) consisting of or containing compounds of vanadium, molybdenum, chrome, tin, lead, cadmium, copper, or nickel. Essential vegetable oils and perfumes and cosmetics, the following—Bitter-almond oil, even if artificial; nitrobenzol (mirbane oil); heliotropin, coumarin, musk, and other scented substances, not specified (in the tariff), natural or artificial, for use in the manufacture of perfumery, not being essential vegetable oils; liquid scents and toilet waters containing ether or spirits; hair-dye; laboratory appliances, not specially mentioned (in the tariff), such as test-tubes, retorts, pipettes, and the like.

Nottingham Section.

WASTE LAND AND AGRICULTURE.

Lecturing on the above subject, Dr. E. J. Russell, F.R.S., said that there were in Great Britain some 56,000,000 acres of land of which we cultivated only something like 32,000,000, leaving a balance of 24,000,000 acres which were not cultivated. A little less than half of that—something over 11,000,000 acres—was occupied by towns, cities, railways, and roads and in the nature of things could not be cultivated, but there were some 13,000,000 acres that were not so occupied, that were not fully used agriculturally and might be called either waste land or undeveloped land, whichever expression was preferred. In a country like England, it was presumed that any land that was not cultivated could not be cultivated, or, at any rate, not

profitably. It by no means followed that these 13,000,000 were all hopeless, and in the march of science and the progress that had been made in general agricultural investigation it had often been found possible to deal with land that otherwise could not have been touched, though the process still remained expensive. That night he wanted to show some of the methods for dealing with those lands which in the past had had the reputation of being irredeemable.

The problem of dealing with waste land had always attracted attention from thoughtful people interested in the land, but nothing much had been done in recent years in this country. A great deal had been done in the early days of the last century, but of late there had been so little progress that the extent of waste land had rather increased than diminished. In order that land might be cultivated it was obviously essential that the conditions should be favourable to the growth of crops. Limits might be set either by the climate or the soil; so that generally speaking there were two sets of conditions which had to be taken into account in deciding whether land could be cultivated or not. Unfortunately the climatic conditions seemed to be outside our control altogether. It seemed impossible to alter the amount of sunshine or rainfall. The only way was to attack the other side of the problem and alter the land by proper breeding methods, and produce something which was rather better adapted to the climate than the plants we grew. This was being done to a great extent in several parts of the world, and it was proving effective in circumventing the effect of climate. It was also necessary to determine what soil conditions were needed by the crop. It must have nutrient materials, air, water, and suitable temperature, and there must be an absence of injurious conditions. Any of these that was lacking constituted a limiting factor which prevented the plant from making growth. In any attempt at reclamation the first thing to do was to find out the limiting factor. Taking waste and uncultivated land generally, it would be found that there were some four or five limiting factors. There might be an insufficiency of plant-nutrients, an excess of water or a deficiency of water, a deficiency of temperature or shallowness or insufficient depth of soil.

In the fen district it was frequently necessary that water should be kept out of the land, and this was accomplished by draining on broad engineering lines. A second type of wet land, and one that was far more common, was the case where the land owed its wetness to the fact that the water could not escape. All over the country there were considerable areas of such land, and the proper way to deal with them was to find a way out for the water, which in practice was not always easy. The ancient method was to dig a ditch or open drain at certain intervals so that the proper area was drained. The disadvantage of this method was that the walls of the ditch were apt to fall in. In Roman times it was customary to fill the bottom up with stones and put soil on the top so that the water would find its way down and so get away. Draining, though an old art, was forgotten for a long time; it was not mentioned in British books in the great revival of the 16th century. Gervase Markham, for instance, wrote books on almost every branch of farming, but never one on draining. By the middle of the 17th century, however, it was common, and it was dealt with in Blith's "Improver Improved." But it was not until Puritan times that men began to realise that it was necessary to take levels in order to lay ditches properly.

The next great improvement was to try prevention instead of cure. In the 18th century a young man named Elkington inherited a very wet farm from his father, who was a Warwickshire

farmer; the land lay on the side of a hill, and much of it was very wet and boggy. Elkington described how his sheep died in hundreds and his crops were ruined. Drainage was of no use, and in desperation one day he took a crowbar from a labourer who was digging a trench and drove it with great force into the ground. To his astonishment out ran a stream of water. He then realised that he had struck a spring, and it occurred to him that if he carried his drain right down to the level of the spring so that the water was carried away at the source he would have no further trouble. He therefore sank a deep drain, got down below the spring, and made a broad ditch which carried the water away. He applied the principle to the rest of his farm, and it became beautifully dry so that he was able to cultivate it properly. That led to a considerable amount of draining in the Midlands and other parts of England, and Parliament voted Elkington £1000 for his discovery. From about 1800 to 1850 a very great amount of deep drainage was done, but the very success of Elkington's method proved its undoing. The underlying principles were not really understood, and consequently it was used in all sorts of cases where it was wholly unsuitable, so that it fell into disrepute. Drains were made four or five feet deep with the idea of tapping the sub-soil water before it came to the surface, but often there was no sub-soil water to tap. In some cases the method answered extraordinarily well, in others it failed, and hundreds of thousands of pounds were wasted. It was not realised until many years afterwards that water may come from two sources—some from below and a great deal from rain; so somewhere about 1860 shallow draining was adopted so that as the rain came in it could be got away. Eventually it was realised that both principles contained a great deal of truth.

The next development was pipe drainage, which was followed by the great Government undertakings of the last century. There was no better illustration to be found for the necessity of basing great schemes like these on a foundation of scientific principles. The work was carried out empirically, and a great deal of it wrongly. Some of it proved extremely ineffective and also very costly—anything from £5 to £10 an acre—and in modern days most people had not been able to carry it out; consequently drainage fell for some time into disuse, and probably during the last 20 years there had been very little done systematically. A good deal of our uncultivated land owed its sterility to the fact that the drainage had not been attended to.

A method of drainage which had come into considerable use was by means of the mole plough, which imitated the action of the mole. A steel cylinder with a pointed end was forced through the soil from 9 to 18 inches below the surface, and it was found that this tunnel was remarkably stable; it would last for some years—there were many cases on record where it had lasted from 10 to 15 years without tumbling in. The system had the obvious advantage of cheapness, the cost being about £1 per acre, especially in the Midlands. This promised to be one of the most effective methods where the conditions were suitable—the surface even and the soil free from stones. But, like others, the mole system was not entirely new, there having been mole ploughs in 1800. If, however, any drainage scheme was to be a success the whole of the area must be treated uniformly. One other reform would have to be brought about, and that was to have Drainage Boards whose duty it would be to see that ditches were kept open and water-courses generally kept clear.

Another great trouble in connection with uncultivated land was its dryness. A good deal of

our waste land owed its uncultivated condition to the fact that it was too dry, the water content being insufficient to allow of growth. The old way of dealing with land of this sort was to have recourse to irrigation, which was done in a great many countries. Direct addition of water is one of the very oldest agricultural practices. When history begins there was already a network of irrigation canals between the Tigris and the Euphrates, and the irrigated land was made to bear two or even three crops of wheat a year, yielding a two hundred to three hundredfold return. In England irrigation presented many difficulties, and consequently it was not usually carried out. The difficulty was got over by making full use of the water already present in the soil or which fell upon the soil. Most of our land received at least 20 inches of rainfall, and if that was husbanded there was sufficient for all ordinary crops.

If the overcoming of wetness was the great triumph of our grandfathers, we could reasonably claim for our generation that it had gone a long way towards overcoming the difficulty of dryness. Considerable parts of Britain were affected in this way, especially the sands and gravels of the eastern and south-eastern counties. The old English farmers hated dry soils; they cultivated the loams and clays but left the dry sands as wastes. Nowadays one sought to increase the stock of water in the soil either by adding more water, or by diminishing the losses.

There were two ways of husbanding the water supply. One was to increase the capacity of the soil for absorbing water. If either clay or organic matter were added to these dry soils their power of holding water was increased. One of the great advantages of farmyard manure and other organic matter was that it enabled the soil to do this. There were two or three ways in which organic matter might be got into the soil. One was to grow the crop and dig it in. Another was to grow the crop and allow it to be eaten by the sheep or cattle on the land, so that their excrement would fertilise the soil. That had many advantages, but also the disadvantages that it required considerable capital, and also a knowledge of the management of sheep and cattle, which an arable farmer did not always possess.

There was great difficulty in reclaiming waste lands where there was an insufficient depth of soil. Unfortunately we did not know how to deal with this problem properly. Land of this sort could not be cultivated with our present methods. The only way in which they could be utilised on our present knowledge was to graze them roughly with sheep, and that was done to some extent, but it was exceedingly difficult to know how to get any further. Such land might serve other purposes. Gravel and coarse sand both made good residential sites, golf courses, etc., but our present methods were of little use for the purpose of converting them into agricultural land. There were cases, however, where soil would accumulate through washing down into the hollows or depressions. It was only when the soil became 5 or 6 inches deep that cultivation became possible, otherwise all that could be done was to improve the grass on the higher parts. One case, however, was susceptible to treatment. If the rock was only a thin layer and was underlain by good material there were possibilities of improvement. Cox Heath, Maidstone, was an example. In its original state the soil was so thin that cropping was impossible; it was, therefore, left waste. But underneath the rock lay mineral matter that had in it the making of a good loam. When the rock was removed, and the upper and lower layers joined, a useful soil resulted. Some of the land now was so good that it let at £2 per acre; it had become valuable agricultural land, whilst formerly

it was waste. The removal of rock was, of course, a serious business. This particular reclamation was brought about between 1814 and 1818, when wheat was higher in price even than it is now, and labour was vastly cheaper. Steam tackle might prove simpler, but under modern conditions it would probably be easier to blow the rock out with dynamite—a mode of "culture" which had already begun to appear before the war, and might develop considerably afterwards.

Dr. Russell next dealt with land that suffered from sourness or acidity—a deficiency of lime or calcium carbonate. The remedy was simply that lime or chalk must be added. The old British method was to dig a pit and raise the chalk—a method almost identical with that described by Pliny. Nowadays it was possible to do the work much better and more expeditiously. Ground limestone was just as effective and far smaller quantities could be used. This was one important factor in the increasing of the productiveness of land and bringing into cultivation some of our waste lands.

Lastly, Dr. Russell referred to the question of supplying nutrients to the soil in the form of fertilisers, including nitrogenous, phosphatic, potassic, and organic. Chemists had found that it was possible to use suitable quantities of various substances for different crops and soils, and the problem of fertilising land had simply become one of supplying these substances at low prices. How to get the most useful results depended upon the proper use of these fertilisers. The reclamation of some of the waste land in this country had been brought about by discovering, first, the limiting factor, and, secondly, what was the best and cheapest way of throwing that limiting factor out of action. The cheapest phosphate was basic slag, which had proved of considerable value on certain types of soil where infertility was due to lack of phosphate. In conclusion, Dr. Russell emphasised the point that the problem of waste lands and how to deal with them rested on a definite scientific and economic basis.

DISCUSSION.

Dr. GOODWIN mentioned the Carr lands in the north of Nottinghamshire and on the borders of Yorkshire. There was a large tract of land about Everton Carr which, owing to the excess of water, did not produce a normal or anything like a decent crop. The question of how to deal with land of this character was of very considerable moment, because it had to be utilised by the farmer. Unfortunately the trials that had been made on this land had not been successful. Again, there was a lot of land round about the Dukeries suffering from lack of moisture. Farmers naturally were on the look-out to find some means whereby these limiting factors could be eliminated.

Mr. DROOP RICHMOND referred to the use of limestone, a method which was still employed. It dated back some 2000 years. Dr. Russell had mentioned the difficulty of reclaiming soil which consisted of sand, especially moving sand. Now Egypt was a case in which that had been done, not by the hand of man but by natural causes, and it always seemed to him to be most interesting. Desert land had been converted into fertile land, and it struck him that possibly the way in which this sandy soil had been converted into fertile land by natural causes was worthy of study as to whether something of the same sort could not be done artificially. The waters which formed the river Nile flowed from mountains which consisted very largely of clay, and owing to the dryness of the climate the clay became hard and broken up, so that when the heavy rains came they carried down this clay in a divided state and containing a good deal of colloidal matter. The clay was deposited on the surface of the sand, and when the

rain ceased and the water gradually ran off the clay, containing a good deal of plant nutriment, was left on the surface of the sand. The clay then caked together to a certain extent and prevented the sand from being absolutely pervious. The people who inhabited that country realised the need of water and devised a very simple system of fetching up the water from the river Nile. The same methods were used to-day as were in use 6000 years ago. The water was brought up by a bucket, weighted with a big weight, at the end of a long stick, and the water lifted high enough so that it would run into a channel and thus flow over the land. It was possible that that might be a means of treating sandy soil in this country.

Dr. RUSSELL, in replying on the discussion, said in regard to Mr. Droop Richmond's remarks in reference to the mingling of clay with the sand, that that was done to some extent already in various parts of England, for example in Lincolnshire, where it was done under the name of "warping." Some of our tidal rivers carried an enormous amount of silt, and by a proper system of sluice gates it was possible to let this silty water flow on to the land. That system was also used in the north of Italy, and wherever it could be adopted it was one of the best methods for dealing with light lands. The total of waste land in England was 13,000,000 acres. Unfortunately it was not known how much of these lands could be cultivated. No survey of them had been made; they had not even been properly classified. These were facts which made all political discussion of the subject rather artificial. The question was whether this land was to be made as productive as it might be or whether it was to be left to look after itself. He had very little doubt as to what the answer of the community would be after the war: it would be decided that no land was to be left waste if it could be cultivated. We could not run the risk of having uncultivated or undeveloped land.

Yorkshire Section.

Meeting held at Queen's Hotel, Leeds, on Monday, November 19th, 1917.

PROF. J. W. COBB IN THE CHAIR.

THE EFFECT OF VARIOUS "THINNERS" ON THE DRYING OF LINSEED OIL, AND THE ACTION OF DRIERS ON TURPENTINE.

BY A. WOODMANSEY, B.SC., A.I.C.

Divergent opinions have been expressed as to the relative value of turpentine and other solvents in the drying of linseed oil. Discussing their respective merits when present in a paint, Toch ("The Chemistry and Technology of Mixed Paints," pp. 103 and 112) says:—"Entirely too much stress is laid upon the value of turpentine as a paint vehicle and the sooner the chemist and the consumer realise that turpentine is simply an auxiliary the sooner will better substitutes be used . . . after all any solvent, whether it be benzene, turpentine, naphtha, benzol, or acetone, is nothing but a solvent and evaporates completely leaving the other vehicles to protect the paint." On the other hand, Jennings ("Paint and Colour Mixing," p. 8) states:—"It is very important that the turpentine used should be pure. American spirit is mostly used. Owing to its price it is sometimes adulterated, with disastrous effects to the paint." These are

types of the diametrically opposed opinions which are so often met with; they are quoted because the volumes referred to are largely consulted by those interested in the practical side of painting.

Experiments were conducted to decide how far different thinners were instrumental in increasing the weight of a drying film of oil under conditions similar to those obtaining in practice.

Effect of thinners on linseed oil.

A weighed quantity of the oil was spread over Petri dishes and 1 c.c. of thinner pipetted in as required, solution being effected by gently agitating the dish. The dishes were then exposed to light and air for six days, a longer period not materially affecting the result. No use was made of the desiccator in any of the weighings, and as no hygroscopic change in weight of an empty dish was apparent in this series a correction was unnecessary. In making the calculation the residue left by 1 c.c. of thinners was deducted.

As pure linseed oil increased in weight very slowly, and in order to approximate to practical conditions, 1% of manganese resinate was dissolved in the raw oil, by warming with a small quantity of oil and then adding the bulk.

Little or no increase in weight was observed over the blank (oil without thinner) when chloroform, carbon tetrachloride, benzene, petroleum ether, or a light turpentine substitute was used, but a very pronounced increase occurred in the case of turpentine or a substitute of higher boiling point.

The following figures may be cited as one experiment:—

Boiled oil, sp. gr. 0.919.

Raw oil (1% Mn resinate), sp. gr. 0.933; iodine value 190.

Turpentine (American), sp. gr. 0.866; b.pt. 159°–160° C.

Substitute (a petroleum fraction), sp. gr. 0.784; b.pt. 140°–198° C.

Petrol (redistilled and collected in two fractions), sp. gr. 0.712, b.pt. 80°–140° C. and 140°–155° C.

	Weight of oil, gm.	Increase in weight, %
Boiled oil	{ 0.3463 0.5565 0.4312	{ 5.95 5.48 5.96
Boiled oil + 1 c.c. CHCl_3	{ 0.3993 0.4465	{ 6.03 5.44
Boiled oil + 1 c.c. turpentine	{ 0.4500 0.5049 0.4226 0.3584	{ 12.70 13.29 10.81 13.34
Boiled oil + 1 c.c. petrol (b.pt. 80°–140° C.)	{ 0.3947 0.4202	{ 6.43 6.66
Boiled oil + 1 c.c. petrol (b.pt. 140°–155° C.)	{ 0.3935 0.4338	{ 8.76 7.93
Boiled oil + 1 c.c. substitute	{ 0.4744 0.3945 0.6169	{ 14.65 15.56 14.89
Raw oil + Mn resinate	{ 0.1476 0.1911 0.1418	{ 10.03 9.94 10.15
Raw oil + MR + 1 c.c. CHCl_3	{ 0.2330 0.1901	{ 9.94 9.36
Raw oil + MR + 1 c.c. turpentine	{ 0.2259 0.1708	{ 21.64 23.47
Raw oil + MR + 1 c.c. petrol (b.pt. 80°–140° C.)	{ 0.2239 0.1856	{ 8.84 10.13
Raw oil + MR + 1 c.c. petrol (b.pt. 140°–155° C.)	{ 0.2486 0.2000	{ 11.66 12.59
Raw oil + MR + 1 c.c. substitute	{ 0.2320 0.2013	{ 21.38 18.58

From the point of view of increase in weight of the oil-film the sample of turpentine used in the above experiments possessed no advantage over a substitute of high boiling point. In drawing up a specification for substitute it would not be wise to require an upper limit above 200° or 210° C., since the drying process would then be too prolonged.

A plausible explanation of the action of a thinner is that it causes the oil to remain liquid and so, by preventing premature formation of an impervious film, enables a greater oxygen absorption to take place in the mass of the oil. A more volatile thinner disappears before such effect is produced. In the case of the substitute this explanation is probably the correct one. Further work with turpentine, however, proved it to be only partially capable of meeting the facts. While the substitute requires several days to evaporate, turpentine largely volatilises in a few hours. We should then expect the substitute to exercise a much greater effect, an anticipation by no means borne out. In some experiments with turpentine also an increase was recorded greater than the theoretical increase, calculated on the basis $\text{O}_2 = \text{I}_2$ (Ingle, this J., June 30, 1913). This increase was finally traced to the turpentine itself, which "resinised" in the presence of the catalyst. No explanation is offered here as to the nature of the resination, though oxidation plays an important part. The gradual atmospheric oxidation of terpenes is well known. Manganese resinate, lead resinate, and red lead were all found to act in the same way towards turpentine, the first named being the most effective.

Effect of red lead on turpentine.

Into each of two weighed 220 c.c. beakers was pipetted 25 c.c. of turpentine (sp. gr. 0.804, b.pt. 156°–163° C.) and 0.7488 gm. of red lead was added to one of them. They were shielded from dust and the contents allowed to evaporate.

	Weight of turpentine.	
	Alone.	In contact with red lead.
	grms.	grms.
In 20 days	11.2019	13.8739
In 29 days	7.1578	10.3709
In 49 days	1.5708	6.0453

The great difference in the amounts and the high viscosity of the second residue in comparison with the first were apparent.

Effect of manganese resinate on turpentine.

Three further points were brought out in the following series of results:—

(1) Samples of turpentine (all obtained from painters' supplies) showed marked differences in the net weight of residue left on evaporation, if the experiments were carried out within a short time after redistillation. After a month these were comparable in magnitude.

(2) Each sample showed a progressive increase in the amount of residue according to the lapse of time after redistillation, and also the "potential" resinisation, as indicated by the weight of residue without driers, gave, for a particular sample and in the earlier series, some idea as to the effect of the addition of a catalyst.

(3) Petri dishes of two sizes were used in duplicate, the larger one of 2½ in. diam. and the smaller of 2 in. diam. The higher result of a pair was observed in most cases to be obtained with the smaller dish, i.e., a lesser surface conducted to slower evaporation and consequently more prolonged contact with the catalyst.

Three samples of turpentine were freshly distilled on the date of the first set of weighings.

- A—Sp.gr. 0.8677; b.pt. 158°—161° C.
 B—Sp.gr. 0.8640; b.pt. 156°—163° C.
 C—Sp.gr. 0.8655; b.pt. 157°—160° C.

The manganese resinate (approx. 1%) was dissolved in benzene, filtered, and measured into the weighed dishes by means of a burette, and the thinners were then introduced by the pipette. The quantity used was 1 c.c. of each. After four days the residues were weighed and the results tabulated. The turpentines were allowed to "age" for 14 days and the series repeated without another redistillation, and again a third time after a further 12 days. The turpentine substitute was used for the purpose of comparison. It had not been redistilled for some months (sp. gr. 0.784, b.pt. 140°—198° C.).

Mr. JAMES E. BEDFORD asked if the author had given attention to the durability and preservative qualities of oxidised linseed oil under different degrees of oxidation. Was the preservative power increased by further oxidation or otherwise?

Dr. H. INGLE said that with regard to the oil alone, the results obtained in small dishes could not be taken as a measure of the absolute gain in weight by complete absorption, as the film was too thick. Theoretically an oil having an iodine value of 190 should increase about 24% in weight. The author had obtained by thinning with turpentine up to 23.47%, which was very near that figure, and higher than usually obtained with oil alone by the plate method (Weger, 18%). It was shown in the paper that too volatile diluents, by allowing the formation of a skin of oxidised oil on the surface, prevented the lower portions from drying; thus the lower the boiling point of the turpentine

The resultant film formed by turpentine and driers, at first "tacky," set at length with a firm varnish-like appearance.

A consideration of these data led to a comparison of freshly distilled turpentines in conjunction with raw linseed oil (containing manganese resinate) by the preceding methods. As far as the experiments were taken, confirmation was afforded that turpentine "B" was very much less effective than turpentine "A" in producing an increase in weight.

In conclusion, reference may be made to the interpretation of the tests of painted fences in North Dakota (1906) and the assertion of the experienced painter that turpentine is better than a substitute. It may be suggested that this opinion is based on the added quality imparted to the dried paint by the varnish-like film due to turpentine and drier.

Summary.—The presence of a "thinner" normally increases the weight of a drying oil-film.

The magnitude of the increase is in a measure inversely dependent upon the volatility of the thinner. An additional increase may be brought about in the case of turpentine by reason of the "resinisation" due to the action of the drier on the turpentine.

DISCUSSION.

The CHAIRMAN said that the author had set out a number of results which were likely to be useful, without the complication which would have accompanied chemical speculation as to their complete explanation.

the less the increase in weight. Old turpentines gave a greater increase than new ones. He (Dr. Ingle) thought that this was due to the oxidation (resinification) on keeping the turpentine. Referring to a rough test of his, in which the time taken by a strip of paper to dry after immersion in the liquid was noted, he had always considered that the turpentine (not substitutes) which dried the quickest was the best, but evidently the intermediate ones were better as they allowed of more molecular movement before a skin was formed.

Mr. GEORGE WARD said that turpentine had an advantage over a substitute because the former gave a varnish-like finish. Had the author carried out any experiments with wood instead of glass? The resination of turpentine made it better than a substitute for painters' use.

Mr. JAMES MILLER said that the amount of increase in weight on evaporation was not necessarily a good criterion. He had in mind a paint which would not dry, and on examining the turpentine used it was found that on evaporation it left a resinous, sticky residue; evidently the turpentine had resinified owing to age. He agreed with Dr. Ingle's method of testing turpentine. He thought that a new turpentine would yield a better film than an old one.

Mr. WOODMANSEY said, in reply to Mr. Bedford, that he had presented these effects of thinners on oils from the point of view of increase in weight only, and could not say how varying degrees of oxidation affected durability. Regarding linseed oil and not specially in connection with thinners, some

tentative experiments on durability and the other qualities which, though of paramount importance were least amenable to direct measurement, were being carried out. He agreed with Dr. Ingle's theory as to the assistance afforded by volatile diluents. Films of oil of thickness varying between very wide limits had been tried, and the results were found to conform with those quoted. He had not carried out any quantitative work using wood surfaces. He thought hygroscopic difficulties might arise. Mr. Miller's experience of the non-drying property of some old samples of paint had been met with in the case of certain old turps varnishes.

The author read the following extracts from a letter he had received just before the meeting from Mr. W. Gathorne Young:—" . . . I made some determinations of increase of weight on drying of raw linseed oil with and without addition of turpentine spirit, nearly twenty years ago, in order to refute the claims of certain people, who wished to sell deodorised petroleum spirit . . . for use in place of turpentine spirit, that the petroleum spirit was just as good in every way as turpentine spirit and much more economical. . . . I presume you are aware that if you keep a small volume of turpentine spirit exposed to a relatively large volume of air in a confined space, the turpentine spirit resinifies progressively until, if kept long enough, its consistency may become thicker than that of crude rosin oil, and thin films of it will become solid. You can show this very well by putting 20 c.c. of turpentine spirit in a closely stoppered litre flask and allowing it to stand for twelve months at rest, exposed to sunlight. I have . . . always attributed it rather to polymerisation of the terpene than to oxidation. Of course, the increase in weight of linseed oil on drying in presence of turpentine spirit is a different matter."

NOTE UPON THE RATE OF SOFTENING BY THE LIME-SODA PROCESS.

BY JAMES W. WOOD, M.S.C.

The lime process of softening water is based upon that originally devised by Clark, that is, by the addition of caustic lime to a water containing calcium bicarbonate. The water is softened by the precipitation of calcium carbonate, part being produced from the bicarbonate originally in solution and part from the added lime.

One of the first plants employed for utilising this reaction was the Archbutt-Decley plant. For dealing with waters of variable composition and for simplicity the plant was excellent, but in towns, where space is usually limited, the plant occupied too much ground space and moreover it was not sufficiently flexible to meet varying demands for softened water.

In continuous softeners water and reagent are run into the bottom of a large tank, and by taking off water from the top it is possible to obtain a reasonably clear water, provided that the velocity of the water through the tank is not so great as to carry over the precipitate. The flow of water, however, to secure this object must be abnormally slow and ample time is thus allowed for chemical reaction and precipitation to take place. If these softeners are used in conjunction with a filter, however, it is not necessary to wait for the separation of the precipitate to take place by gravity, and the velocity of the water can be greatly increased. Theoretically, it can be increased indefinitely and is only limited by the efficiency of the filter and the rate at which the reactions can take place. The latter is held in many quarters to be quite a negligible time, but the figures given below show that it is other-

wise. This is of considerable importance at the present time, when it may be necessary to work existing softeners beyond their rated capacity, and unless the softeners have been designed with a liberal margin trouble will ensue. Such has been the experience of the author.

The water dealt with is a typical one of the London area with a hardness of 22 to 25 parts CaCO_3 per 100,000. The hardness is almost entirely due to calcium salts, about two-thirds of this being temporary and one-third permanent hardness. Magnesium compounds are present but only in small quantities. For certain purposes water with a hardness of 8 to 9 parts per 100,000 was sufficiently good and therefore softening with lime alone was first experimented upon.

Experimental.

Laboratory tests were made in a bottle of 10 litres capacity, the calculated amount of saturated lime water being added. At intervals portions were withdrawn and titrated with $N/10$ hydrochloric acid as rapidly as possible, especially in the early stages of the experiment. The assumption is made that particles of calcium carbonate which have reached such a state of aggregation as to be no longer effective as hardening agents are not affected appreciably in the short time required for a titration, by an acid of such low concentration as $N/10$ hydrochloric acid.

I have devised and upon several occasions shown a lecture experiment to illustrate the course of the reaction. The water to be softened is placed in a vessel about a foot deep and 5 in. in diameter, through which a powerful beam of light can be projected in a vertical direction by means of a reflector. At first the water is perfectly clear and the beam is not visible as it passes through the water, nor are conditions changed upon the addition of the theoretical amount of clear saturated lime water. With water at ordinary room temperatures the water remains clear for two or three minutes, after which a slight opalescence appears, which gradually becomes more marked until the whole vessel becomes filled with a milky liquid, but no individual particles can be seen. After this stage the particles grow either by the addition of fresh material or by segregation, but in any case they appear to become much fewer in number and the mixture acquires the character of a true suspension with particles of appreciable size, the water between them being perfectly clear. I have said that the particles become visible individually; it would perhaps be more correct to say that they become visible as secondary sources of radiation as in the ultra-microscope. I have made several unsuccessful attempts to measure the size of the particles with the ultra-microscope, trouble being experienced owing to the fouling of the cell walls with the precipitate. After the particles have reached appreciable size they slowly settle, leaving the upper portion perfectly clear. It is interesting to note that for fully three minutes, *i.e.*, the time during which the water remains clear, the determined hardness corresponds almost exactly with the sum of that originally present and that due to the added lime. The liquid is probably supersaturated with regard to CaCO_3 . I have never been able to prolong the supersaturation period beyond five minutes at ordinary temperatures, but I am confident that with care it might be done.

Unless the vessels are scrupulously clean, and especially if an experiment has previously been carried out in the same vessel, the time for the commencement of precipitation may be reduced considerably, whilst if a little wet precipitate be added from a previous experiment it is practically impossible to detect the clear stage and very

little of the milky stage owing to rapid precipitation and growth of the precipitate.

The curve given shows the course of softening in a typical experiment at ordinary temperatures, the curve being of ordinary hyperbolic shape. It will be seen that it takes some 90 minutes to complete the softening to a reasonable degree,

Removal of temporary hardness at 12.7° C. by use of lime alone.

Note.—Total hardness at any point = Temp. hardness + 7°.

i.e., it is inadvisable for the water to take less than an hour and a half to pass through the softener under these conditions. As the water in a plant working at a normal rate usually takes longer than this to pass through a softener the water is usually sufficiently softened at the outlet.

It has been my experience, and the experience of others, that if the velocity is increased above this rate the softening is completed in feed-water heaters or boilers with attendant troubles.

The question now arises as to whether or not the reactions can be hastened under such conditions as obtain in commercial work. I have made use of the usual means adopted for increasing the speed of reaction in chemical work. Raising the temperature is the easiest means to adopt. It is found that raising the temperature from 15° to 20° C. increases the rate of reaction most markedly, but the results have not been sufficiently concordant, and one can only say that the time required is approximately reduced to two-thirds. Softeners are now frequently heated by exhaust steam or condensed water, and in that light are looked upon as heat recoverers or collectors of water not requiring treatment, the useful function of aiding reaction being overlooked. It is merely a question of introducing the steam or hot water at the right point to use it most effectively for this purpose. The addition of excess of reagent increases the rate of softening, but with lime alone this course cannot be well adopted as the use of an amount lime beyond that actually required would again render the water hard, and it is not unknown for water to leave a softener harder than it entered owing to the injudicious use of excess of lime.

The rate of softening by soda alone has not been determined, but there is a marked difference in speed according to whether the lime and soda are mixed immediately before entering the water or whether they enter the water at different points and afterwards mix. This is probably due to the almost immediate precipitation of calcium carbonate in the relatively concentrated solutions of reagents: the calcium carbonate then acts as a "seeding out" agent as already described.

The time required for lime-soda in correct proportions for the water is 50 to 60 minutes as against 90 minutes for lime alone under similar conditions. The addition of extra lime, corrected by extra soda, may further reduce this to 40 minutes, but there is then trouble with excessive amount of solids remaining in the water. A better means would be found in working a larger plant at its normal rate with normal supplies of reagent. Lastly, filtration is a most useful means of acceleration. The ordinary filter most probably acts by providing a surface to which the precipitate may adhere. It is reasonable to suppose therefore that after a filter has been in use for some time the filtering medium becomes coated with precipitate, which then acts as a nucleus upon which further particles—and particularly the smaller particles—may grow. This much is certain, that a filter which has been in use for some little time can be worked at a greater speed and will deliver clearer and softer water than a new filter. As soon as the precipitate becomes loose or too thick upon the surface of the filter, the current of water washes it off and the outlet water becomes turbid again. In using exhaust steam and condensed water it must not be overlooked that a greasy water exerts a marked retarding influence upon the rate of softening.

I am indebted to the Chemical Department of the Battersea Polytechnic for providing facilities for carrying out experiments. The lecture experiment described has been frequently shown to students at that Institution.

DISCUSSION.

The CHAIRMAN said that he had never realised before so clearly how long it might take to precipitate calcium bicarbonate by lime-water. He was doubtful of the resisting power of precipitated calcium carbonate to hydrochloric acid over the very finite period of time required for a titration, but no doubt Mr. Wood had assured himself of the validity of this assumption.

Mr. W. MCD. MACKAY said that the author's device for the optical examination of the rate of precipitation was excellent and might be applied with advantage in other directions. His experience agreed with that of the author, that a slight excess of reagents gave quicker precipitation. The author was working with water lower in magnesium salts than was generally found in the Leeds district; the usual experience was that as the amount of magnesia rose the difficulty of softening increased. He thought it would generally be found that a greater proportion of the magnesium salt (as compared with the lime) remained in the softened water. The author's observation that old precipitate or the use of a vessel for softening that had already been used for the purpose, gave better results, was borne out in practice. His (the speaker's) experience was that in water softening better results were obtained on the works scale than in the laboratory, where naturally clean vessels were used. On the question of quick sedimentation he had found that a tall cylindrical vessel put in a sloping position gave quicker sedimentation than when the vessel stood upright. This observation was due to Mr. Miller after he (the speaker) had

used the sloping tank on works scale for quick sedimentation because of other advantages.

Mr. B. G. McLELLAN said the author had made some interesting statements regarding the length of time required for "completion" of the softening reactions with a moderately hard water, and with the theoretical quantity of chemicals; with very hard water, above 70 parts per 100,000 total hardness, this period was even greater, and plants were often designed which were inadequate in this respect. The result was that the softening was completed on the way to the boilers where it was least desirable. Further research on the reaction velocity of the lime and soda softening process was required. The increase in temperature mentioned by the author as a means of hastening completion was so slight that the method might be adopted even by those who require a cold softened water. The Archbutt-Deeley process of employing old sludge for hastening reaction and settling was interesting; he had tried to adapt this idea to a continuous softener, but so far without success. The idea of a sloping surface mentioned by Mr. Mackey was, he understood, embodied in the French "Desrumaux" plants.

Mr. MACKEY said that he did not think the sloping tank principle was used in the "Desrumaux" system. He thought there was a spiral arrangement for dealing with the precipitate. In the Archbutt-Deeley process his recollection was that the clear or almost clear water was pumped from the upper part of the tank in about twenty minutes after the blowing up of the old precipitate; this showed that the precipitation process was considered to be complete within say half an hour after adding the chemicals.

Mr. WOOD said in reply that if dilute hydrochloric acid be added when the precipitation had reached the "milky" stage, immediate clearing took place, but later on no appreciable change was apparent in the time required for a titration, the inference being that these larger particles were not attacked to any marked extent. The figures given for the removal of hardness by lime alone did not refer to total, but to temporary hardness. It was not possible, using theoretical quantities of reagent, to push the hardness below 3.5°. By the use of excess of soda, however, it was possible to reach 2.6°, but owing to the excess solids in the water giving rise to "priming" there was no advantage in so doing. Softening with the "theoretical" amount of lime as usually calculated was slow. This really amounted to a deficit of lime, as further lime was required to combine with free carbon dioxide in the water, to precipitate part of the magnesium permanent hardness and to allow for impurities in the lime. By adding successive amounts of lime a point had been found at which the hardness was a minimum, and the amount of lime required was in excess of that calculated in the ordinary way. Most of his experiments had been confirmed on the plant as well as in the laboratory.

Communication.

ON THE PERMANENT SET OF RUBBER.

BY O. DE VRIES AND H. J. HELLENDORF.

In the mechanical testing of rubber a study is often made of the permanent set or some other form of set or deformation. A further study of this property seemed desirable, in the first place because little is known of its relationship to other mechanical or chemical properties, so that it is still an open question whether the determination

of permanent set ought to be included in the routine testing of raw rubber or not; in the second place because the permanent set being admittedly dependent upon the state of cure of the vulcanised rubber (the set for instance for rubber-sulphur mixtures being greatest for undercured material and diminishing as the cure proceeds), no definite data have been published up till now to reveal the numerical side of this relationship.

Schidrowitz has laid full stress on the fundamental importance of an exact determination of the state of cure in all mechanical tests on vulcanised rubber and of comparing mechanical properties only for the same or for a comparable state of cure*; much confusion in the literature must be ascribed to neglect of this point. In the present paper we intend to bring forward some data bearing on the study of the relationship between permanent set and state of cure, and between the permanent set at a standard state of cure and other mechanical properties of rubber, especially the "type" after Schidrowitz.

Experimental.

For vulcanisation all samples were mixed in the proportion of 92½ parts of rubber and 7½ of sulphur and vulcanised in steel frames between steel plates in live steam at 148° C. for different lengths of time.† To determine the state of cure some of the rings of one slab were tested on the Schopper stretching machine, whilst others were used for the determination of permanent set.

To express the state of cure three methods might have been chosen, viz., (1) the time of cure at 148° C.; (2) the coefficient of vulcanisation; (3) the position of the curve obtained on the Schopper stretching machine, which we express by giving the length at a load of 1.30 kilos. per sq. mm. (which is determined graphically, by plotting on millimetric paper the average breaking point of the rings tested, and taking the length at a load of 1.30 kilos. by using the slope of the final part of the curve, taken directly from the graphs drawn by the testing machine). For our present purposes we chose the third method, since the second involved a large number of tedious sulphur determinations, and gives figures which run exactly parallel to the "length at 1.30 kilos."; the first is not so exact, as small errors in temperature during vulcanisation are not eliminated.

For the determination of the permanent set we use the method of the "Ryksvoorlichtingsdienst" at Delft. Rings of the same dimensions as used on the Schopper stretching machine (inner diameter of the rings 44.4 mm., breadth 3.75 mm., thickness 5 mm.), are stretched on a specially made glass plate 8 mm. thick, with rounded edges, and cut obliquely at one corner to facilitate putting on and taking off the rings. The length of the glass plate is so chosen that the rings are stretched to five times their original length (elongation four times original length). Before being put on the glass plate the rings are measured on a Schopper testing machine for determination of permanent set, the total weight used for stretching being 200 grms. The original length under this weight of course varies somewhat with the state of cure, the readings differing about 1 mm. After remaining on the glass plate for 24 hours the rings are taken off and six hours later the length is again determined. We take the precaution to put the ring on the glass plate in a fixed position with a mark (series number of the ring) in the middle between the edges, and to put it on the testing machine in exactly the same position before as after stretching, with the mark below. This tends to avoid errors due to small differences in the breadth of the ring

* The Rubber Industry, 1914, p. 212; Rubber Recueil, Batavia, 1914, p. 373.

† For further details see India Rubber Journal, 53, 101.

or to slight unevennesses of the inner surface and to the greater strain the ring has undergone on the edges of the glass plate. The original length (half of the inner circumference) of the rings being 70 mm., a difference of one-half in the permanent set means only 0.35 mm. difference in the measured length or elongation, so that only the average of a fair number of determinations is reliable; the more so as the reading of the length before and after stretching is always more or less conventional, the ring keeping on stretching slowly over several tenths of a millimetre under the applied weight of 200 grms., and even the way in which the weight is applied (smoothly or abruptly) having influence upon the result. We read the length immediately after the ring has come to apparent rest after letting down the weight slowly. The elongation calculated as percentage of the length before stretching (70 mm.) gives the permanent set.

Relationship between permanent set and state of cure.

That the permanent set varies with the state of cure and is greater for undercured than for longer cured rubbers is a well known fact, which needed no further corroboration. But no numeri-

cal data were available as to the relation between permanent set and state of cure, enabling one, for instance, to calculate the permanent set for a chosen (say a fixed standard) state of cure from determinations on a sample cured differently. We therefore collected sufficient lots of homogeneous samples of various types of rubber and determined the permanent set for each of them in several states of cure. Fig. 1 gives four of the curves so obtained, the state of cure being expressed as "Length at a load of 1.30 kilos." (see above). No. 41, a first latex crêpe rubber, has a low permanent set, whilst No. 117 C, a bark crêpe, shows high figures in all states of cure.

Table I. contains data for 15 typical samples of ordinary plantation rubber. From the data of the ordinary types (Nos. 1—10) so obtained we calculated the slope of these curves in the neighbourhood of 990% and of 1025% (see columns 7 and 8 in Table I.) and found the following average values: for a state of cure expressed by a "length at a load of 1.30 kilos." of 990%, the increase in permanent set is 0.08 for an increase of 10 in "length at 1.30 kilos.;" for a state of cure expressed by a "length at a load of 1.30 kilos." of 1025% the increase in permanent set is 0.15 for an increase of 10 in "length at 1.30 kilos."

From these figures the lowest curve in Fig. 1 is constructed, giving the average increase in permanent set for different states of cure. For the correction and reduction of permanent set at different states of cure the following table may

FIG. 1.

Permanent set for different states of cure, four samples from Table I.
Below: average slope of ten samples (Table I.).

be used, which gives in the first column the state of cure at which the permanent set was determined, and in the second the correction to obtain the permanent set at our standard cure (length at a load of 1.30 kilos. = 990 %).

TABLE II.

Length at 1.30 kilos.	Correction in permanent set.
1040	- 0.65
1020	- 0.48
1020	- 0.33
1010	- 0.20
1000	- 0.09
990	—
980	+ 0.07

By simple calculation similar tables can be drawn up for the reduction to other standard states of cure.

The above curve and Table II. give the *average* from our determinations; our experimental data, however, are not sufficient to determine whether the curves in Fig. 1 run parallel in all classes, i.e., if the decrease in permanent set for the same increase in state of cure is the same for all types of rubber. It might be that for rubbers with a high permanent set the curve is somewhat steeper; a large number of determinations would be necessary to settle this point, which we did not deem to be of sufficient importance to justify the amount of work it would involve being undertaken at present.

Relation between permanent set and "type" after Schidrowitz.

The determinations of permanent set for fifteen samples mentioned above enabled us to fix the permanent set of these samples at our standard state of cure, for which we chose the cure at which the length at a load of 1.30 kilos. is 990 % of the original. The values are found in

the ninth column of Table I. These values show a close relationship with the property called "type" by Schidrowitz, which expresses the slope of the stress-strain curve as obtained on the Schopper-machine for high elongations and is calculated by means of the formula: *

(Length at a load of 1.04 kilos. — length at a load of 0.60 kilo.) $\times 0.4$.

Schidrowitz attaches high importance to this factor in judging the quality of the rubber, a low figure for "type" meaning little stretching by a fixed increase in load and therefore a high quality of rubber.

In Fig. 2, the values of permanent set at our standard state of cure are plotted against the "type" of the samples after Schidrowitz: it

Fig. 2.

Relation between permanent set at standard state of cure, and slope of type of the stress-strain curve after Schidrowitz (see Table III.).

Below: lower part of the curve, representing the normal types of rubber, on an enlarged scale.

will be seen that the points lie very approximately (within the limit of 0.2 in permanent set) on a curved line, which for ordinary rubber with a figure for type of 34 to 40 is nearly a straight one. The following values are found for the line representing the average:

TABLE III.

Type.	Permanent set.
34	1.9
35	2.2

42	4.75

From Table I. it will be seen that the greatest deviations from this average are 0.38 in permanent set for sample 220 (imitation Para-ball) and 0.26 for sample 117 C (bark crêpe), whilst for the

* Schidrowitz and Goldsborough, India Rubber J., 51, 505.

other samples the average deviation is only 0.12 and does not exceed 0.2. As "type" is only determined with intervals of 1, and the permanent set even with a large number of rings is subject to a rather large experimental error, the relation between permanent set and type may be regarded as very close.

To test this relationship further we may make use of our determinations of permanent set on a number of other samples (Table IV.). As the determinations were not all made at the standard state of cure, we reduced the values in column 5 of Table IV. to those of column 7, using the correction from Table II. where needed. In plotting the values so obtained in Fig. 2, it will be seen that for 29 samples the figures do not differ from the curve by more than 0.3 in permanent set, the average difference being ± 0.11 . As the number of rings from which the permanent set is derived was seldom more than 2 or 3, this deviation must be regarded as lying well within the limits of experimental error. Four samples (153 O, P, S, T) show a difference of +0.34 to +0.58; these are smoked sheet coagulated by a solution in water of the gases from burning sulphur. Only four samples show a very marked difference, viz., Nos. 386 and 524 (crêpe prepared from slab rubber) +0.80 and +1.25, No. 33 B (crêpe more than 1 cm. thick) +1.07, and No. 32 (imitation Para-ball) +1.72.

It is interesting to note that these four samples all contain more serum-substances than ordinary estate rubber and are rapid curing; No. 220 however, the imitation Para-ball mentioned in Table I, shows a smaller deviation (+0.38) than that found for this sample No. 32. It may be remarked that sample 134 E, first clot obtained by partial coagulation, which contains more nitrogen, resin, and ash than ordinary crêpe, shows the normal proportion between permanent set and type.

Conclusions.

The permanent set of vulcanised mixtures of 92½ parts of rubber and 7½ parts of sulphur, determined by stretching rings for 24 hours to five times their original length and reading the set after six hours' rest, decreases with advancing state of cure, the average decrease being expressed by the lower curve in Fig. 1 and by the figures in Table II. These data allow one to calculate the set at our (or any other) standard state of cure from determinations at other states of cure.

The permanent set for our standard state of cure shows a very close relationship with the property called "type" by Schidrowitz, being the slope of the stress-strain curve for high elongations. This relationship is expressed by Fig. 2 and

TABLE IV.

Table III., and takes the form of a curve, which for ordinary estate rubbers with a figure for "type" of 34 to 40 may be regarded as a straight line. Only for some special cases of rubber with an abnormal content of serum-substances (imitation Parahall, slab rubber after Eaton, rubber completely dried as very thick crêpe) marked deviations were found.

As the "type" in ordinary routine testing of

raw rubber can be determined in the same operation as tensile strength, a separate test for permanent set—when using the above-named mixture of rubber and sulphur only—is superfluous for ordinary samples; only in the case of rubber prepared by special methods a deviation from the above given relationship may occur and lead to valuable conclusions.

Central Rubber Station, Buitenzorg.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron 8, Paris (3s.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Design and manipulation of gas furnaces. Forshaw. See 11A.

PATENTS.

Heating and boiling pans, heated calendering rollers, heating tables and like apparatus. H. V. Senior, Bracebridge Heath, Lincolnshire, Eng. Pat. 110,803, Nov. 4, 1916. (Appl. No. 15,767 of 1916).

AN oil bath or jacket, provided with an extension to maintain an approximately constant level, is interposed between the boiling pan and the source of heat; the area of oil surface in the extension is large compared with the annular area of the oil bath. The gas and/or the air are preheated on their way to the burners by being passed through coils or around annular partitions in the space between the oil bath and the outer casing. Means are provided for automatically controlling the temperature of the oil.—W. H. C.

Distillation of liquids. O. Stalhane and O. O. Kring, Ludvika, Sweden. Eng. Pat. 110,821, Nov. 27, 1916. (Appl. No. 16,998 of 1916.)

THE water or other liquid is fed into the constant level device, 10, and passes down the pipe, 9, into the reservoir, 7. It then flows up the pipe, 6, into the still, 1, where it is vaporised by the electric heater, 2. The vapours pass out of the aperture, 16, into the outer condensing chamber, 4, and thence through the pipes, 12, into the reservoir, 13.—W. H. C.

Evaporating apparatus. Kestner Evaporator and Engineering Co., Ltd., J. A. Reavell, and W. G. Mann, London. Eng. Pat. 110,921, Oct. 6, 1916. (Appl. No. 14,208 of 1916.)

EVAPORATING apparatus, more particularly for use in de-salting saline solutions, comprises a tubular

heater and a vapour separator. Valved pipes connect the top of the heater with the vapour space of the separator, and the bottom of the heater with the separator at a point just below the liquid level. To ensure better circulation and quicker heating from the cold, an additional valved pipe is provided connecting the bottom of the separator with the pipe leading to the bottom of the heater, or directly with the bottom of the heater. The valve in this pipe is closed after the liquid in the system is heated.—W. F. F.

Refrigerating process and apparatus. C. Cortesi, E. Prassone, E. Erani, and A. Contin, Rome. Eng. Pat. 103,312, Jan. 13, 1917. Under Int. Conv., Jan. 13, 1916. (Appl. No 655 of 1917.) Addition to Eng. Pat. 1853, Feb. 5, 1915.

IN a refrigerating apparatus of the type described in the principal patent, liquid is evaporated in a boiler, the vapour operates an ejector and is condensed, and the condensed liquid returns to the boiler by gravity. Part of the liquid from the condenser circulates through an expansion coil where it is vaporised, and returns to the condenser through the ejector which causes the circulation. Two liquids of different specific gravities which do not mix are now used, the heavier, such as mercury or water, circulating through the boiler, ejector, and condenser, and the lighter, such as ether or benzol, circulating through the condenser, expansion coil, and ejector.—W. F. F.

Pulverising mills. The Raymond Brothers Impact Pulverizer Co., Assignees of R. A. Lachmann and W. B. Senseman, Chicago, Ill., and A. W. Raymond, Evanston, Ill., U.S.A. Eng. Pat. 101,962, July 24, 1916. (Appl. No. 10,411 of 1916.) Under Int. Conv., Oct. 23, 1915.

THE discharge port of a pulveriser is provided with a regulator to control the fineness of the product, consisting of a series of radial arms mounted on a shaft by which it is rotated and along which it can be moved to or from the conical outlet so that the size of the opening is varied. A current of air is passed through the pulveriser to remove the product.—W. H. C.

Grinding mills and the like. W. A. Cloud, London. Eng. Pat. 110,816, Nov. 23, 1916. (Appl. No. 16,817 of 1916.)

THE materials are passed between a number of rotary discs which alternate with fixed discs and are surrounded by a casing. The discs have rows of grinding pins of square or angular cross section mounted on their faces, and the discs themselves are of increasing diameter and set closer together from the inlet to the outlet of the machine. The casing is divided into compartments by fixed or

rotating partitions provided with openings for the passage of the materials from one compartment to the next.—W. H. C.

Tube mills; Liner for —. F. E. Johnson, Salt Lake City, Utah, Assignor to American Manganes Steel Co., Augusta, Me. U. S. Pat. 1,243,742, Oct. 22, 1917. Date of appl., May 26, 1916.

A TUBE mill with central cylindrical portion and conical ends is provided with a liner consisting of a number of lining plates with bevelled edges. The plates are locked and held in position by removable wedge-shaped holding bars, those in the cylindrical part of the mill extending beyond the outer working surface of the lining and those in the conical portion diminishing in height above the outer surface of the plates towards the ends remote from the cylindrical portion of the mill. These ends of the bars lie flush with the face of the lining plate.—J. H. P.

[*Tunnel*] *furnaces*. C. M. Stein et Cie., Paris. Eng. Pat. 106,606, Nov. 24, 1916. (Appl. No. 16,895 of 1916.) Under Int. Conv., May 25, 1916.

IN a tunnel furnace of the kind in which the material passes in succession through a preliminary heating passage, a central maximum temperature passage, and a progressive cooling passage, the two passages of lower temperature are heated by independent supplies of fuel and air without the use of regenerators. The gas and air for heating the central passage, or the air only, pass through continuous or alternate regenerators to the central combustion space of the furnace.—W. F. F.

Furnaces and the like; Method of and means for lining or re-lining —. I. Hall, Birmingham. Eng. Pat. 111,007, Jan. 31, 1917. (Appl. No. 1558 of 1917.)

IN the method of lining, re-lining, or repairing furnaces and the like by the insertion of a core around which the refractory material is placed and subsequently withdrawing the core, the lower part of the furnace is enlarged to form a combustion chamber and a corresponding supplementary annular core is also used. The combustion chamber may be in the form of a frustum of a cone with or without a lower cylindrical portion. An additional core may also be provided to form a tangential inlet to the combustion chamber. The annular core may be made in sections to facilitate withdrawal.—W. F. F.

Extracting dust from gases and vapours, applicable also for collecting particles of flour, cement, and other substances; [Electrical] apparatus for —. G. A. Gallot, Paris, and P. M. N. Poussin, Pantin, France. Eng. Pat. 110,774, Sept. 28, 1916. (Appl. No. 13,826 of 1916.)

To prevent sparking and so allow a current of greater intensity to be used in electrical dust separators, the central electrode, if a wire, is provided at the inlet and outlet with sleeves of glass, mica, or other dielectric medium, mounted concentrically upon the wire and projecting some distance into the surrounding perforated cylindrical electrode. If the central electrode is a wire cylinder then both ends are tapered or rounded off to increase the spark gap.—W. H. C.

Expressing liquid from materials [sewage sludge and fish refuse] containing the same; Process for —. J. W. Hinchley, London, and G. Gorton, Bexhill-on-Sea. Eng. Pat. 110,601, Oct. 26, 1916. (Appl. No. 15,262 of 1916.) Addition to Eng. Pat. 3998, Mar. 13, 1915 (this J., 1916, 1254).

THE process for expressing liquids described in

the principal patent is applied to sewage sludge and fish refuse. The preliminary pressing is carried out at a pressure of about $\frac{1}{2}$ ton per sq. in., the steam admitted at about 200 lb. per sq. in. and at a temperature about 380°F. (193°C.), and the final pressing carried out at about 2 tons per sq. in.—W. F. F.

Desiccating fluids; Means and methods of —. C. E. Rogers, Detroit, Mich. U.S. Pat. 1,243,878, Oct. 22, 1917. Date of appl., Sept. 17, 1914.

THE fluid is sprayed into and falls through a current of heated air in a chamber, and the moist air passes through a screened aperture in the chamber wall near the bottom.—J. H. P.

Dryer. [Process of drying.] C. A. Wendell, Joliet, Ill. U.S. Pat. 1,244,007, Oct. 23, 1917. Date of appl., June 12, 1915.

GRANULAR or lumpy material is fed by a flowing stream to successive sections of an annular mass of the material which is rotated to expel water, and the material is expelled in successive sections by centrifugal force. The discharged section is just in advance of the section which is being fed.—J. H. P.

Liquid and gas contact apparatus. A. M. Webb, Charlotte, N.C. U.S.A. Eng. Pat. 110,724, June 30, 1917. (Appl. No. 9452 of 1917.)

IN an apparatus for intimately mixing vapours or gases with each other or with liquids, e.g., in the manufacture of sulphuric acid, a number of short tubular mixing devices are packed in a tower. Each mixing device comprises a tube spirally corrugated and provided internally and externally with helices corrugated longitudinally and of opposite pitch. The whole is enclosed in an outer tube. The gases enter at the bottom of the tower, passing upwards through the mixing devices, which are arranged in staggered relation, and the absorbing liquid is sprayed into the top of the tower.—W. F. F.

Vacuum pumps and compressors used for the pneumatic transport of grain and granular materials. C. Bentham, and Henry Simon, Ltd., Manchester. Eng. Pat. 110,983, Dec. 16, 1916. (Appl. No. 18,090 of 1916.)

PISTON rings for vacuum pumps or air compressors, for use in pneumatic apparatus for the transport of grain or granular materials, are made wholly or partly of anti-friction metal or alloy so that liquid lubricant is unnecessary. The rings are provided with recesses filled with graphite or other dry lubricant.—W. F. F.

Washing sand; Machines for —. J. Southall, Worcester. Eng. Pat. 111,061, June 26, 1917. (Appl. No. 9147 of 1917.)

A SAND washer comprises a tank the bottom of which is composed of parallel cylindrical sections each provided with a paddle stirring device. All the bearings are above the surface of water in the tank. Sand to be washed is introduced at one end, passes through the compartments of the tank in succession, and is withdrawn from the last compartment by rotating scoops from which it is discharged at the inner ends into the smaller end of a concentric horizontal cone. Suitable drain holes for water are also provided in the scoops. The sand finally passes out from the larger end of the cone, and washing water passes through the tank in the reverse direction to that of the sand.—W. F. F.

Thermostats. H. H. Grundy, London, Eng. Pat. 110,938, Nov. 7, 1916. (Appl. No. 15,962 of 1916.) Addition to Eng. Pat. 5311, Mar. 2, 1912.

Valves for controlling, reversing, and by-passing the flow of gas through scrubbers, purifiers, condensers, and the like. R. Dempster and Sons, Ltd., and J. E. Horsfall, Elland, Eng. Pat. 111,036, Mar. 28, 1917. (Appl. No. 4177 of 1917.)

Adhesive, plastic, or semi-fluid substances; Process and apparatus for extracting fluid from—. A. N. Hood, Newton, Mass., U.S.A. Eng. Pat. 110,737, Sept. 11, 1917. (Appl. No. 13,035 of 1917.)

SEE U.S. Pat. 1,240,816 and 1,212,518 of 1917; this J., 1917, 1191, 1227.

Gas burners for metallurgical and other furnaces. Eng. Pat. 110,960. See IIa.

Method of and apparatus for draining and concentrating coal and other slimes and materials of a like nature. Eng. Pat. 110,994. See IIa.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; The nitrogen content of oxidised—. P. Mahler, Comptes rend., 1917, 165, 634—636.

THE percentage of nitrogen in coal varies from 0.7 to 2.5%. The author confirms the view of H. Fayol that the main effect of the action of air on coal is to oxidise and dehydrogenate the organic matter, with formation of humic matters. Analyses were made of eight samples of Decazeville coals which heat up readily under the action of oxygen and ignite spontaneously. The specimens were taken at the outcrop at Combes in the vicinity of an interstratification of sandstone, where coals with various degrees of oxidation are formed, from those of 8000 cal. and 36% of volatile matter to 5200 cal. and 52% of volatile matter. Calculated on the pure coal substance the carbon ranged from 81.4% to 64.9%, the hydrogen from 5.3% to 3.0%, the nitrogen from 1.7% to 2.5%, the oxygen and sulphur (by difference) from 11.6% to 29.6%. The percentage of humic matter in the raw coal increased from 0.5 to 70%. Allowing for ash and water, the proportion of nitrogen is very little altered except in the coals greatly decomposed and almost completely transformed to humic matter, in which case the nitrogen content appears to increase, approaching the figure met with in ordinary vegetable humic matter.—J. E. C.

Ignition of gaseous mixtures; Temperature of—. J. W. McDavid. Chem. Soc. Trans., 1917, 111, 1003—1015.

MEASUREMENTS of the temperature of ignition of a number of gaseous mixtures were made by igniting a small volume of the mixture contained in a soap bubble by means of a heated body, the temperature of which could be noted as ignition took place. Several forms of ignition apparatus were tested; that finally adopted consisted of a platinum wire wound round mica, and connected with storage batteries, a variable resistance, and an ammeter. Ammeter readings for four known temperatures were taken by melting small quantities of pure salts of known m.p.s. on the wire. A graph was constructed from these readings whereby the temperature could be determined from the amperage. This was found more reliable than using a thermo-couple. Results obtained for the ignition temperature of various mixtures by this method were as follows:—coal gas—air, 878° C.; ethylene—air, 1000° C.; hydrogen—air, 747° C.;

carbon monoxide—air, 931° C.; petrol—air, 995° C.; benzene—air, 1062° C.; ether—air, 1033° C.

—L. A. C.

Flame; "Uniform movement" during the propagation of—. W. Mason and R. V. Wheeler. Chem. Soc. Trans., 1917, 111, 1044—1057.

THE authors discuss deductions of Mallard and Le Chatelier (Ann. des. Mines, 1883, [viii.], 4, 274) and others concerning the speed of flame during "uniform movement," especially that one according to which, in mixtures having the same conductivity for heat, the speed of the flame during the uniform movement should be directly proportional to $T-t$, and inversely proportional to $l-\theta$ (T , t , and θ are respectively the temperatures of the gases during combustion, during ignition, and before ignition.) It is shown experimentally that this relation holds very closely for mixtures of methane and oxygen in which complete combustion takes place; when, however, combustion is incomplete, the above ratio is generally higher than the velocity requires. In measuring the velocities of flame, the tubes employed should be between 5 and 10 cm. in diameter. Under 5 cm., cooling by the walls of the tube reduces the velocity to a considerable extent; above 10 cm., convection currents cause vibratory movements which increase the true velocity. Ignition should be effected at or within 3 or 4 cm. of the open end of the tube; if it takes place within the tube, flame travels in both directions from the point of ignition, resulting in vibratory motion, and very variable speed records are obtained.—L. A. C.

Sulphur; Use of the water from the Lewis-Thompson calorimeter for the determination of— in fuels. P. Falcicola. Annali Chim. Appl., 1917, 8, 77—82.

IN calorimetric determinations of lignite and other fuels in the Lewis-Thompson calorimeter, sulphur is completely oxidised to sulphuric acid. It may be readily determined by evaporating 500 c.c. of water from the calorimeter to a small bulk, acidifying the liquid with hydrochloric acid, and precipitating the sulphur as barium sulphate. The results thus obtained with lignites containing from 1 to 4% of sulphur were about 0.1% higher than those obtained by Eschka's method.—C.A.M.

Gas furnaces; Design and manipulation of—. A. Forshaw. Manchester and District Junior Gas Association, Nov. 2, 1917. Gas J., 1917, 140, 327—331, 372—375.

THE thermal efficiency of coke-fired crucible furnaces is very low, being only 5% for the best pit furnaces and 15% for the best tilting furnaces. The fuel costs are, however, also so low that it is only by studying all the factors that the cost of melting metals by coke and by gas can be compared. Great care should be taken of the linings of gas furnaces, to minimise wear or corrosion by the slagging of spilt metal. Apart from the interference of molten slag with the burners, destruction of the lining leads to enlargement of the combustion space round the crucible and consequent increased fuel consumption. Accumulation of slag should be prevented. Using gas furnaces, melts can be put through more quickly, so that the output of a given number of furnaces can be increased from 50% upwards. Hints are given on the care of crucibles, preliminary annealing, drying, and attention to the action of fluxes. The labour costs of melting by gas are less than by coke firing, no fuel and ash having to be handled. The life of the crucibles is also usually longer. In works practice the gas consumption is determined by a number of factors, which must be taken into consideration in estimating the practical efficiency of melting with gas. The author does

not favour the use of high pressure gas as against air blast. Increased efficiency can be attained by preheating the metal by means of the hot products of combustion, the saving of gas being as much as one-third. On the other hand, recuperation in small gas melting furnaces has not yet been found of any appreciable benefit. Preheating, however, may prove injurious by oxidation of the metal, involving changes of composition and properties. Gas-heated annealing ovens may be of the natural draught or air blast types, or of an intermediate type using air driven by a low-pressure fan at 6 in. water pressure. The ovens are generally heated internally to diminish gas consumption, and it is desirable to provide means for making the atmosphere oxidising or reducing to suit the materials under treatment. Hardening and tempering of steels are discussed and the advantages of salt baths with controlled temperatures are emphasised where precision is important. The manipulation of gas furnaces is facilitated by uniformity of composition, calorific value, and pressure of the gaseous fuel. It is often a great advantage to pass the supply of town gas through a governor before use.—H. J. H.

Carbonising coal; Most economical method of — for supplying light, heat, and power by the gas industry and the maximum supply of munitions of war. J. West. Southern Assoc. of Gas Eng. and Managers, Nov. 8, 1917. Gas J., 1917, 140, 314—320.

THE paper gives results of experiments in the carbonisation of coal for various purposes. Tests made on Kent coal (Beresford seam) were disappointing owing to the low percentage of volatile matter and high ash content. Results at high temperature in retorts of the Glover-West type showed a loss of 5½d., and at low temperature of 11s. per ton of coal carbonised. After a few preliminary trials in horizontal retorts, a coal was found of suitable quality. Thus Haigh Moor coal gave in small horizontal retorts 11,800 cb. ft. of gas of 457 B.Th.U. net, 14.57 galls. of tar, 21.6 lb. of ammonium sulphate, and 70% of good quality coke. 1000 tons of this coal tested in Glover-West vertical retorts at St. Helens gave the following results at high and medium temperatures respectively. Temperature inside retorts, 1362° and 1160° C.; gas per ton, corrected, 14,050 and 13,387 cb. ft.; gross calorific value, 556 and 567.7 B.Th.U.; tar per ton of coal, 16.06 and 16.5 galls.; ammonium sulphate per ton of coal, 23.6 and 26 lb. The profit at high temperature is given as £1 1s. 2d. per ton of coal carbonised, and at medium temperature as 18s. 4d. per ton. When the gas, stripped of benzol and toluol, was re-passed through the charge, the make of gas was slightly increased, the volatile matter in the coke was reduced to zero, and the make of tar was increased by some 2 to 3 galls. per ton. The calorific value of the gas, after being stripped of its illuminants, was never below 450 B.Th.U. The advantages of high temperature carbonisation are summarised as follows:—Less ground area is required for buildings, less carbonising plant, capital, and labour, higher yield of gas, better and harder coke, tar and liquor not reduced in quantity and of better quality for war work. The author gives the following results of continuous steaming in vertical retorts built up in segments of special silica material. Temperature outside retorts, 1395° C.; gas per ton, corrected, 15,487 cb. ft.; gross calorific value, 506 B.Th.U.; tar made, 17.7 galls.; ammoniacal liquor (10 oz.), 32.6 galls. With a temperature of 1415° C. and using steam at 45 lb. pressure through a ½ in. nozzle, the gas per ton reached 17,460 cb. ft. of 494 B.Th.U. gross calorific value, with a satisfactory yield of tar of good quality. The retorts do not appear to have suffered unduly through this admission of steam,

as the steam passes through the coke chambers, and arrives at the retort proper in a dry, superheated condition. By steaming the output may be increased by 20 to 25% and the calorific power may at the same time be maintained above 500 B.Th.U., the author recommending a steam pressure of 40 lb. At the Uddingston Gas Works, a yield of 19,450 cb. ft. of gas has been attained with an output of 23.25 gallons of tar and crude benzol and 52.34 lb. of ammonium sulphate. The following advantages of steaming (with Lanarkshire coal) are claimed:—Greater capacity of plant and reduction in labour costs; increase of gas made by 40 to 50%; lower air:gas ratio of gas with increase of flame temperature; low percentage of non-combustible gases; increase of 60 to 70% in tar products, and of 50 to 60% in ammonia products. At Lurgan a yield of 16,046 cb. ft. of gas per ton of an average calorific value of 500 B.Th.U. was obtained. The retorts at Uddingston and Lurgan do not appear to have sustained any damage by steaming, some of the retorts having been in operation over 2½ years. The author considers gas of 450 to 500 B.Th.U. to be the most suitable and economical that can be made for all purposes. The larger amount of shale now delivered with the coal, as compared with pre-war times, is calculated to be equivalent to a loss of 1206 cb. ft. of gas, 1.4 galls. of tar, and 2.8 galls. of 10 oz. liquor per ton of coal carbonised. The following suggestions are submitted to meet the demand of the Ministry of Munitions for tar for war purposes:—A General Act should be passed for the universal application of the calorific power standard, stripped gas should be used for heating retorts in cases where coke is in great demand, and it should be required that shale is picked out at the colliery before delivery. Further, gas undertakings should see that only gas of good quality is supplied to the public.—J. E. C.

Gas from straw. R. D. McLaurin. Gas J., 1917, 140, 326.

THE author discusses the possibilities of straw as a source of gas, more particularly in Canada, where great quantities of straw are wasted annually. Straw is compressed in a baling machine to a density of 25 lb. per cub. ft. and inserted in a retort of highly refined steel, 7 ft. 6 ins. long, 24 ins. wide, and 6½ ins. deep, enclosed in a casing with fire-box below. The total cost, including a scrubber and gasholder, in Canada, is about £105. The temperature reaches a maximum between 500° and 600° C., and all the gas is removed in about 30 to 45 mins. Each ton of straw gives 11,000 to 12,000 cb. ft. of gas, 6 to 8 galls. of tar and ammoniacal liquor, and 600 lb. of carbon residue (lampblack). About 30% of the gas is used to assist the carbonisation, leaving a surplus of 7000 cb. ft. of a calorific value of 400 B.Th.U. per cub. ft., equivalent to 25 galls. of petrol. The gas consists of methane, hydrogen, and carbon monoxide and may be used in the same manner as coal gas.—J. E. C.

Toluol; Recovery of — from gas-works. Advance proof of Report of Sub-Committee of American Gas Institute on Coal-tar By-products. Gas J., 1917, 140, 366—367.

THE report deals with the possibilities in the way of toluol recovery in gas-works in the United States, where, owing to the extensive manufacture of carburetted water-gas, the conditions differ considerably from those met with in British practice. It is estimated that about 3,000,000 gallons will be recovered in gas-works in 1918, whereas about 9,000,000 gallons could be obtained by including all works capable of producing more than 10,000 gallons per annum. The yield of pure toluol is reckoned at 1.6% of the gas oil used in

carburettling. A plant for stripping the benzolised oil by steam is described and the use of a minimum steam pressure of 100 lb. is recommended. It is estimated that steam equivalent to 1.3 H.P. per gallon of light oil distilled will be required. Tanks for the settling of naphthalene from the wash oil are to be used. The estimated scrubbing capacity is 30 cb. ft. per 1000 cb. ft. of gas washed. It is calculated that the loss of illuminating power due to stripping will be about 34% of the candle power communicated to the water-gas by the original gas oil, provided that the crude benzol fraction be returned to the gas. It is usual to carburet with 3.8 gallons of gas oil per 1000 cb. ft. of gas, and as the loss of illuminating power is 1.95 candles per gallon, the fall in illuminating power will be about 7.4 candles. The average loss in heating value will be 27 B.Th.U. or about 5% of the calorific value. As wash oil, a so-called "straw oil," apparently of mineral origin, is recommended, and also creosote oils such as are available and in general use in this country.—H. J. H.

Gasolene; Synthetic — by electrochemical means. L. B. Cherry. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 20 pages. (See also U.S. Pat. 1,229,886; this J., 1917, 863.)

The author has found that when mixtures of heavy hydrocarbon vapours and methane are passed through heated tubes, and there subjected to the electrical discharge of a high-tension, high-frequency oscillating current, intermediate products are obtained. Working on kerosene (sp. gr. 0.81) and natural gas, at a pressure of 75 lb. per sq. in., with 2-ft. treatment chambers and a current at about 40,000 volts, 56% of the kerosene was converted into distillates boiling between 45° and 160° C., with an average sp. gr. of 0.751. By increasing the voltage and frequency of the current, and using 10-ft. treatment chambers, a 78% conversion was obtained with kerosene, and it is expected that by increasing the length of the treatment chambers to 34 ft. an efficiency approaching 100% conversion will be obtained. The total cost of electrical energy for heating the chambers and supplying the conversion current is estimated at 0.4 cent per gallon, based on a cost of supply of 0.6 cent per kilowatt-hour. A detailed description is given of the specially designed high-frequency installation employed.

Coal and other slimes and materials of like nature; Method of and apparatus for draining and concentrating —. S. Hunter, and Simon-Carves, Ltd., Manchester. Eng. Pat. 110,994, Jan. 8, 1917. (Appl. No. 333 of 1917.) Addition to Eng. Pat. 22,189 of 1913 (this J., 1914, 410).

WASHED material from the primary sieve, in which the slimes are separated, is conducted to the shaker sieve, and the concentrated slimes returned to the washed material just prior to delivery to the primary sieve, or, by an intermediate sieve, to the washed material passing over the primary or the shaker sieve.—J. E. C.

Coking-furnace. H. G. Stone, Chicago, Ill. U.S. Pat. 1,243,776, Oct. 23, 1917. Date of appl., June 23, 1915.

COAL is passed downwards through a vertical chamber which is heated by a current of gas at a high temperature admitted near the base. The

chamber is provided with a number of perforated dampers, and an outlet for combustion products is arranged in the space above each damper; an outlet for distillation products is also provided in the upper part of the chamber. Means are provided for preventing the admission of air when charging or discharging the furnace.—A. B. S.

Coke ovens; Controllable and removable gas and air nozzles for — and analogous devices. D. Bagley, Westminster. Eng. Pat. 110,053, May 31, 1917. (Appl. No. 7800 of 1917.)

IN a coke oven or analogous device heated by vertical flues, the supply of gas or of air for combustion is controlled by an adjustable nozzle held in position by wings resting normally on the ledges attached to the sides of the flue. The cap of the nozzle is of screw form, capable of being rotated through an angle of 360°, thus regulating the amount of gas passing through side apertures in the nozzle. A protecting nozzle may be fitted in the flue above the gas nozzle to protect the latter from the effects of radiation from the flues, and both nozzles may be removed or controlled from passages underneath the oven structure.

—J. E. C.

Gas producer. H. A. Driffield, Chicago, Ill. U.S. Pat. 1,243,822, Oct. 23, 1917. Date of appl., Jan. 12, 1915.

The producer consists of a shell to contain the fuel, a bosh adjacent to the lower end of the shell, and a table attached to and below the bosh. An undulating motion is imparted to the table and bosh by suitable mechanism.—J. H. P.

Gas burners for metallurgical and other furnaces. H. J. Yates, Birmingham, S. N. and E. R. Brayshaw, Manchester. Eng. Pat. 110,960, Nov. 21, 1916. (Appl. No. 16,662 of 1916.)

A METALLURGICAL furnace is constructed with a separate combustion chamber of L-shape formed in or inserted in the wall of the furnace for each burner. Gas, with an insufficient supply of air, is admitted into the side of the vertical portion of the combustion chamber, whilst an air nozzle delivers air at the upper end of this portion. This air sweeps across the outlet of the gas nozzle and carries the mixed gas and air to the horizontal portion of the burner for combustion. The horizontal portion has flared or inclined sides to allow the flame to spread laterally as it enters the furnace. The burner is specially designed to work with gas at normal (main) pressure and with air of only a few inches head of water; it may, however, be used with gas under pressure.—J. E. C.

Waste oils from motor garages; Utilisation of —. G. E. Heyl, London. Eng. Pat. 110,631, Nov. 10, 1916. (Appl. No. 16,168 of 1916.)

WASTE oil, collected from garages, is filtered and fractionally distilled in presence of 2½ to 10% of caustic alkali. Finely divided carbon, produced by the cracking of the lubricating oils, is thus retained in the still, giving a clear oil.—L. A. C.

Oil-treating device. F. G. White, Los Angeles, and W. J. Barnhart, Maricopa, Cal. U.S. Pat. 1,242,292, Oct. 9, 1917. Date of appl., Oct. 19, 1915.

OIL is heated by forcing it under pressure through a coil of pipes arranged in a furnace, a predetermined pressure being maintained by means of a pressure valve placed at the discharge end of the pipe coil. The heated oil is discharged into a heating pan where it is further heated, and where the pressure on the oil is relieved. The heating pan consists of an elongated closed receptacle divided into a series of compartments by longitudinal vertical baffles, which extend alternately

from the top and bottom. The oil is thus caused to follow a vertically undulating route in its passage from end to end of the pan. The baffles attached to the bottom extend about half way to the top, and those attached to the top extend progressively nearer to the bottom towards the outlet end. A pipe is provided at the top of each compartment to carry away the vapours given off by the oil in its passage through the heating pan.—T. St.

Motor-spirit; Process for the production of — from heavy hydrocarbons. W. A. Hall, New York. U.S. Pat. 1,242,795, Oct. 9, 1917. Date of appl., Mar. 12, 1914.

HYDROCARBON oil is cracked at a pressure materially above atmospheric and at a temperature not below about 500° C., whereby a mixture of gases and vapours rich in compounds of the ethylene series is produced. The portions having boiling points of about 200° C. and above are separated, leaving a mixture of gases and vapours at a temperature of over 100° C. This mixture is then cooled under a pressure materially above atmospheric to condense a motor fuel.—T. St.

Motor fuel; Producing —. W. A. Hall, New York. U.S. Pat. 1,242,796, Oct. 9, 1917. Date of appl., Apr. 4, 1914.

HYDROCARBON oils are cracked at about 600° to 650° C. under a pressure of about 70 lb. per sq. in. The pressure is then reduced and the temperature lowered to about 200° C. to separate the more readily condensable products. The remaining gases and vapours are afterwards again subjected to a pressure of at least about 70 lb. per sq. in. and still further cooled.—T. St.

Paraffin oil; Process for solidifying —. J. Minuto and J. Porte, London. Eng. Pat. 110,926. (Appl. Nos. 15,797, Nov. 4, 1916, and 6396, May 4, 1917.)

In order to render paraffin oil more or less solid or consistent, soap powder with or without camphor, sawdust, or other ingredients is dissolved in the heated paraffin, with stirring, and the liquid mixture poured into moulds or tins.

Electron-discharge apparatus and method of preparation. Electron-discharge apparatus and method of operating the same. I. Langmuir, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pats. (A) 1,244,216 and (B) 1,244,217, Oct. 23, 1917. Dates of appl., (A) July 15, 1914, renewed June 25, 1917; (B) Oct. 28, 1915.

(A) THE cathode for an electron-discharge apparatus is composed of tungsten, and is provided with a surface film of thorium material, volatile at a temperature of about 2300° absolute. The surface film is removable by positive ionisation, and has an electron emissivity, independently of and in

the absence of positive ionisation, which is many times greater than that of pure tungsten at the same temperature. (B) The electrode, as described above, is enclosed in an envelope evacuated to a pressure so low that positive ionisation is substantially absent, and a small quantity of a volatile metal, such as potassium, is contained within the envelope, the vapour of the metal preventing the oxidation of the thorium at an elevated temperature.—B. N.

Electrode; Arc-lamp —. W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pats. (A) 1,244,358 and (B) 1,244,359, Oct. 23, 1917. Dates of appl., (A) Feb. 28, 1916, and (B) Nov. 6, 1916.

(A) AN electrode is composed of sodium uranium fluoride, and a conducting body of carbon. (B) The electrode is made by mixing rare-earth metal fluorides containing a small amount of sulphate with barium fluoride, the amount of the latter being one-half to five times the weight of combined sulphuric anhydride, and heating to form barium sulphate. Calcium fluoride and carbon are also contained in the electrode.—B. N.

Candles. Eng. Pat. 110579. See XII.

III.—TAR AND TAR PRODUCTS.

Anthracene, anthraquinone, parabromobenzene, phenanthrene, and iodine; Solubilities of — in various solvents. J. H. Hildebrand, E. T. Ellefson, and C. W. Beebe. J. Amer. Chem. Soc., 1917, 39, 2301—2302.

To determine the solubilities of anthracene, etc., in various solvents, quantities of the solid were agitated with the solvent in a thermostat at 25° C. until equilibrium was attained. A weighed quantity of the solution was then evaporated and the residue weighed. The solutes were from a commercial source, and, in most cases, not purified; the solvents were dried and distilled. The materials were chosen with a view to obtain solubility data for solutions relatively free from complications due to association and ionisation. Average results are given in the following table:—

Solvent.	Solubilities at 25° C. (In grms. per 100 grms. of solvent.)				
	Anthracene.	Anthraquinone.	p-Bromobenzene.	Phenanthrene.	Iodine.
Alcohol	0.328	0.437	10.35	4.91	—
Benzene	1.86	—	83.8	59.5	—
Carbon bisulphide	2.58	—	90.0	80.3	—
Carbon tetrachloride	0.732	—	36.6	26.3	—

Nitro- and nitroso-compounds; Reduction of — with platinum and hydrogen. G. Cusmano. Atti. R. Accad. Lincei. 1917, [v.], 26, ii., 87—91. J. Chem. Soc., 1917, 112, i., 641

AROMATIC mononitro-compounds (*p*-nitrophenol, *p*-nitroanisol, and *p*-nitrotoluene) are reduced to amines by hydrogen and platinum-black at the ordinary temperature, no matter what quantity of hydrogen is present. The aromatic nitroso-compounds behave in the same way (*p*-nitrosophenol, *p*-nitrosothymol, *p*-nitrosodimethylaniline, and the nitrosonaphthols). In the same

conditions, terpene nitroso-compounds are reduced quantitatively to the corresponding hydroxylamines; thus, 8-nitrosomenthone is converted into 8-hydroxylaminomenthone.

Quinol; Sulphonation of —. J. Pinnow. Z. Elektrochem., 1917, 23, 243—249. J. Chem. Soc., 1917, 112, ii., 528. (Compare this J., 1915, 1083.)

A CONTINUATION of the previous work; the kinetics of the sulphonation of quinol have been studied at 100°, 80°, 60°, and 50° C. by a slightly modified method, using sulphuric acid from 7.82*M* to 13.39*M*. It is shown that if quinol is added to sulphuric acid in such quantities (1—2%) that the total volume is practically unchanged, the logarithm of the velocity of sulphonation increases proportionally to the concentration of the acid. For unit increase in the molarity of the acid, the increase in the logarithm is 0.643 at 60°, 0.612 at 80°, and 0.696 at 100° C. The logarithm of the velocity for 7*M* H₂SO₄ is 4.500 at 60°, 5.655 at 80°, and 6.637 at 100° C. The equilibrium between quinol, quinolmonosulphonic acid, and aqueous sulphuric acid moves toward the sulphonated acid with decreasing temperature. The temperature-coefficient of the formation and hydrolysis of quinolmonosulphonic acid increases with decreasing concentration of sulphuric acid. The hydrolysis depends chiefly on the monohydrate of sulphuric acid, as was previously shown to be the case in the formation of the monosulphonic acid.

Phenols; Influence of the solvent on the reaction between polyhydric — and alkali bicarbonates. F. von Hemmelmayr. Monatsh. Chem., 1917, 38, 77—89. J. Chem. Soc., 1917, 112, i., 645—646.

THE reaction between potassium bicarbonate and polyhydric phenols under different conditions has been studied. Using anhydrous substances and working at atmospheric pressure, resorcinol, at 120° C., yields 2,4- and 2,6-dihydroxybenzoic acids, catechol and quinol produce no carboxylic acids, and pyrogallol yields 2,3,4-trihydroxybenzoic acid. When the anhydrous substances are heated in closed tubes, catechol at 200° C. yields catecholdicarboxylic acid, resorcinol forms α -resodicarboxylic acid, and 3,5-dihydroxybenzoic acid yields β -resodicarboxylic acid; quinol at 260—270° C. gives a high yield of a dicarboxylic acid, which crystallises in needles with H₂O; pyrogallol at 200° C. forms gallo-carboxylic acid, m.pt. 281° C., the yield being almost the theoretical one; orcinol gives *p*-orsellinic acid. 1,5-Dihydroxynaphthalene at 230° C. yields a dicarboxylic acid, which decomposes at 290° and then melts at 300° C.; the acid and its alkali salts dye wool yellow, and the shade is converted into a very good brown by treatment with chromic acid or chromates. 1,6-Dihydroxynaphthalene reacts with a mixture of potassium bicarbonate and carbonate to form a monocarboxylic acid, in stellate groups of yellow prisms, m.pt. 200° C. By heating with potassium bicarbonate in presence of dry aniline or diphenylamine at atmospheric pressure, resorcinol yield β -resorcylic acid and also α -resodicarboxylic acid, especially with diphenylamine, although this acid loses carbon dioxide most readily if heated alone with the bases. Catechol and quinol do not react, and pyrogallol forms only a monocarboxylic acid. In presence of boiling anhydrous ethyl alcohol, although it boils at a higher temperature than diphenylamine, the yield of α -resodicarboxylic acid from resorcinol is not so great as in the above case.

Recovery of toluol from gas-works. See II A.

PATENTS.

Waste hydrocarbonaceous residues; Obtaining valuable products from — produced in the rectification of crude benzol and homologous hydrocarbons. J. T. Sheard. Sheffield. Eng. Pat. 110,636, Nov. 18, 1916. (Appl. No. 16,556 of 1916.)

THE waste oily residue produced when crude benzol or its homologues are rectified by steam distillation as described in Eng. Pat. 104,999 (this J., 1917, 565), is distilled until the temperature of the vapours at the still-head is about 285° C.; the hot residue is then run off, and after partial cooling is either filtered or the sediment allowed to settle. The oil obtained, of sp.gr. 1.060 or thereabouts, is suitable for use as a lubricant for steam engines and other machinery. The condensed product consists chiefly of water and small quantities of various hydrocarbons.—L. A. C.

Phenolic bodies from wood-tar oils; Process of producing —. L. F. Hawley. Madison, Wis. Re-issue 14,388, Oct. 30, 1917, of U.S. Pat. 1,199,271, Sep. 26, 1916. Date of appl. Aug. 13, 1917.

SEE this J., 1916, 1149.

IV.—COLOURING MATTERS AND DYES.

Rhodanines; Substituted — and some of their aldehyde condensation products. R. Andreasch. Monatsh. Chem., 1917, 38, 121—139. J. Chem. Soc., 1917, 112, i., 663—664.

3-PHENYLRHODANINE and *p*-aminobenzaldehyde condense in warm acetic acid to form 3-phenyl-5-*p*-aminobenzylidenetherhodanine,

which crystallises in bichromate-coloured, filamentous needles, m. pt. 227—228° C., and dyes skin, wool, or silk yellow. Protocatechualdehyde and 3-phenylrhodanine form 3-phenyl-5-*mp*-di-hydroxybenzylidenetherhodanine, bright yellow needles, m.pt. above 260° C. This behaves like an indicator, for aqueous suspensions give with alkali hydroxides very deep violet solutions, which become yellow again on neutralisation. The compound is in many other respects like alizarin; it is a vat dye, but does not give nice shades. The corresponding 5-*op*-dihydroxybenzylidene compound is an orange-yellow, crystalline powder, m. pt. about 350° C., which gives carmine-red solutions with traces of alkali hydroxide.

Phenylrhodanine and the related ring systems also condense with isatin. 3-Phenyl-5- ψ -indoxylidenetherhodanine,

crystallises as a purple-red, shimmering scale, m. pt. 260° C. "Isothiohydantoin-2-indolindigo" [2-imino-4-keto-5- ψ -indoxylidenethiazolidine],

is a brownish-red powder, m. pt. above 360° C. 2,4-Diketo-5- ψ -indoxylidenethiazolidine is an orange-yellow powder, m.pt. above 370° C. "5- ψ -Indoxylrhodanine" is identical with Felix and Friedländer's "5-thiazolthiol-2-indoleindigo" (this J., 1910, 410).

Influence of the solvent on the reaction between polyhydric phenols and alkali bicarbonates. Von Hemmelmayr. See III.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.**PATENTS.**

Paper-making machines, pulp-drying machines, pulp vats; Suction roll arrangements for — and for drying cloth or like porous and absorbent material. G. Hellström, London, Eng. Pat. 105,556, Apr. 5, 1917. (Appl. No. 4947 of 1917.)

THE perforated suction roll is revolved in air-tight contact with an external stationary suction box covering the bottom segment of the roll. The web of paper or fabric travels in contact with the major portion of the circumference of the roll not covered by the suction box. The segments between the lips of the external suction box and the points where the web of paper passes on to and off the suction roll are covered by stationary chambers inside the roll in communication with the outside atmosphere and isolated from the suction of the suction box by air-tight packing bars. The suction produced in the external suction box operates inside the revolving roll on the portions covered by the web of paper and draws the water through into the interior of the roll, then out through the lower portion into the external suction box, thus washing the perforations of the roll-shell clear of deposits of fibre.—J. F. B.

Acetylcellulose; Process for producing flowable compounds of —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Company, New York. U.S. Pats. (A) 1,244,107 and (B) 1,244,108, Oct. 23, 1917. Date of appl., (A) Nov. 6, 1911. Renewed Mar. 19, 1917; (B) Mar. 19, 1917.

(A) 100 PARTS of acetone-soluble acetylcellulose is incorporated with 20 to 50 parts of an arylsulphamide, 40 to 100 parts of methyl or ethyl alcohol, and 10 to 40 parts of a liquid adapted to produce a solution which will flow in the cold, e.g., a mixture of 70 parts of alcohol and 30 parts of chloroform by volume. (B) The arylsulphamide is replaced by an alkylarylacetamide. A triarylphosphoric ester may also be added.—F. Sp.

Acetylcellulose plastics and solvents thereof; Process of making —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pats. (A) 1,244,347 and (B) 1,244,348, Oct. 23, 1917. Date of appl., (A) Nov. 6, 1911. Renewed Mar. 19, 1917; (B) Mar. 19, 1917.

(A) 100 PARTS of acetone-soluble acetylcellulose is incorporated with 20 to 50 parts of an arylsulphamide, e.g., ethyl-p-toluenesulphamide, and 40 to 100 parts of methyl or ethyl alcohol. (B) The arylsulphamide is replaced by an alkylacetanilide having not more than two carbon atoms in the alkyl group.—F. Sp.

Acetylcellulose plastics; Process of making solvents for —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pat. 1,244,349, Oct. 23, 1917. Date of appl., Nov. 6, 1911. Renewed Mar. 20, 1917.

A COMPOUND solvent for acetone-soluble acetylcellulose is made by mixing 40 to 100 parts of ethyl or methyl alcohol and 20 to 50 parts of an arylsulphamide, e.g., a toluenesulphamide. The alcohol may contain 10 to 40% of a liquid, e.g., chloroform, adapted to produce a solution which will flow in the cold.—F. Sp.

Composition for cleansing, decorticating, and for purifying and preserving food. Eng. Pat. 110,567. See VI.

Production of oxalic acid and oxalates. Eng. Pat. 110,837. See VII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Pigment-forming enzyme of the skin; Specific —. Dopaoxydase. B. Bloch. Z. physiol. Chem., 1917, 100, 226—254. J. Chem. Soc., 1917, 112, i., 675.

WHEN a frozen section of human or other skin is treated with a 1% solution of 3,4-dihydroxyphenylalanine (termed "dopa"), oxidation and condensation occur with the formation of a dark brown or black pigment (dopamelanin) at certain definite places owing to the action of an intracellular oxidising enzyme, dopaoxydase. The oxydase is present in the protoplasm (not the nuclei) of the basal cells of the epidermis and the cells of the hair follicles, and is of a highly specific nature, exerting no action on tyrosine, quinol, homogentisic acid, pyrogallol, tryptophan, adrenaline, and other substances more or less closely related to 3,4-dihydroxyphenylalanine. A parallelism is observed between the pigmentary changes occurring in sections of skin under the action of chemically active light rays and those immersed in "dopa," and the conclusion is drawn that the natural pigment is probably formed in the living organism from 3,4-dihydroxyphenylalanine or a substance very similar to it in chemical constitution.

PATENTS.

Fulling; Process of —. A. Pinagel, Aachen, Germany. Eng. Pat. 106,608, Mar. 9, 1917. (Appl. No. 3519 of 1917.) Under Int. Conv., May 25, 1916.

FOR the fulling of woollen fabrics an aqueous alkaline solution of saponin, alone or with the addition of a little alcohol, is employed. Part of the fat or oil contained in the usual fulling agents or soaps may be replaced by saponin.—J. F. B.

Composition for cleansing, bleaching, decorticating, and for purifying and preserving food. A. Poulson, Widnes. Eng. Pat. 110,567, Oct. 9, 1916. (Appl. No. 14,315 of 1916.)

A MIXTURE of equal parts of crystalline or anhydrous sodium carbonate and sodium bicarbonate is suitable for use as a general cleansing agent for household and laundry purposes; as a cleanser of paint and varnish work, for removing the print from calico and also newspapers, as a decorticating agent for flax and other fibrous material, as a "purifier" of tainted fish, hams, etc., or as a food preservative. A scouring composition for pots and pans is obtained by mixing the powder with saponifiable oil or fat and ground pumice. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 1331 of 1870.)—A. DE W.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrogen; Action of — on sulphuric acid. F. Jones. Mem. Manchester Phil. Soc., 1917, 61, No. 3, 1—3. J. Chem. Soc., 1917, 112, ii., 530.

IN the hulk of a non-tubulated retort, the open end of the neck of which dips under water, is placed some strong sulphuric acid, the remainder of the retort being filled with pure hydrogen. When the whole is left at the ordinary temperature for a few days the water gradually rises in the neck of the retort, owing to reduction of the sulphuric acid by the hydrogen with formation of sulphur dioxide.

Alum: Residues from the manufacture of— and possible means of utilising them. P. Falcicola. *Annali Chim. Appl.*, 1917, 8, 82—87.

A LARGE proportion of the alum made in Italy is derived from leucite, a double silicate of aluminium and potassium, which occurs in the form of isolated crystals or in basaltic and other rocks. After removal of the gangue the mineral contains up to 98% of true leucite, though it is not economical to aim at a higher degree of purity than 90%. Alum is obtained by digesting leucite with dilute sulphuric acid at about 70° C., decanting the liquid from silica, and leaving it to crystallise. The mother liquors still contain about 10% of the double salt, and at least 15% of alum, which does not repay the cost of recovery. The alum from the first crystallisation contains salts of iron and silicon, together with other impurities, and a second crystallisation is necessary to obtain a pure white salt. The residue from the digestion with acid is regarded as a waste product. For every 438 kilos. of leucite 210 kilos. of silica is obtained; or in the case of 70% leucite every 100 kilos. yields about 76 kilos. of silica containing about 80% SiO_2 . A sample of the insoluble residue contained 16.6% of moisture and had sp. gr. 0.897. When dried at 100°—105° C. it had the following composition:—Total silica, 79.39; sulphuric anhydride, 6.43; ferrous oxide, 0.71; aluminium oxide, 1.83; calcium oxide, 5.90; magnesium oxide, 0.24; potassium oxide, 2.16; and sodium oxide, 4.14%. Loss on ignition, 3.35%. Only a small amount of the silica was in a combined state. By fractional sedimentation of the residue with 12 times its volume of water it could be separated into three fractions of different degrees of fineness, the first (7%) containing 65% of silica, and the third (44%), 93.7% of silica. Mixtures of 20 parts of the original residue with 100 parts of potters' clay (Vicenza clay) and 40 or 60 parts of calcium carbonate were baked at about 1000° C., and proved satisfactory for ornamental pottery. Mixed with litharge as a glaze it gave excellent results. For the manufacture of glass the best results were obtained by the use of the following formulæ:—(a) Residue (12% water), 100; Solvay soda, 41; calcium carbonate, 12. (b) Residue, 100; Solvay soda, 50; and calcium carbonate, 15 parts. Another possible use of the residue is for soaps and detergents.—C. A. M.

Chlorates: Identification of—in the presence of hypochlorites. P. Wischo. *Pharm. Post*, 1917, 50, 381. *J. Chem. Soc.*, 1917, 112, ii., 539.

THE following behaviour of the two substances towards brucine and hydrochloric acid can be used for the identification of sodium chlorate in the presence of sodium hypochlorite in Dakin's solution. When a solution of sodium hypochlorite (5 c.c.) of approximately the same concentration as Dakin's solution (about 0.5%) is treated with brucine hydrochloride or sulphate (0.05 gm.) and dilute hydrochloric acid (5 drops), a yellow coloration is developed which becomes cherry-red when the solution is boiled; the latter coloration remains unchanged when the solution is boiled with a further 10 c.c. of dilute acid. On the other hand, a similar solution of potassium chlorate is not coloured by brucine (0.05 gm.) and dilute hydrochloric acid (5 drops) in the cold; when boiled the solution becomes yellow, and, subsequently, cherry-red, but the colour is discharged when boiling is continued after a further addition of dilute hydrochloric acid (10 c.c.). This decoloration on subsequent boiling with much dilute hydrochloric acid is characteristic of the presence of chlorate; it also occurs when 5 c.c. of a solution containing

0.01 gm. of sodium hypochlorite and 0.02 gm. of potassium chlorate in water (10 c.c.) is tested as described above.

Bromides: Determination of—. E. Rupp. *Arch. Pharm.*, 1917, 255, 303—304. *J. Chem. Soc.*, 1917, 112, ii., 540.

THE bromate method of estimating the bromide in alkali bromides or their mixtures ("*bromum compositum*") is modified as follows to avoid the use of hydrogen peroxide (compare this *J.*, 1917, 924). Twenty c.c. of official dilute sulphuric acid, 50 c.c. of N/100 potassium bromate, 0.2 gm. of iodine, and 0.15 gm. of the bromide are diluted to 200 c.c., and the mixture is boiled after the addition of a little talc or powdered pumice until the volume has been diminished to 75 c.c. in not less than 40 minutes. The mixture is cooled to the ordinary temperature, 0.5—1 gm. of potassium iodide is added, and the iodine liberated by the excess of the bromate is titrated with N/10-thiosulphate after three to five minutes. When the bromide is being estimated in the presence of more than about 25% of chloride, the undiluted mixture of the sulphuric acid, potassium bromate, and iodine is concentrated to about half its volume by boiling for 15 minutes, the solution of the haloid is added, the mixture diluted to 200 c.c., and the procedure mentioned above followed. The result is 0.2—0.3 c.c. too high if the preliminary boiling is omitted.

Ferric oxide and alumina. F. H. Scheetz. *J. Phys. Chem.*, 1917, 21, 570—572.

FOLLOWING Keene's observation (this *J.*, 1917, 138) that the yellow colour in bricks is due to finely divided anhydrous ferric oxide, stabilised by alumina, the author endeavoured to produce this colour artificially by precipitating solutions of ferrous and aluminium sulphates with sodium carbonate, sodium hydroxide, and lime water respectively, and heating the precipitates to 1000° C. Sodium hydroxide and carbonate were unsatisfactory, but lime produced the required colour, providing there was not more than 8% of Fe_2O_3 in the mixed oxides.—A. B. S.

Zinc perhydrates [hydroperoxides]. F. W. Sjöström. *Z. anorg. Chem.*, 1917, 100, 237—248. *J. Chem. Soc.*, 1917, 112, ii., 533. (Compare de Forcrand, this *J.*, 1902, 505, 1041; Ebler and Krause, 1911, 892; Riesenfeld and Nottebohm, this *J.*, 1916, 536.)

WHEN a solution of zinc sulphate is added to excess of a solution of sodium hydroxide containing hydrogen peroxide, the zinc is totally precipitated as hydroperoxide. The amount of hydrogen peroxide used cannot, however, be estimated volumetrically on account of its rapid decomposition in alkaline solution. For a more thorough examination of zinc hydroperoxide the following method of preparation was used. Freshly ignited pure zinc oxide was left for several hours with the calculated quantity of 30% hydrogen peroxide solution at —10° C. A product was obtained which above 2° C. formed a pasty mass, and when dried on a porous plate at 35°—40° C. over soda-lime was obtained as a white powder. This was analysed by estimating active oxygen, zinc oxide, and water. It contained 8.04% active oxygen, and corresponded almost exactly with the composition $\text{Zn}_2\text{O}(\text{OH})\text{O}_2\text{H}$. Towards water, alcohol, or ether at the ordinary temperature it is quite stable, and is only slowly decomposed by 2N sodium hydroxide. It does not appear, however, to be a simple chemical individual, since by trituration with water it can be separated into fractions containing varying quantities of active oxygen. Another preparation, fractionated in this manner before drying, gave three similar

fractions, each containing about 12% of active oxygen and corresponding with no particular formula. Similar products were obtained by boiling zinc carbonate with excess of 30% hydrogen peroxide solution. It is concluded that zinc perhydrate generally consists of a mixture of substances, derived from the two compounds $\text{Zn}(\text{OH})_2$ and H.O.Zn.O.Zn.OH , the hydroperoxides being of the types HO.Zn.O.OH and $\text{Zn}(\text{OH}).\text{O.Zn.O.OH}$. Hydrogen peroxide, since it decomposes zinc carbonate, acts as a monobasic acid.

Disodium nitrite; an additive compound of sodium nitrite and sodium. E. B. Maxted. Chem. Soc. Trans., 1917, 111, 1016—1019.

A BRIGHT yellow compound of the empirical formula, Na_2NO_2 , was prepared by two methods:—(1) A known weight of sodium was dissolved in anhydrous liquid ammonia, and freshly fused, finely divided sodium nitrite added in the proportion of one mol. to each atom of sodium. The completion of the reaction was marked by the discharge of the deep blue colour. The disodium nitrite settled out as a yellow precipitate, from which the ammonia was removed by evaporation. (2) By electrolysis of sodium nitrite in anhydrous liquid ammonia, using platinum electrodes, a yellow deposit of disodium nitrite was obtained on the cathode. The compound is very readily decomposed by water.—L. A. C.

Hydrous ferrous oxide sols; Precipitation, stability, and constitution of—. I. M. Neidle. J. Amer. Chem. Soc., 1917, 39, 2334—2350. (See also this J., 1917, 290.)

PERFECTLY clear colloidal solutions of hydrous ferrous oxide were prepared as follows:—1 grm.-equivalent of ferrous chloride was dissolved in 400 c.c. of water, the solution filtered and completely oxidised with 3% hydrogen peroxide. This solution, diluted to 4 litres, was dialysed in the cold for three days, and then portions of it, further diluted, dialysed at 80° C. for five days. By diluting equal portions of these solutions with standard dilute hydrochloric acid and distilled water to the same volume, a series of solutions was obtained having a constant iron, and variable chlorine content; similar series were obtained, each with a different iron content. The relative stability of these solutions was measured by the amount of potassium sulphate necessary for their complete precipitation. The data show that for a given iron concentration the stability increases with the chlorine content, while for solutions of given purity, i.e., given ratio, equivalents Fe: equivalents Cl, the stability decreases as the concentration increases. The maximum purities corresponding to four iron concentrations were obtained by graphical extrapolation. The maximum purity obtainable decreases as the iron concentration increases. Clear hydrous ferric oxide sols containing ferric ions are concluded to contain a colloidal oxychloride of definite ratio, $21(\text{Fe}/\text{Cl})$: 1 (Cl); further evidence of the formation of this colloid is deduced from the behaviour of ferrous sulphate solutions when oxidised by air. Decrease in the concentration of the ferric ion with progressive removal of hydrochloric acid from the oxychloride sols results in hydrolysis and the formation of a series of colloids of increasing Fe: Cl ratio. Lack of agreement between colloid precipitation data of different investigators is shown to be due very largely to the varying purities and concentrations of solutions employed.—L. A. C.

Hydrogen peroxide. V. Macri. Boll. Chim. Farm., 1917, 56, 417—418. J. Chem. Soc., 1917, 112, ii., 529—530.

HYDROGEN peroxide prevents the precipitation of phosphomolybdate when solutions of ammonium

molybdate and phosphoric acid are mixed. Hydrogen sulphide does not affect the reaction between hydrogen peroxide and chromic acid if the chromic acid is added to the solution of hydrogen peroxide and hydrogen sulphide. When hydrogen peroxide is treated with ammonia in presence of calcium chloride, a precipitate, CaO_2 , is formed. When hydrogen peroxide is evaporated in a platinum dish in the presence of hydrogen chloride, a certain amount of chloroplatinic acid is formed. The estimation of free acid in hydrogen peroxide may be effected by titration with permanganate, the end-point being shown by the appearance of a brownish-yellow coloration.

Solubilities of anthracene, anthraquinone, p-bromobenzene, phenanthrene, and iodine in various solvents. Hildebrand and others. See III.

PATENTS.

Nitric acid; Production of—. E. C. R. Marks, London. From Tentelev Chemical Works, Petrograd. Eng. Pat. 110,637, Nov. 21, 1916. (Appl. No. 16,671 of 1916.)

COMMERCIAL nitric acid is added gradually to a hot solution of nickel or zinc nitrate (or other suitable nitrate) of such a concentration that it can be maintained at 126° to 170° C., or an even higher temperature. The pure acid evaporates immediately without decomposition, leaving impurities (e.g., sulphuric acid and iron) in the solution, and is condensed.—L. A. C.

Oxalic acid and oxalates; Production of—. Allen Bros. and Co., Ltd., and C. F. Cross, London. Eng. Pat. 110,837, Jan. 4, 1917. (Appl. No. 223 of 1917.)

THE bark of *Shorea robusta*, known as "sal bark," which contains calcium oxalate, is leached with water to dissolve the tannins and then treated with a cold 10% solution of hydrochloric acid for three hours. The liquor is separated, and the bark washed with water which is added to the liquor. The mixture is concentrated by boiling, the hydrochloric acid distillate collected, and the residue neutralised with lime to precipitate the calcium oxalate. The hydrochloric acid may be replaced by sulphuric acid of 5% strength and the mixture boiled. The liquid is neutralised with lime, and the mixed calcium sulphate and oxalate treated with sulphuric acid of 20% strength to convert the oxalate into sulphate and liberate oxalic acid. When the bark is required to be disintegrated for paper making, the acid may be replaced by sodium carbonate of 10% strength at a pressure of 50 lb. per sq. in. The liquor is then separated and treated for the recovery of oxalic acid.—W. F. F.

Hydrofluoric acid from silicon fluoride; Manufacture of—. H. F. Chappell, New York, N.Y. U.S. Pat. 1,244,032, Oct. 23, 1917. Date of appl., Apr. 17, 1917.

AN aqueous solution of hydrofluosilicic acid is heated to convert it into hydrofluoric acid, silicon fluoride, and water vapour. The resulting products are maintained at such a temperature that the water vapour acts on the silicon fluoride to produce hydrofluoric acid and silicon hydroxide.—J. H. P.

Salt; Process of recovering— from its admixture with impurities in crude brine. W. W. Skinner and W. F. Baughman, Washington, D.C. U.S. Pat. 1,244,380, Oct. 23, 1917. Date of appl., July 14, 1917. (Dedicated to the public.)

PURE sodium chloride is separated from admixed impurities in crude brine, particularly barium salts,

by treating the brine with sodium sulphate and lime and pumping air through the mixture. This ensures thorough mixing, and ferrous bicarbonate in the brine is decomposed into the hydroxide, which is precipitated along with barium sulphate. Pure sodium chloride is obtained from the resulting liquor by crystallisation.—J. H. P.

Titanium-oxygen compounds; Process of producing —. Det Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank, Christiania, Norway. Eng. Pat. 102,059, Oct. 30, 1916. (Appl. No. 15,471 of 1916.) Under Int. Conv., Nov. 1, 1915.

TITANIFEROUS iron ores (ilmenite, etc.) are partially decomposed by a quantity of decomposing agent (mineral acid, fusion with alkali carbonates, bisulphates, etc.) less than that which is theoretically required. The material thus obtained is lixiviated with a solution of salts of titanium and iron obtained by lixiviation of another portion of decomposed material. The residue is decomposed further and again lixiviated, the process being repeated until extraction of titanium is complete. Lixiviation is carried out on the counter-current principle, using the smallest possible quantity of solvent, and keeping the solutions cold. A small quantity of water only is used for the final washing. By this means, after precipitation of titanium hydroxide (by heating), the concentration of iron and decomposition agent in the residual liquid is high; thus recovery of these substances is simple. The same series of operations may be performed any number of times on the product in order to obtain titanium oxide of any desired degree of purity.—L. A. C.

Potassium; Process of treating minerals or rocks containing —. O. Rayner, Paris. Eng. Pat. 102,493, Nov. 22, 1916. (Appl. No. 16,720 of 1916.) Under Int. Conv., Nov. 30, 1915.

MINERAL or rock containing potassium is mixed with carbonaceous ash of marine plants and heated to 800°–1100° C. in a current of air. Iodine is distilled off and is condensed, and the residue is leached with water to dissolve potassium compounds, which may then be treated as desired. The residue containing aluminium and silicon is treated with dilute acid to dissolve and recover the aluminium compounds.—W. F. F.

Ammoniacal liquor; Extraction of cyanides from —. H. Baker, Barrow-in-Furness. Eng. Pat. 110,819, Nov. 25, 1916. (Appl. No. 16,906 of 1916.)

CRUDE ammoniacal liquor from coal gas manufacture is boiled with one or more of the alkaline compounds of potassium, calcium, or sodium such as the oxide, hydroxide, or carbonate, with or without the addition of any other alkali or alkaline-earth. Ammonia is liberated and recovered in the usual way, and the residual liquid is boiled with any salt of silver, aluminium, tin, or nickel, which precipitates the corresponding cyanides of the metals.—W. F. F.

Air; Method and apparatus for [electrically] treating —. W. T. Hoofnagle, Glen Ridge, N.J., Assignor to Electro-Chemical Products Co., New York. U.S. Pat. 1,243,524, Oct. 16, 1917. Date of appl., May 25, 1915.

A CURRENT of air, or other gas to be treated electrically, is passed successively through a water chamber where water vapour is added in excess of the amount required to saturate it, and a reaction chamber at a pressure below that of the atmosphere. An exhaust mechanism is connected to the re-

action chamber, and means are provided for shunting any desired part of the current of gas past the water chamber.—B. N.

Lime; Process of slaking —. W. E. Carson, Riverton, Va. U.S. Pat. 1,244,421, Oct. 23, 1917. Date of appl., Sep. 28, 1915.

COMMUNUTED lime is placed in a tall, strong-walled receptacle and is mixed with sufficient water to form a slurry, without leaving a damp or moist final product. The materials are mixed quickly enough to prevent substantial hydration prior to the formation of the slurry, which is then run rapidly into a tall vertical vessel where the reaction is allowed to proceed quietly, under its own pressure, for at least 8 hours.—A. B. S.

Sulphuric anhydride and sulphuric acid; Production of —. C. Ellis, Montclair, N.J., U.S.A. Eng. Pat. 110,776, Oct. 2, 1916. (Appl. No. 13,985 of 1916.)

VIII.—GLASS; CERAMICS.

Gas firing and the glass industry. J. W. Cobb. Soc. Glass Tech., Nov. 21, 1917.

IN the old types of glass furnace, where the fuel is burnt close to the work, the heat available is only a small percentage of the whole, due to the fact that the fall in temperature of the flame from entry to exit is only small. There is great danger, too, in the light ash which is formed, being carried forward to exercise its baneful effects as a flux on furnace linings, etc., and also its decolorising effects on any glass with which it may come in contact. The waste heat from direct-fired furnaces may be utilised, say for steam raising, but only in a makeshift manner. Attempts, too, have been made to utilise this waste heat to pre-heat the air required for combustion, but owing to difficulties of furnace design these attempts are far from being successful. A fact often lost sight of in heating air by passing it through hot flues, is that the air is transparent to radiant heat and is only affected by actual contact with the hot walls of the flue. Thus pre-heating by passing air through hot flues of large cross-section is very ineffective. A great step in furnace work was the introduction of the Siemens regenerative furnace. Coal is burnt away from the furnace proper with the formation of carbon monoxide, which is delivered into the furnace together with air, and burns there to carbon

dioxide. In addition, the waste hot gases leaving the furnace are made to pass through chambers filled with chequered brick work. By suitable means, the ingoing air and gas is afterwards passed through this hot brick work and so is heated before entering the furnace, resulting in an enormously increased temperature of combustion. In addition the regenerative chambers serve as filters for the dust or ash in the gases. In the Siemens producer the depth of fuel is large and there is considerable frictional resistance to movement of gas. The use of forced draughts causes the temperature to rise to such an extent as to cause clinkering. In order to keep down the temperature near the fire bars, steam is blown in, preventing clinkering, and also forming a mixture of carbon monoxide and hydrogen, the production of which is accompanied by an absorption of heat from the layer of hot coal near the fire bars. There are limits to the amount of steam that can be blown in; any excess results in the formation of carbon dioxide, or may even pass on into the furnace chamber unaltered, where it has the harmful effects of an inert gas. The best proportions of air and steam have to be determined by practice. Details were given of the Taylor producer, the Kerpely producer, and producers of the Mond type. The production of ammonia, low temperature regeneration, and the washing of producer gas by the Mond system were also discussed.

Pottery ovens; Firing of —. S. T. Wilson. Trans. Ceram. Soc., 1917, 16, 304—316.

IN firing china biscuit an oxidising atmosphere containing about 50% excess air in the oven is essential. To secure this, the doors of the fireplaces and the dampers are opened, and the fires are gradually allowed to get hotter until the contents of the oven are at red heat, after which the fire must be regulated carefully. The length of flame is controlled by varying the space above the fuel in the fireplace and by adjusting the port-holes admitting hot air. In an up-draught oven, the flame should be kept at a length which causes a short clear flame to issue from the shoulder holes as long as possible. When the "bags" begin to cool and change colour, more coal is supplied to the oven, this process of heating and cooling being repeated until trials show that the goods are slightly translucent. After this, the flame is allowed to reach just to the shoulder holes and the heating is continued until the top trials are satisfactorily fired. The bottom of the oven is then finished by admitting more air over the fuel and driving the flames to the lower part of the oven. There should be a slight outward pressure at the level of the top trial hole, during full fire. A down-draught oven is fired similarly, but as there are no shoulder holes for guidance, the length of the flame is judged by its appearance in the sight hole. As only about 9% of the heat of the fuel used is employed in an actually useful form, it is important to save the 91% of heat lost. A continuous regenerative oven of the Siemens type, according to the author, is impracticable for pottery because it does not allow sufficient time for the oven temperature to become uniform, and some saggers would have a temperature nearly equal to that of the flame itself. When hot air is used to facilitate combustion this difficulty is increased and the dimensions of each chamber in the oven would have to be so small that the fall in temperature of the gases during their path across the firing space will not exceed the limits which the ware will allow. This would make the chambers impracticably small, and the author concludes that the only type of continuous oven likely to be suitable for china and earthenware is a tunnel oven of small dimensions.—A. B. S.

Firebricks; After-contraction or after-expansion of — in oxidising and reducing atmospheres. J. W. Mellor. Report to Refractory Materials Committee of Institution of Gas Engineers. Trans. Ceram. Soc., 1917, 16, 268—269. (See this J., 1917, 701.)

SILICA bricks tend to expand less and fireclay bricks to contract more in a reducing than in an oxidising atmosphere on account of ferrous compounds having a greater fluxing effect than ferric compounds. The magnitude of this fluxing effect depends on the strength of the reducing atmosphere, the rate of penetration of the gases into the bricks, and the temperature and time of exposure to the reducing atmosphere. For these reasons, it is desirable that tests of the contraction of clay on heating should be conducted in a neutral atmosphere.—A. B. S.

Firebricks; Hot and cold sizes of —. J. W. Mellor. Report to Refractory Materials Committee of Institution of Gas Engineers. Trans. Ceram. Soc., 1917, 16, 270—273. (See this J., 1917, 701.)

MEASUREMENTS of the sizes of bricks at various temperatures were made with Coppée's apparatus (J. Iron and Steel Inst., 1915, 88, 32) consisting of two cathetometers mounted on the same base, each focussed on a pointed platinum wire fitted tightly into a vertical saw-cut near the end of the brick to be measured. The distances apart of the cathetometers and therefore of the platinum points is measured by means of an "invar" scale on a separate stand. If a brick is imperfectly burned, the effects of an after-contraction or after-expansion are superposed on the effects of thermal expansion, so that the brick does not regain its original volume on cooling; the difference between the cold sizes of the brick before and after heating show the magnitude of the after-contraction or after-expansion. In all such cases, a brick may show a smaller volume at (say) 1180° C. than at 1060° C., the effects of thermal expansion being wholly masked by the after-contraction. The coefficient of expansion of fireclays and silica bricks decreases with rise of temperature. Thus one fire-brick had a coefficient of expansion of 0.0000081 from 15° to 940° C. and 0.0000060 from 15° to 1180° C.—A. B. S.

Refractories for steel furnaces from the consumer's point of view. W. J. Brooke. Trans. Ceram. Soc., 1917, 16, 205—236.

Silica bricks. Some silica bricks exhibit excessive expansion, causing the walls or roofs of furnaces to break from excessive lateral stresses. This expansion is usually due to the brick not having been dried or burned sufficiently during manufacture. The "running" or fusion of silica bricks may be due to inferior material or to careless manipulation of the furnace. Softening or breaking away in lumps sometimes occurs without any sign of true fusion or spalling; this may be due to the body of the brick being coarsely ground and the proportion of binding material out of balance to the average constitution of the bulk. "Spalling" is probably due to insufficient burning and consequent incomplete inversion of the silica. The author suggests that the roof of a large steel furnace is the best place to test silica bricks, specially severe conditions existing between the crown and skew-back over the tap-hole for a distance of two to five feet on either side of the transverse centre line of the furnace, and at this point all the defects previously enumerated may be observed. The abrasion of bricks by furnace gases is usually due to the velocity of the moving gases, especially where one stream is broken into several smaller ones or a change occurs in the

direction of the gases. Alternate reducing and oxidising conditions are probably of secondary importance, but a kind of "surface combustion" may be highly destructive to brickwork. For furnace linings, bricks and blocks must be accurate in size and shape so as to make close joints. A variation in size of $\frac{1}{4}$ in., absent corners, or lack of "squareness" are all serious defects which ought not to occur, and manufacturers cannot attach too much importance to avoiding them. The author has found that certain silica bricks made of "outcrop quartzite" containing 92% SiO₂ are quite satisfactory in an iron blast furnace.

Magnesite bricks are usually employed in the bottom of the furnace, below the basic lining. They should be perfect in shape and size, of fine texture, with low porosity, great hardness and density, and a finely crystalline semi-vitreous fracture; they should "ring" like metal and be free from tendency to spall. The Styrian bricks fulfil all these requirements, but are costly, and supplies were always irregular. British-made magnesite bricks, in the past, have been of very poor quality, partly owing to the attempt of British manufacturers to burn magnesite bricks in kilns built of silica instead of magnesite and at a much lower temperature. The Austrian bricks owe their value to fine grinding, high preliminary burning, powerful hydraulic pressure in making, and very high temperature in burning so as to secure the formation of β -magnesia. If iron oxide is required to form a bond, it may be added in the form of "waste pickle." Typical analyses of magnesite bricks, silica bricks, and ganister are cited.—A. B. S.

Furnace conditions; Effects of—on basic refractories used in smelting operations. A. Wasum. Verh. Vereins Beförd. des Gewerbleisses, 1884, 63, 104. Trans. Ceram. Soc., 1917, 16, 317—326.

Four series of bricks were made using (1) dolomite, (2) lime, (3) magnesia, and (4) magnesite as the chief ingredient, with one of the following bonds: clay, silica, calcium phosphate, ferric oxide, ferrous oxalate, hammer scale (ferrosoferric oxide), ferric phosphate, ferrous phosphate, trimanganic tetraoxide, and basic converter slag. The bricks were fired in a commercial oven along with basic bricks at "the highest white heat." The following conclusions were reached. Good bricks may be made without a bond from dolomite, limestone, or magnesia, but not from magnesite as it does not possess sufficient plasticity. By the addition of clay up to 5%, still better bricks may be made and magnesite may then be used. The bricks must be burned for a long time at a "very high white heat." Dolomite and lime bricks produced without a bond, have a durability of about three weeks in dry air; their durability is considerably increased by the addition of clay as bond. Magnesia and magnesite bricks, with or without a clay bond, will last over three months in dry air. A high burning temperature is essential to durability. The dolomite, lime, and magnesite bricks contracted 24% on burning, but those made of strongly calcined magnesia only contracted 1%. Lime and dolomite bricks are strongly attacked by slags and the oxides of iron, much less so by silica, phosphoric acid, and manganese. The foregoing results are strongly in favour of highly calcined magnesia as the best basic material, but the cost of such magnesia bricks is so great that to be profitable their durability in use should be three or four times as great as that of dolomite or lime bricks. According to the author this is not the case.—A. B. S.

Fireclay goods; Black cores in—. J. W. Mellor. Trans. Ceram. Soc., 1917, 16, 259—267.

WHEN clays are heated so rapidly that surface

fusion occurs before the carbonaceous material in the interior has been fully oxidised, black cores are produced. To prevent the formation of these cores, ventilation must be good and the heating must be slow during the oxidation period, especially from 600° to 900° C., at which temperature the capillaries in the material begin to close. The precise boundary temperature depends on the clay and must be found by trial. If the temperature has been raised to 1000° C. without oxidising all the carbon, any ferrous compounds present will probably unite with the clay to form a fusible slag and no subsequent firing will then remove the core. In bad cases the gas bubbles entangled in the fused slag cause the bricks to swell and become lighter than an equal volume of water. Other things being equal, plastic-made bricks of fine texture or with coarse particles of bituminous matter will form cores more readily than dry-pressed and more porous bricks, with woody carbonaceous matter (sawdust).—A. Glass or like material; Process for drawing molten— in cylindrical form [tubes and rods]. E. C. R. Marks, London. From The Libbey Glass Co., Toledo, Ohio, U.S.A. Eng. Pat. 110,642, Nov. 29, 1916. (Appl. No. 17,133 of 1916.)

THE molten glass flows around a hot, inclined, rotating blowpipe, then through a hot, rotating, conical passage surrounding a part of the blowpipe, thus regulating the thickness of the stream, and through a cooler rotating cylinder; both the cone and cylinder are made of fireclay. The glass, which is now in the form of a soft tube, is supported on a long bench and is drawn at uniform speed (e.g., 140 ft. per min.) by any suitable mechanism, and is then cut into pieces of the desired length. The glass tubes thus produced have walls of uniform thickness; the glass solidifies before it has time to become distorted, and the finished tubes are more perfect in form and contain less air-bubbles than those produced in the customary manner. The air-pressure used is very small, but it must be constant. Solid rods may be made by shutting off the air-supply.—A. B. S.

[Glass lehr.] Channel oven, drying oven or the like. H. I. F. Strandh, Forserum, Sweden. U.S. Pat. 1,243,777, Oct. 23, 1917. Date of appl., Dec. 21, 1915.

A LEHR or tunnel oven for annealing glass wares is provided with a rectangular track, one side of which extends within the lehr and the opposite side extends outside it, forming outlet and inlet races. The goods to be annealed are carried on boards fitted with rollers which continuously rest on the track. The track is fitted with rollers at right angles to those on the boards and arranged in such a manner that only rolling friction between the boards and the races is obtained not only whilst transporting the boards on the different races, but also at every moment of the transfer between two adjacent races.—A. B. S.

Casting pottery and like articles; Process of—. B. J. Allen, Blythe Bridge, Staffs., and R. Y. Ames, Gidea Park, Essex. Eng. Pat. 110,649, Dec. 11, 1916. (Appl. No. 17,787 of 1916.)

THE articles are made by pouring a suitable slip into a porous mould encased with iron, and reducing the pressure between the mould and the casing. The rate of evaporation of the absorbed fluid and

the absorbing power of the mould are thus increased and a rapid deposit of normal thickness or a deposit much thicker than can be obtained with ordinary moulds is produced. The absorbing power of the mould may also be supplemented by applying perforated or porous vessels containing dried calcium chloride and the like so as to produce an uneven or graduated deposition of the casting material. The jacket or casing may be provided with studs to support the mould and also facilitate the removal of the moisture from those parts of the mould where the deposit is required to be thickest and *vice versa*, so that articles of varying thickness may be cast without special treatment of the mould. In casting crucibles or open-top glass-house pots, it is preferable to use a mould to give both the inside and outside shapes, and to apply suction to both the inside and outside mould. The inside mould is removed as soon as the deposit is sufficiently hard. In making large gas retorts or furnace blocks, a product with an open, porous structure may be obtained, or a mixture which is too thick and plastic to cast under ordinary conditions may be used. (See also this J., 1917, 549.)—A. B. S.

Abrasive articles; Method of making —. H. Urtel, La Salle, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,243,783, Oct. 23, 1917. Date of appl., Jan. 31, 1914.

ABRASIVE articles, made of a mixture of fused crystalline alumina and a bond containing liquid sodium silicate and zinc oxide, with or without flint, are fired to a temperature sufficiently high to form a double silicate of sodium and zinc which is insoluble in water, but not to dissolve alumina in amount sufficient to dull the grains of abrasive. —A. B. S.

Firebrick and furnace linings; Composition for making —. R. R. Zell, Birmingham, Ala., Assignor to Silicrete Refractories Co., Irondale, Ala. U.S. Pat. 1,244,275, Oct. 23, 1917. Date of appl., Feb. 8, 1917.

A REFRACTORY material containing "silicrete" 100, aluminium hydroxide 5, dehydrated gypsum 5 parts, and sufficient of a 10% solution of caustic potash to render the mass plastic, but not alkaline. —A. B. S.

Dental cement. W. S. Crowell, Philadelphia, Pa., Assignor to The S. S. White Dental Manufacturing Co. U.S. Pat. 1,244,296, Oct. 23, 1917. Date of appl., Jan. 26, 1917.

A DENTAL cement consisting of zinc oxyphosphate or other cement powder and an acid phosphate liquid containing a mercury salt.—A. B. S.

IX.—BUILDING MATERIALS.

Potash from cement dust. Canadian Chem. J., 1917, 1, 161.

FROM theoretical considerations and practical data relating to 20 cement factories in Canada, it is

estimated that, per year of 300 working days, 21,555 short tons of potash (K_2O), valued at nearly \$11,000,000 (£2,291,700), is at present lost in the form of dust containing 12% K_2O in the case of the dry, and 21% K_2O in the wet process of manufacture. The combined rated daily capacity of the plants in question is 47,900 barrels, a barrel being about 350 lb. and representing 625 lb. of raw mix containing 9.8% K_2O . It is assumed that 60% of the potash entering the kilns is liberated and expelled with the gases. The potash content of the feed could be increased to about 2.5% (by the addition of felspar, etc.), without detriment to the clinker produced. Of the numerous methods tried for the collection of cement mill dust, the Cottrell process of electrical precipitation has proved the most successful commercially. This process is already in use in four plants having a combined rated capacity of 15,500 barrels per day, and is now being applied to four others having a combined rated capacity of 7000 barrels per day.—W. E. F. P.

PATENTS.

Preserving wood; Method of —. H. Foersterling, R. N. Sargent, and F. A. Kaufmann, Perth Amboy, N.J., Assignors to the Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,242,168, Oct. 9, 1917. Date of appl., Dec. 27, 1915.

Wood is preserved by precipitating an insoluble metallic cyanide (e.g., copper cyanide) within its intercellular spaces; this may be effected, for example, by causing first a solution of copper sulphate and then one of sodium cyanide to enter the wood.—A. B. S.

[*Cement*] *slurry; Treatment of* —. C. Pontopidan, Brooklyn, Assignor to F. L. Smidth and Co., New York. U.S. Pat. 1,242,236, Oct. 9, 1917. Date of appl., Sep. 18, 1915.

SLURRY for use in the manufacture of Portland cement is mixed with an electrolyte, such as sodium carbonate, to increase its fluidity and reduce its water content.—A. B. S.

Mineral wool; Art of making —. W. Fay, St. Louis, Mo. U.S. Pat. 1,242,537, Oct. 9, 1917. Date of appl., Feb. 23, 1917.

MINERAL wool is made by forcing a hot dust-settling fluid, such as a mixture of oil and steam, at a high velocity into a stream of molten scoriaceous material. The mineral wool-fibres and fluid are projected into a receiving chamber, and the fluid is allowed to pass out through restricted openings so as to create a pressure in the chamber and cause the fibres to float or circulate slowly but freely in the fluid.—A. B. S.

Cement, etc.; Process for the manufacture of —. L. P. Basset, Paris. U.S. Pat. 1,241,280, Oct. 23, 1917. Date of appl., Mar. 4, 1914.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel; Special properties of eutectoid —. P. Y. Saldau. Rev. Soc. russe de Mét., 1916, 1, 112—148. Rev. Mét., 1917, 14, Ext., 193.

FROM a study of different carbon steels, having lamellar or granular, pearlitic structures, it is concluded that, in physical properties, eutectoid steel is differentiated sharply from other steels of similar composition. In eutectoid steel, the hardness, resistivity, and resistance to rupture and compression are at the maxima after annealing, the lamellar pearlite not being rendered granular by heating at 700° C. for 7 hrs. A rectilinear diagram is not applicable for representing the physical properties of iron-carbon alloys in the eutectoid region. These properties are probably associated with the high degree of dispersion (i.e., ratio of surface to volume) of the metal in the eutectoid region of the iron-carbon series.—W. E. F. P.

Chrome steel; Some peculiarities in the manufacture of — in the Martin furnace. N. N. Menchikh. Rev. Soc. russe de Mét., 1916, 1, 176—188. Rev. Mét., 1917, 14, Ext., 233—235.

IN the author's experience, the chromium content of the metal produced in the Martin furnace depends entirely on the operation of the furnace and not on the initial chromium content of the charge. The high loss of chromium (often two-thirds of the total) experienced in ordinary working occurs mainly during fusion, particularly if the atmosphere is sufficiently oxidising. When fusion is complete, the chromium content of the metal bath increases with the temperature at which the operation is continued. The author is of opinion that, at high temperatures, the chromium of the slag passes into the metal in the form of an oxide (other than that present in the slag), which is very stable and soluble under these conditions.

—W. E. F. P.

Steel tools; Use of high-speed cast —. Grenet. Rev. Mét., 1917, 14, 547—550.

STEELS of the following composition are described:

	A. Extra hard.	B. Hard.	C. Normal.
Carbon	2.7	1.2	0.7
Chromium	19.4	6.6	3.5
Tungsten	24.9	23.0	19.0
Vanadium	0.4	0.8	0.8

Steel A was cast in rectangular steel moulds 10 mm. wide and 15 mm. deep; the lower, thoroughly chilled part was used. The alloy was very brittle unless annealed for 2 hours at 550° C., but even after annealing it could only be used with the greatest care and could not be utilised in the works. Steel B was cast and annealed like A; on semi-hard steel it could be used at much higher speed than the best high-speed steels and lasted 4—10 times longer than the best forged tools. It was brittle enough to require cautious use. The cutting speed of steel C was not much higher than that of forged tools, while it lasted about 1½ times as long. The brittleness was not pronounced enough to render annealing indispensable, but annealing at 500° C. is recommended. The presence of manganese is prejudicial to hardening, as it prevents the change from γ - to α -iron during the chilling.—W. R. S.

Gold; Effect of sulphides on solutions of — in potassium cyanide. V. Pasoukhine. Rev. Soc. russe de Mét., 1916, 1, 161—172. Rev. Mét., 1917, 14, Ext., 237—240.

CONTRARY to the statements of certain English

authors, artificial and natural sulphides of copper, iron, lead, zinc, etc., were found not to act as precipitants of gold from cyanide solutions. As confirming this result, 100, 75, and 65 % of the gold present in artificially-prepared, auriferous sulphides of copper, iron, and lead, respectively, was extracted by a dilute solution of potassium cyanide.—W. E. F. P.

Furnace for melting brass; Resistance type —. T. F. Baily. Amer. Electrochem. Soc., Oct., 1917. [Advance copy.] 9 pages.

DETAILS of running tests of an electric tilting furnace of the resistance type are given. The furnace is of the non-crucible type, having a cylindrical shell provided with inner walls and roof forming the furnace chamber. The bottom of the chamber provides a bowl-shaped hearth for the metal when melted. The resistance element is contained in a circular trough made of refractory material; in this trough the resistance material (broken carbon) forms contact with the electrodes, which are placed diametrically opposite each other with their ends projecting into the trough. The rated electrical capacity is 105 kw. for a furnace 7 ft. in diam. having a hearth capacity of 1500 lb. and an average melting rate of 600 lb. per hour. The quality and uniformity of the product were satisfactory. On the basis of the power consumed, viz., 450 and 300 kilowatt-hours per short ton of bearing bronze and cartridge brass (average of six tests each), respectively, the melting costs compared favourably with those in non-electric furnaces.—W. E. F. P.

[Bronzes, etc.] *Test-bars and actual castings; Some comparative tests on* —. W. M. Corse and G. F. Comstock. J. Amer. Inst. Metals, 1917, 11, 250—256.

WITH a view of preventing the application of specifications based on standard test-bar results to test-pieces cut from actual castings, attention is drawn to a number of cases in which considerable discrepancies were shown in the tests of various bronzes and aluminium alloys.—W. E. F. P.

White metal alloys; Analysis of —. Determination of lead, copper, and antimony. R. Howden. Chem. News, 1917, 116, 235.

Lead. One grm. of the alloy is dissolved in nitrohydrochloric acid, 5 c.c. of concentrated sulphuric acid and 1 grm. of tartaric acid are added, and the mixture is heated until red fumes cease to be evolved. The mixture is then cooled and diluted and the lead sulphate collected, washed, and weighed. **Copper.** The filtrate from the lead sulphate is treated with sulphur dioxide and the copper precipitated as cuprous iodide or thiocyanate. The precipitate is collected, dissolved in nitric acid, and the copper determined iodometrically. **Antimony.** One grm. of the alloy is dissolved in hydrochloric acid with the addition of potassium chlorate, and the solution is treated with stannous chloride solution, added drop by drop, until the yellow colour due to the copper is destroyed; air is then passed through the solution for about 20 mins. in order to re-oxidise the copper. One drop of methyl-orange solution is then added and the mixture titrated with potassium bromate solution until the colour of the indicator disappears. The bromate re-oxidises the antimony, and if the bromate solution contains 4.639 grms. of potassium bromate per litre, each c.c. is equivalent to 1 % of antimony when 1 grm. of alloy is taken for the determination.—W. P. S.

[Tin and wolfram ores.] *Slime treatment on Cornish frames, with particular reference to the effect of surface.* S. J. Truscott. Inst. Min. and Met., Nov., 1917. [Advance copy.] 68 pages.

LABORATORY tests with slimes containing tinstone

or wolfram were conducted on a frame 16 in. wide and 30 in. long, covered with pine wood, cement, plate glass, fluted glass, or rubber. The following conclusions were reached. A suitably adjusted, transversely fluted surface is more effective than a plane surface, the flutes causing the mineral to deposit at the upper end of the frame, where it gradually accumulates and continually displaces the gangue from the next lower flute. The flutes tend strongly to prevent channels, banks, and irregular distribution which would lead to loss of mineral. They provide a bed of mineral, which is the most effective means of holding fine material. The size and shape of the flutes must be adjusted to the kind of material treated; if they are too deep, the gangue particles settled at the bottom do not become dislodged by subsequently arriving mineral particles. The conclusions apply to wolfram as well as to cassiterite. Among plane surfaces wood was the most effective material, but its surface wears in the course of time. The size of the material should be as uniform as possible, *i.e.*, all finer than 120-mesh, at least 80% passing a 200-mesh. The inclination of the frame and the pulp ratio are interdependent, and the best conditions, as well as the length of the frame, must be ascertained in each case. Increase in temperature of the water, like lack of water, gives a bulkier but less valuable concentrate. An increase in the rate of pulp feed makes a richer concentrate at the cost of lower recovery, but the tailing can again be subjected to a similar treatment. It is recommended to adopt the principle of taking out a sufficiently rich concentrate which will require a minimum of further treatment, and repeating this process on each successive tailing. By this means and the use of fluted surfaces, an improvement of 10% in the slime recovery may be expected.—W. R. S.

PATENTS.

Ingot-iron and steel; Manufacture of —. Deutsch-Luxemburgische Bergwerks- u. Hütten-Akt.-Ges., Bochum, and A. Klinkenberg, Dortmund, Germany. Eng. Pat. (A) 105,548, Mar. 6, 1917. Under Int. Conv., Mar. 27, 1916. (Appl. No. 3316 of 1917), and (B) 105,902, Mar. 7, 1917. Under Int. Conv., Apr. 18, 1916. (Appl. No. 3397 of 1917.)

(A) IN the manufacture of ingot iron and steel by deoxidation of molten metal rich in oxygen, carbohydrates, *e.g.*, sugar, in the proportion of 2.5 parts to steel 1000 parts, may be added to the molten metal. (B) In the process described in (A) for making ingot iron and steel, the carbohydrates for deoxidising may consist of packages of wood wool, shavings, sawdust, or the like, which are placed in the tapping ladle just before pouring in the molten metal.—W. F. F.

Malleable cast iron or steel; Furnaces for the manufacture of —. L. Geuze, Paris. Eng. Pat. 103,996, Feb. 2, 1917. (Appl. No. 1717 of 1917.) Under Int. Conv., Feb. 8, 1916.

A FURNACE for the manufacture of malleable cast iron or steel comprises three adjoining communicating chambers, the central melting chamber being heated by generator gas. Steel or iron turnings or scrap are placed in one of the side

chambers and preheated by hot gases from the central chamber, and cast iron is similarly preheated in the other side chamber. These charges are gradually pushed into the central chamber by the addition of fresh charges of material, and the mixture is melted and run off.—W. F. F.

Steel; Compound for tempering —. C. C. Trinkle, Romney, Ind. U.S. Pat. 1,213,899, Oct. 23, 1917. Date of appl., Feb. 19, 1917.

THE compound comprises sodium bicarbonate, willow charcoal, sal ammoniac, sulphur, copperas, and table salt.—T. H. B.

Carbonising metal articles; Process and apparatus for —. W. Fennell, Gloucester, Eng. Pat. 110,937, Nov. 7, 1916. (Appl. No. 15,959 of 1916.)

A FIREBRICK conduit passes vertically through a furnace chamber so that its middle portion is strongly heated. Articles to be carbonised, mixed with carbonising material, are fed into the conduit from a hopper at the top so that the conduit is practically full. A rotating plate is arranged just below the open lower end of the conduit, and a fixed scraper removes the articles and material from the plate so as to allow a gradual discharge from the conduit on to the plate. The rate of discharge may be varied by adjusting the position of the scraper, or the speed or height of the table. Alternatively an adjustable sleeve may be provided on the lower end of the conduit.—W. F. F.

Copper and nickel; Electro-deposition of — from solutions obtained from ores. M. V. Garin, Paris. Eng. Pat. 104,678, Feb. 23, 1917. Under Int. Conv., Feb. 29, 1916. (Appl. No. 2701 of 1917.)

IN the electro-deposition of copper and nickel from weak solutions containing sulphurous acid, obtained from ores, an insoluble anode, *e.g.*, of lead, is used and the cathode surface is continuously rubbed or wiped. The rubber is of animal or vegetable fibre carrying filaments of gelatin. If the gelatin has not first been rendered insoluble, the temperature of the bath is kept below 20° C. The rubber may also be formed of organic membranes containing gelatin which gradually dissolves, *e.g.*, parchment skins. The cathode may be a rotating horizontal cylinder, and the anode may surround it except at the top where the rubber rests on its surface. Hydrogen bubbles are thus removed from the surface of the cathode and deposition of copper sulphide is prevented.—W. F. F.

Ores; Flotation process of treating — and apparatus for use therein. K. Sundberg, Guldsmidshyttan, Sweden. Eng. Pat. 110,717, June 4, 1917. (Appl. No. 8002 of 1917.)

ORE pulp and oil are fed into the first of three adjacent chambers, and the mixture is caused to rotate horizontally by jets of air from suitable nozzles. The mixture passes through an opening in the side of the chamber into a vessel having a conical bottom from which the foam overflows, and the heavier material passes to the second chamber adjacent to the first chamber. It is subjected to similar treatment in this chamber and the heavier residue is similarly transferred to the third chamber, from the bottom of which the final residue free from metallic particles is withdrawn.—W. F. F.

Complex [sulphide] ores; Recovery process for the treatment of — and apparatus for same. C. J. Inglis, Hobart, Tasmania. Eng. Pat. 110,948, Nov. 10, 1916. (Appl. No. 16,166 of 1916.)

COMPLEX ores containing mixed sulphides, *e.g.*, of iron, zinc, and bismuth, are ground and mixed

with three times their weight of water. The mixture is delivered upwards through a central pipe and sprayed into a gas-tight chamber to which a mixture of hydrogen chloride and chlorine gases is continuously supplied. Reactions take place resulting in the solution of the metals and precipitation of sulphur, and to facilitate chemical action the chamber may be warmed by the introduction of steam. The outlet of the spray pipe may be regulated by a disc adjustable towards and away from the outlet, and the cover of the chamber may be water-sealed.—W. F. F.

Sulphides; Method of reducing — R. F. Bacon, Pittsburgh, Pa., Assignor to Metals Research Co., New York. U.S. Pat. 1,243,681, Oct. 23, 1917. Date of appl., Jan. 15, 1913.

THE sulphides of silver, mercury, arsenic, antimony, and platinum are treated with a hydrocarbon in a non-oxidising atmosphere at a relatively low temperature in such a way as to reduce the sulphides to metal quantitatively and convert the sulphur into hydrogen sulphide. For example, the hydrocarbon is allowed to drop on a heated mass of the precipitated sulphide at a suitable rate.

—T. H. B.

Zinc; Refining — G. C. Fricker, Luton, Eng. Pat. 110,970, Nov. 29, 1916. (Appl. No. 17,138 of 1916.)

THE distilling vessel and condensing vessel are placed in adjacent chambers which communicate by a controlled passage, so that the temperature of the condensing vessel is maintained slightly above the melting point of zinc. The surface of the impure molten zinc is covered by a thick layer of floating, inert, porous, refractory material, such as small pieces of foundry coke or fireclay, which retains lead vapour and other impurities, leaving pure zinc to pass over to the condensing vessel. In an alternative form, the separate condensing vessel may be omitted and the zinc vapour condensed in the distilling chamber itself. The wall dividing it from the heating chamber is not perforated and heating is effected by conduction through the wall.—W. F. F.

Electric welding or fusion-deposition of metals. The Quasi-Arc Co., Ltd., London, and L. Tweedale, Castleton, Lancs. Eng. Pat. 111,026, Mar. 9, 1917. (Appl. No. 3185 of 1917.)

IN the method of electric welding described in Eng. Pats. 1274 and 11,079 of 1912, and 13,538 of 1914, the work is carried on a table which is moved longitudinally or turned according to the joint to be made, and a rapid to-and-fro movement of about 0.25 in. amplitude is imparted to the work in a direction at right angles to the first movement. The latter movement causes the oscillation of the electrode over the line of the weld, and is caused by an eccentric shaft acting on a saddle mounted on the table. One or more electrodes are carried in suitable holders above the work and are stationary except for a feeding movement as the electrode burns, which is effected by gearing from the shaft which actuates the table. The feed for the electrode may be actuated by hand through a friction clutch so that the rate of feed may be varied as desired without affecting the other movements. The work is normally moved by a screw shaft and worm, and means are provided to allow for adjustment of the table by hand. A trip device may also be provided to stop the feed at any position of the table. In an alternative form the electrode may be moved to-and-fro with respect to the work instead of the work being moved.—W. F. F.

Gold and silver; Process for separation of — from minerals. R. Reyes, Mexico. U. S. Pat. 1,243,976, Oct. 23, 1917. Date of appl., Nov. 9, 1914.

THE finely divided mineral is added to a solution of sodium chloride or other suitable salt, and an electric current is passed through the solution, whereby the metals are deposited on the cathode. The mixture is agitated during the passage of the current by discharging gases upwards through it.

—T. H. B.

Chlorination of minerals; Apparatus for the —. R. Reyes, Mexico. U.S. Pat. 1,243,977, Oct. 22, 1917. Date of appl., Aug. 6, 1915.

A CHLORINATION tank consists of a receptacle for containing a solution to be electrolysed, the top of which has openings for ladders which are arranged to support electrodes in the receptacle at any desired height. One of the openings and ladder is large enough for use by a workman.

—T. H. B.

Tungsten trioxide; Process for extracting — from its ores. L. Rosenstein, San Francisco, and E. H. Simonds, Oakland, Cal. U.S. Pat. 1,244,082, Oct. 23, 1917. Date of appl., Sep. 27, 1916.

PULVERISED tungsten ore is mixed with water sodium carbonate and hydroxide are added, and the whole boiled; the mixture is filtered, excess of sodium carbonate removed by lime, and after separation of the calcium carbonate, a soluble barium compound is added, the mixture is boiled and the barium tungstate treated with hydrochloric acid to form tungsten trioxide.—T. H. B.

Molten metals; Treatment of — to increase their density. A. Rollason, Long Eaton, Derbyshire, Eng. Pat. 110,860, Mar. 2, 1917. (Appl. No. 3077 of 1917.)

THE molten metal, e.g., steel and its alloys, or rare metals and their alloys, containing combined or dissolved oxygen, is treated with 0.5—1.0% of metallic uranium, the proportion depending on the amount of oxygen or the desired density of the metal. The uranium combines with the oxygen and passes away with the slag.—W. F. F.

Concentrating alluvial ores or the like; Apparatus for —. J. F. Lobb, Wood Green, Middlesex, Eng. Pat. 110,977, Dec. 7, 1916. (Appl. No. 17,621 of 1916.)

Iron and steel; Process of changing the composition of —. H. Wade, London. From B. Ford, Philadelphia, U.S.A. Eng. Pat. 110,946, Nov. 9, 1916. (Appl. No. 16,093 of 1916.)

SEE U.S. Pat. 1,205,611 of 1916; this J., 1917, 88.

Furnace for smelting ores. C. J. Beaver and E. A. Claremont, Cheshire. U.S. Pat. 1,243,798, Oct. 23, 1917. Date of appl., Apr. 17, 1916.

SEE Eng. Pat. 6675 of 1915; this J., 1915, 1150.

Coating iron, steel, or other metals with metal; Process of —. E. Bernheim, Düsseldorf, Germany, Assignor to C. F. Burgess, Madison, Wis., and C. J. Kirk, New Castle, Pa. U.S. Pat. 1,244,414, Oct. 23, 1917. Date of appl., Mar. 20, 1914.

SEE Fr. Pat. 458,707 of 1913; this J., 1913, 1072.

Gas burners for metallurgical and other furnaces. Eng. Pat. 110,960. See IIA.

Method of making an insecticide [from smelter fumes]. U.S. Pat. 1,243,323. See XIXB.

XI.—ELECTRO-CHEMISTRY.

Furnace; A resistance [electric] —. F. Thornton, jun. Amer. Electrochem. Soc., Oct. 6, 1917. [Advance copy.] 12 pages.

EXPERIMENTS have been made on the heating of furnaces by resistors, placed either on the hearth or on a shelf around the walls. Such furnaces would be suitable for use in forging, heat-treating, tempering, and annealing steel, melting copper and brass, and firing ceramics and enamelled ware. Carbon does not form a satisfactory resistor material; it is necessary to use a very pure carbon, and owing to its negative temperature coefficient the temperature beneath the resistor bed becomes very high and the furnace lining suffers. Better results were obtained with silicon carbide blocks, bricks, or rods, and these were satisfactory with temperatures up to 1200° C., when resistors were provided in the roof of the furnace as well as on the hearth. Under these conditions there is an oxidising atmosphere in the furnace, but a reducing atmosphere may be obtained by spreading granular carbon over the resistor.—B. N.

Edison storage battery; Effect of lithium upon the capacity of the —. L. C. Turnock. Amer. Electrochem. Soc., Oct. 6, 1917. [Advance copy.] 8 pages. (See also this J., 1916, 1023.)

TESTS were made with an alkaline battery, in which lithium hydroxide was added to the 21% solution of potassium hydroxide in amounts up to 50 grms. per litre (a saturated solution of lithium hydroxide at about 24° C.). With increasing amounts of lithium hydroxide, an increased capacity up to a maximum of 12% was obtained over that given with pure potassium hydroxide, in spite of an increased resistance of 21% in the electrolyte.—B. N.

Synthetic gasoline by electrochemical means. Cherry. See IIA.

Resistance type furnace for melling brass. Bailly. See X.

Determination of copper as sulphide and by electrolysis. Hahn. See XXIII.

PATENTS.

Furnace; Electric —. I. R. Valentine, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,242,275, Oct. 9, 1917. Date of appl., May 12, 1917.

THE furnace is provided with a refractory division wall extending upwards from the base, part of the way to the upper wall, and a conductor, forming a stationary electrode, is located on the base, near one side of the wall. One or more movable electrodes, projecting through the roof of the container, co-operate with the stationary electrode to form an arc or arcs, and the space on the opposite side of the wall, adapted to receive material to be heated, is shielded by the wall from heat radiated directly from the arcs.—B. N.

Electrode and process of making the same. J. E. Thomsen, Assignor to The Joseph Dixon Crucible Co., Jersey City, N.J. U.S. Pat. 1,243,009, Oct. 16, 1917. Date of appl., Feb. 2, 1917.

A HARD, non-inflammable body is produced from a mixture of finely divided carbon particles of different sizes, 64%, tar, 33%, and a formaldehyde derivative, 3%, or cresols and phenols may be used in place of tar. The mixture is pressed into blocks, and calcined at a temperature above the decomposition point of the condensation product present.—B. N.

Galvanic cell. J. F. Sanders, Assignor to O. P. Coshov, Roseburg, Oreg. U.S. Pat. 1,243,111, Oct. 16, 1917. Date of appl., July 19, 1915.

A CATHODE for a galvanic cell is composed of a combination of palladium and rhodium.—B. N.

Electrolytic gas generators. 1. If. Levin, New York. Eng. Pat. 102,933, Oct. 27, 1916. (Appl. No. 15,357 of 1916.) Under Int. Conv., Dec. 26, 1915.

SEE U.S. Pat. 1,214,934 of 1917; this J., 1917, 391.

XII.—FATS; OILS; WAXES.

Castor oil used for lubricating aeroplane motors; Detection of foreign oils in —. C. Frabot. Ann. Chim. Analyt., 1917, 22, 217—223.

THE acetyl value is capable of indicating the presence of 1 to 2% of foreign oils in castor oil, but the other constants are of little value for the purpose. In the special case of castor oil adulterated with arachis oil the solidification point and the solubility in alcohol are the most sensitive tests (limit, 5%). For smaller amounts of arachis oil the turbidity temperature of the alcoholic solution may be determined. A solution of 1 vol. of pure castor oil in 95% alcohol remains clear when chilled below -20° C.; but in the presence of arachis oil the solution becomes turbid at temperatures ranging from +5° or +6° C. for 5% to -2° or -3° C. for 2% of arachis oil. An alcoholic solution of castor oil containing 1% of arachis oil becomes opalescent at -4° to -5° C. and turbid at -9° C. Foreign oils may be separated from castor oil by shaking 20 c.c. of the sample with 80 c.c. of petroleum spirit of b.pt. 35° to 70° C. in a stoppered graduated cylinder. After settling, the volume of the lower layer containing the castor oil will show an increase of about 11 to 12 c.c. if the oil is pure, or more if foreign oils are present. On evaporating 50 c.c. of the petroleum spirit layer a residue is left, which in the case of 12 samples of pure castor oil ranged from 8.35 to 8.70% of the original oil. Mixtures containing from 30 to 1% of arachis oil gave residues ranging from 38.61 to 10.04% and by deducting from these the average value for pure castor oil (8.52%), the results agreed closely with theory. The method also effects a concentration of the arachis oil, which facilitates the detection of arachidic acid by Bellier's method. For example, the petroleum spirit extract from castor oil containing 5% of arachis oil will contain 36.7% of that oil.—C. A. M.

Residues from the manufacture of alum and possible means of utilising them. Falcicola. See VII.

Candles. G. F. Powell and S. W. Bush, Bath. Eng. Pat. 110,579, Oct. 24, 1916. (Appl. No. 15,932 of 1916.)

A COLOURLESS varnish or paraffin wax stiffened

with a pulverulent combustible such as powdered precipitated cellulose, is applied to candles as an exterior coat to prevent guttering.—A. DE W.

Composition for cleansing, bleaching, decorticating, and for purifying and preserving food. Eng. Pat. 110,567. See VI.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Abietic acids; Optical isomerism of the —. F. Schulz. Chem.-Zeit., 1917, 41, 666—667. J. Chem. Soc., 1917, 112, i., 619.

ABIETIC acid may be prepared by extracting American colophony with dilute alcohol or by precipitating the alcoholic solution with hydrogen chloride, but whereas the alcoholic solution of the resin is dextro-rotatory, the solution becomes laevorotatory on addition of hydrogen chloride, so that the products above mentioned are probably not identical. When the resin is dissolved in boiling alcohol and dry hydrogen chloride passed into the cold solution, white crystals of abietic acid are obtained, the constants of which gradually alter on recrystallisation from acetone, from $[\alpha]_D = -77.9^\circ$ and m.pt. 161°C. to $[\alpha]_D = -98.8^\circ$, m.pt. 171°C. Further recrystallisation from acetone raises the m.pt. to 173°C. The molecular weight by titration is found to be 304. On exposure to air, the rotation alters owing to oxidation, and it changes also on heating at 200°C. American colophony, type H, extracted with dilute alcohol, yields an oil which gradually sets to a mass of crystals, from which by crystallisation from acetone a portion is obtained having $[\alpha]_D = -22^\circ$, whilst another part has $[\alpha]_D = +49^\circ$. An almost inactive fraction, $[\alpha]_D = +2.6^\circ$, is also obtained. On treatment with mineral acid, the rotation of the two last became negative. From technical resin oil the author has extracted an acid which he names oilsylvic acid (*Oelsylvinssäure*), m.pt. $171^\circ\text{—}173^\circ \text{C.}$, $[\alpha]_D = +53^\circ$, which does not alter in rotation when warmed with mineral acids, and in contradistinction to the abietic acid from colophony does not absorb oxygen from the air and does not turn yellow in light. The abietic acids can readily be esterified by boiling their alcoholic solutions with 30% of concentrated sulphuric acid for an hour.

PATENTS.

Lead pigments; Process of producing —. A. S. Ramage, Buffalo, N.Y., Assignor to International Color and Chemical Co., Inc., Detroit, Mich. U.S. Pat. 1,243,762, Oct. 23, 1917. Date of appl., Jan. 8, 1916.

LEAD pigments are produced by roasting a sulphide ore of lead to form lead sulphate and oxide, converting the lead sulphate into carbonate by treating with an aqueous solution of a carbonate, dissolving the mixed lead carbonate and oxide in caustic alkali solution, and re-precipitating lead carbonate by carbon dioxide. The lead carbonate is finally converted into a basic salt by treatment with caustic alkali.—A. DE W.

Calcimine [dislemper] and process of making same. R. W. Cornelison, Assignor to The Cott-A-Lap Co., Somerville, N.J. U.S. Pat. 1,244,033, Oct. 23, 1917. Date of appl., Mar. 27, 1914.

A PREPARED calcimine contains, in addition to solid ingredients the bulk of which is insoluble in water, a lake-forming colouring-matter and a precipitant for it, and an effervescent material to assist disintegration of the product when brought into contact with water.—A. DE W.

Phosphorescent colours; Art of making —. R. F. Langer, San Francisco, Cal. U.S. Pat. 1,244,058, Oct. 23, 1917. Date of appl., Mar. 15, 1916.

A BASIC composition consisting of lithium carbonate, sulphur, barium carbonate, water, and alcohol is first applied to the surface, followed by a second composition of manganese sulphite, strontium carbonate, sodium chloride, sulphur, anhydrous sodium carbonate, and ethyl alcohol.—A. DE W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation tests. L. E. Campbell. Bull. Dep. Agric., Ceylon, No. 32. India Rubber J., 1917, 54, 725—727. (Cf. this J., 1917, 92, 604.)

EXPERIMENTS were made to ascertain the effect of dilution of the latex upon the vulcanisation and mechanical properties of the rubber. The apparent difference in the rates of coagulation appears to depend not so much upon the rate at which the emulsoid phase is destroyed as upon the rate at which the rubber particles cohere. Generally speaking the results of the experiments are inconclusive. The effect of dilution on the rate of cure is not very marked. All samples from undiluted or slightly diluted latex gave good mechanical tests; in some cases those from greatly diluted latex gave distinctly low results. The results were, however, too irregular to allow definite conclusions to be drawn. The diminution effected by dilution in the quantities of mineral constituents, protein, and resin in the rubber, may, however, be of importance.—E. W. L.

PATENT.

Rubber latices; Process for the treatment [coagulation] of —. C. A. Hcken and St. V. B. Down, Singapore. Eng. Pat. 110,560, Sept. 20, 1916. (Appl. No. 13,650 of 1916.)

PRIOR to coagulation with the mixture of alcohol and petroleum benzene described in Eng. Pat. 8487 of 1915 (this J., 1916, 854), latex is mixed with glycerin, $\frac{1}{2}$ oz. per gallon, or with a mixture of glycerin, 1; alcohol, 4; and water, 5 parts, in the proportion of $\frac{1}{2}$ oz. per gallon. When, after 8 hours, a spongy coagulum is formed, 1 oz. (per lb. of rubber present) of the coagulating mixture is injected into the container. On standing overnight the clot discharges much of its serum, and it is then pressed or mangled and finished as desired. Other polyhydric alcohols or their derivatives or glycerol esters may be used in place of glycerin.—E. W. L.

XV.—LEATHER; BONE; HORN; GLUE.

PATENT.

Plastic masses from casein or other swelling substances; Apparatus for the manufacture of —. R. Weiss, Hamburg, Germany. Eng. Pat. 107,769, July 5, 1917. (Appl. No. 9726 of 1917.) Under Int. Conv., July 7, 1916.

WITHIN the nozzle of a forcing machine, or bar press, for preparing plastic materials in the form of bars, thin sieve-plates, with fine holes, and each supported by a thicker plate with large holes, are arranged one in front of the other, with the object of eliminating enclosed air-bells, and producing a perfectly solid bar.—E. W. L.

XVI.—SOILS; FERTILISERS.

Soil acidity; Nitrification as a measure of the availability of different forms of calcium carbonate when employed as correctors of —. P. S. Burgess. Soil Sci., 1917, 4, 327—336.

CALCIUM carbonate, in the forms of soft coral

limestone and coral sand, was applied to a sample of an acid soil from Hawaii in sufficient quantity to effect neutralisation, and the mixtures were incubated and the nitrate present determined every two weeks for twenty weeks. Similar mixtures with addition of dried blood and of ammonium sulphate were included in the experiment. The results showed that one form of calcium carbonate was as effective as the other on the soil alone. When a fertiliser was added, the finely ground coral limestone was one and a half times as effective as the best grade of coral sand. In the soil alone, larger quantities of nitrogen were converted into nitrate from blood than from ammonium sulphate, but in the presence of either form of calcium carbonate the reverse was the case.—J. H. J.

Ammonification; Further studies of the nature of — K. Miyake. *Soil Sci.*, 1917, 4, 321—325.

SPECIMENS of various soils were mixed with leucine and with tyrosine and incubated at 30° C. for 16 days, the ammoniacal nitrogen produced being determined at intervals. In the case of leucine, this amounted to about 80% of the possible, and in the case of tyrosine, 40—80%. The process was found to be an autocatalytic reaction, proceeding in accordance with the author's equation previously given (see this J., 1917, 227).—J. H. J.

Phosphorus; Determination of soil — C. O. Rost. *Soil Sci.*, 1917, 4, 295—311.

A COMPARISON was made of four methods for the determination of phosphorus in soil, namely, fusion with sodium carbonate, extraction with *aqua regia*, ignition and extraction with nitric acid, and evaporation with hydrofluoric acid, together with two modifications of the last. It was found that the fusion method gave accurate results, only traces of phosphate remaining in the separated silica, and evaporation with magnesium nitrate before ignition was unnecessary, as was also an initial precipitation of the phosphate along with iron and aluminium hydroxides. In the method of double extraction with *aqua regia* with ignition in between, there was no loss from volatility of phosphorus, but a large amount of the phosphate was left undissolved in the residue. The method of extraction with nitric acid after ignition, gave complete extraction in one case but not in another. The hydrofluoric acid method was found to leave a considerable amount of phosphate in the residue, owing to the formation of difficultly soluble iron and aluminium phosphates. A modification of the method, in which the soil is evaporated with nitric acid previous to ignition, gave still lower results, due to a considerable amount of phosphate being contained in the filtrate from the ammonium molybdate precipitate. The author found that this method could be rendered accurate when modified as follows: 1 gm. of soil is ignited at a dull red heat, and when cold, 10 c.c. of distilled water, 10 c.c. of nitric acid, and 5 c.c. of hydrofluoric acid are added, the mixture is well stirred and is evaporated to a volume of about 5 c.c., when a further 5 c.c. of hydrofluoric acid is added and the mixture evaporated to dryness. Then the residue is evaporated two or three times with small quantities of nitric acid, after which it is dried at 110° C. for an hour, taken up in 3 c.c. of nitric acid and 7 c.c. of water, and the liquid boiled and filtered. The filtrate is precipitated with ammonium molybdate, and the precipitate redissolved and finally converted into magnesium pyrophosphate. It was found that the titanium oxide present in soils did not affect the determination of phosphate.—J. H. J.

Phosphorus; Production of available — from rock phosphate by composting with sulphur and manure. P. E. Brown and H. W. Warner. *Soil Sci.*, 1917, 4, 269—282.

AN investigation was conducted to determine whether mineral phosphates would be decomposed by sulphuric acid produced by bacterial action in manure heaps. Preliminary experiments were made to determine if horse and cow manures and compost contained the necessary sulphur-oxidising bacteria, and it was found that they oxidised as much sulphur to sulphuric acid as rich loam soil. These manures were then mixed with finely ground rock phosphate containing about 12% of total phosphorus and with precipitated sulphur, and were kept at the temperature of the laboratory and analysed periodically during 15 weeks. In the manures mixed with sulphur there was a slight increase in the amount of available phosphorus, but in those with rock phosphate there was a distinct depression in the amount. In presence of both sulphur and rock phosphate there was a continual increase in the available phosphorus throughout the whole period with each manure, the increase amounting to 24% of the total phosphorus. This increase was greater when the materials were intimately mixed with the manures than when they were added in layers.—J. H. J.

Phosphates; Vegetation experiments on the availability of treated — J. G. Lipman and H. C. McLean. *Soil Sci.*, 1917, 4, 337—343.

POT culture experiments on several crops were made with rock phosphate which had been composted with sulphur, in order to compare its availability for plant use with that of acid phosphate (superphosphate). It was found that the treated phosphate was about as available as the superphosphate. Untreated rock phosphate had little effect in promoting growth except in the case of buckwheat, which utilised this form of phosphate equally as well as the other two forms.

—J. H. J.

Basic slag; Chemical composition of — C. van R. Janssens. *Versl. Landbouwk. Onderzoek. Rijklandsproefstat.*, No. 20, 26—33. *Bull. Agric. Intell.*, 1917, 8, 1105.

SINCE the beginning of the war two types of basic slag have been put on the Dutch market, one with a low content of phosphate, the other with a high content. The average analyses of these two types were respectively as follow: phosphoric anhydride, 7—8% and 15—19%, silica, 13—17% and 6—14%, alumina, 2—3% and 1—4%, total iron, 28—32% and 11—18%, manganese oxides, 4—5% and 6—13%, total lime, 37—43% and 46—52%, magnesia 3—4% and 1—3%. The high standard slag is equal to normal slag, but this is not the case with the low standard slag, since the high content of iron causes formation in the soil of iron phosphate, which is useless for fertilising.

—J. H. J.

Calcium cyanamide; Determination of the cyanamide nitrogen in — A. D. Berkaut, R. D. Hendricksz, and G. Wind. *Versl. Landbouwk. Onderz. Rijklandsproefstat.*, 1917, No. 20, 43—51. *Bull. Agric. Intell.*, 1917, 8, 1105—1106.

A SOLUTION of calcium cyanamide is prepared by mixing 2 grms. of the finely ground substance with small quantities of water at a time, and decanting into a litre flask until nearly full. The flask is then shaken vigorously for an hour, the contents made up to the mark and filtered. 100 c.c. of the filtrate is measured into a 200 c.c. flask, neutralised with nitric acid (10%) and 5 c.c. of ammonia (2.5%) added. N/10 silver nitrate is added from a burette with continual shaking until the precipitation of the cyanamide is complete. The contents of the flask are then made up to the mark,

shaken, and filtered through a double filter. The excess of silver nitrate is determined by Volhard's method. Alternatively the determination may be completed by collecting the precipitate of silver cyanamide quantitatively, washing, and submitting the filter and contents to Kjeldahl's process.

—J. H. J.

Manures and foods: Growth of international trade in —. J. Hendrick. Trans. Highland and Agric. Soc. Scotland, 1917. [Reprint.] 36 pages.

THE author deals chiefly with the growth in the volume of trade in manures, with some remarks on food. International trade in manures began about 1810, when Peruvian guano was first exported to Europe, chiefly to Britain. Guano continued to be the imported manure in greatest use until 1880, by which time the deposits had been mostly worked out. Since 1880 other countries have surpassed Britain in the importation of artificial manures. *Nitrogenous manures.* The annual export of sodium nitrate from Chili has increased from 3000 to 3,000,000 tons between 1886 and 1916. In Britain the net imports have risen from 99,000 metric tons to 143,000 metric tons between 1905 and 1913. The production of ammonium sulphate has developed with the gas industry. In 1870 Britain produced about 40,000 tons and in 1913 over 400,000 tons, of which only a quarter was used at home, the rest being exported. On the other hand, Germany, Belgium, and the United States imported more than they produced. The world's production has risen from nearly half a million tons in 1900 to one and a half million tons in 1913. The production of synthetic nitrogenous manures has increased very rapidly also during the few years it has been in operation. Calcium cyanamide has increased from 26,000 metric tons in 1910 to 156,000 metric tons in 1913, none of which was produced in Britain. Calcium nitrate has been produced in Norway only; in 1905, 127 metric tons was made, whereas in 1913, 73,000 metric tons was made, most of which was exported to Germany. In the latter year Germany imported 78,000 metric tons of all the synthetic manures, the United States 14,000 metric tons, and France 10,000 metric tons, while Norway exported over 100,000 metric tons, compared with 25,000 metric tons in 1911. *Phosphoric manures.* Bones were earliest used. India is the largest exporter with over 100,000 metric tons in 1913. Britain uses about 100,000 tons a year, of which 40,000 tons is imported. The world's production of mineral phosphates in 1903 was 2½ million metric tons, and in 1913 nearly 7 million metric tons, of which the production in North Africa formed 350,000 tons and 2½ million respectively. The imports of mineral phosphates into Britain during the same period increased only slightly. Most mineral phosphates are converted into superphosphate, of which Britain produced 620,000 metric tons in 1900 and 820,000 metric tons in 1913. France nearly one million and nearly two million metric tons respectively, and Germany 600,000 and 1,800,000 metric tons. The use of basic slag has increased along with the use of the basic process of steel making, from 10,000 tons in 1880 to 1½ million tons in 1900. Since 1900, the production in Britain has increased from 120,000 tons to 400,000 tons, of which 100,000 tons is exported; that of Belgium from 100,000 to 650,000 tons, of which over 500,000 tons is exported; and that of Germany from 1 million to 2½ million tons, of which only a quarter of a million is exported. *Potash manures.* The German deposits have formed almost the sole source of potash for all purposes, the output growing from 2200 tons in 1861 to over 11 million tons in 1913, mainly due

to an increase in the agricultural use of potash, this being 42% of the output in 1880 and nearly 90% in 1910. Germany uses practically as much potash for agriculture as all other countries put together. In Britain the consumption increased rapidly between 1900 and 1913, Scotland using the largest amount per acre of arable land. *Crop production.* It was reasonable to suppose that those countries which were rapidly increasing their consumption of fertilisers were also increasing the crops produced, and this was found to be the case. Crop production in Germany, in the case of wheat, averaged 13.2 million tons in 1879—83 and 26.9 million tons in 1909—13; and the average per acre was 10.24 centals and 17.86 centals, respectively. In England the yield of wheat per acre per annum was 29.5 bushels in 1885—9 and 31.2 bushels in 1909—13. In Germany the corresponding figures were 19.8 and 31.6. The figures for potatoes were: England, 5.9 and 6.2 tons; Germany, 3.4 and 5.4 tons. Before the war Germany and Austria produced twice as much wheat and rye as France and Britain, more than twice as much of other cereals, and more than three times as much potatoes. Calculated per head of population, these amounts become:—

	Central Powers.	Britain.	France.
	lb.	lb.	lb.
Wheat and rye	460	77	570
Other cereals	440	210	330
Potatoes	1200	320	760

—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Cane sugars; Filtration of syrups prepared from raw — in the refinery. H. Pellet. Bull. Assoc. Chim. Sucr., 1917, 35, 183—186.

IT has been suggested by Manoury (J. Fabricants de Sucre, 1916, June 21) that difficulties of filtration in the refining of raw cane sugars might be avoided by first raising the purity of the sugars to 99%. The author states that in a large Parisian refinery it is now the practice to bring all raw cane sugars to 99% by a preliminary washing, but the difficulty of filtration still remains and varies considerably in different cases. It is due to particles of bagasse, to gummy matters, and also probably to small quantities of silica, part of which is in a colloidal form. The amount of these impurities present in a raw sugar depends on the method of manufacture. Cane mills which by repeated crushings extract a very high proportion of sugar, e.g., 94—95% or even more, necessarily extract a large amount of these impurities also. Ordinary defecation of the raw cane juice, with or without sulphitation, does not eliminate them, though carbonatation does. Their presence renders the centrifuging of raw cane sugars a more protracted operation than that of beet sugars. Even when brought to a purity of 99% by washing, raw cane sugars do not yield clear solutions, and in the refinery they require a much greater filtering surface than beet sugars, in some cases three times as great.—J. H. L.

Sugar; Action of basic lead acetate on invert —. H. Pellet. Bull. Assoc. Chim. Sucr., 1917, 35, 186—194.

THE author suggests that the conflicting conclusions published on the one hand by Davis (this J., 1916, 203) and on the other by various chemists (see, e.g., Deerr, this J., 1916, 1075), respecting

the precipitation of reducing sugars by basic lead acetate, are due to a difference in the composition of the liquids studied. In liquids, such as molasses, which contain a considerable amount of salts, the lead precipitate invariably carries down some reducing sugar. This is not necessarily the case with liquids containing organic matters, but almost or entirely free from salts, as in Parkin's experiments with sugar solutions containing tannin (see Davis, *loc. cit.*). The plant extracts studied by Davis would probably belong to the second class.—J. H. L.

Arsenic in glucose [; *Determination of* —]. A. Kling. *Ann. Falsif.*, 1917, 10, 438—450.

THE author made a comparative study of the accuracy of three methods of determining small quantities of arsenic (in solutions free from organic matter), viz., the Marsh-Berzelius, the Gutzeit, and a so-called diaphanometric method in which the arsenic is reduced to the elementary state by hypophosphorous acid in presence of sulphuric acid and estimated from the cloudiness of the liquid in comparison with a series of test solutions of known arsenic-content treated in the same way at the same time. The possible error of all three methods was found to be of the same order, about one-tenth of the amount of arsenic determined, but the Gutzeit method is not considered so trustworthy as the others for quantitative purposes. The diaphanometric method is somewhat more expeditious than the Marsh-Berzelius method; it is rendered inexact by the presence of traces of nitrates or nitrites. From solutions containing sugars, traces of arsenic can, after oxidation with bromine, be completely precipitated by entrainment in precipitates of ammonium magnesium phosphate formed in the solutions. Modifying a procedure described by Vuaffart (*Ann. Falsif.*, 1916, 272), the author applied this method to commercial glucoses; the phosphate precipitate was dissolved in nitric acid, all traces of the latter were then eliminated by evaporation with sulphuric acid, and the sulphuric acid solution was used for the determination of arsenic by the diaphanometric method. Experiments described indicate that traces of arsenic in beer-wort are not eliminated to any extent during fermentation or fining of the fermented beer.—J. H. L.

Potatoes; Utilisation of rotten — in the manufacture of starch. Ducomet and A. C. Girard. *Comptes rend. l'Acad. d'Agric. de France*, 1917, 3, 716—719. *Bull. Agric. Intell.*, 1917, 8, 1191.

SPOILED potatoes are suitable for starch manufacture provided decomposition has not gone very far. According to Ducomet's observations, even when the tubers are in a deliquescent state, the starch is still undecomposed, and only at a later stage does it undergo liquefaction. It is therefore advisable to collect all potatoes attacked by damp rot, whether caused by frost, or mildew or other organisms, and extract the starch, which after proper sterilisation is fit for consumption by man or animals. The period during which spoiled potatoes can be kept before treatment may be considerably prolonged by covering them with water and changing this from time to time. It is pointed out by Girard that about 75% of the nitrogen and 90% of the potash contained in the tubers is carried off in the water in which they are washed. On the farm this water might be absorbed by manure heaps or even by the soil, to utilise the valuable constituents. If it is first brought to the boiling point, about half of the contained nitrogen is precipitated as protein, which after deposition could be fed directly to stock.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Behaviour of — towards different sugars at various concentrations, and the influence of addition of alanine on fermentation. E. Abderhalden. *Fermentforsch.*, 1916, 1, 229. *Woch. Brau.*, 1917, 34, 138.

THE course of fermentation was studied by the aid of a registering balance designed to record automatically the loss of weight due to evolution of gas. In sucrose solutions containing 10—30 grms. in 250 c.c., fermented at 30° C. by equal quantities of beer yeast, the rate of production of carbon dioxide was found to be independent of the initial concentration of sugar, but this was not the case when yeast juice or dried yeast was used. Addition of alanine, up to a certain limit of concentration, accelerated fermentation by living yeast. The rate of fermentation of dextrose was somewhat slower than that of laevulose, and was not independent of the concentration of sugar. Fermentations effected by pressed yeast juice or by dried yeast, were characterised by a very slow initial rate which afterwards increased rapidly.—J. H. L.

Enzymes; Chemical composition and formation of —. XIII. Alterations in the amount of enzyme in kephir grains and in *B. lactis acid.* H. Euler and E. Griese. *Z. physiol. Chem.*, 1917, 100, 59—68. *J. Chem. Soc.*, 1917, 112, i., 679—680. (Compare Euler and Cramér, *this J.*, 1914, 97, 272.)

KEPHIR grains which have been grown previously once or twice in a mixture of whey and galactose, with and without the addition of phosphates, contain a larger quantity of enzyme in relation to dry weight than is contained in the original material. In other words, the same weight of kephir grains produces a more rapid and a greater evolution of carbon dioxide after propagation in a suitable medium than in the original condition. When the lactic acid bacillus is similarly grown in successive fresh quantities of a medium of whey containing 4% of galactose, the rate of formation of lactic acid by a standard number of bacilli is increased. If, however, 6% of sodium dihydrogen or disodium hydrogen phosphate is also present in the medium, the formation of the lactic acid soon diminishes, and, instead, an increasing quantity of carbon dioxide is produced. By suitable preliminary treatment, therefore, it is possible to stimulate the production of one or other of the enzymes in the living cell.

Glycolysis. G. G. Wilenko. *Z. physiol. Chem.*, 1917, 100, 255—263. *J. Chem. Soc.*, 1917, 112, i., 680.

THE fermentation of dextrose by yeast occurs without the formation of carbon dioxide when the hydroxyl-ion concentration of the medium is maintained within certain limits. This can be effected by adding a buffer-mixture of sodium dihydrogen and disodium hydrogen phosphates in the proportion of one of the former to ten or more (depending on the kind of yeast) of the latter. The same result can be achieved without phosphates by the simple addition of a slight excess of N/1 sodium hydroxide solution. If the yeast at the end of an experiment is collected and treated with fresh dextrose solution, ordinary fermentation with evolution of carbon dioxide ensues, indicating that in the original experiment the hydroxyl ions are associated with the dextrose or its degradation products rather than directly with the enzyme.

Alcoholic fermentation at different concentrations of hydroxyl ion. H. Euler and K. Haldin. Z. physiol. Chem., 1917, 100, 69—73. J. Chem. Soc., 1917, 112, i., 680. (Compare Wilenko, preceding abstract.)

THE fermentation of dextrose by yeast proceeds even in the presence of alkalinity equivalent to *N*/20-ammonium hydroxide solution. If an adequate proportion of ammonium phosphate is also added, the production of carbon dioxide is greatly diminished, although the amount of dextrose fermented may be as great as it was before the addition of the ammonium phosphate, similar conditions of time, temperature, and concentration being maintained.

Yeast; Increase of dry weight of — when urea is used as the source of nitrogen. T. Bokorny. Biochem. Zeits., 1917, 82, 359—390. J. Chem. Soc., 1917, 112, i., 680.

A NUMBER of experiments are quoted which show that a considerable growth of yeast (as measured by increase in dry weight) can take place when the organism is grown on urine containing sugar. The urea, and not hippuric acid, acts as the source of nitrogen. The growth is especially vigorous in presence of air.

Saccharophosphatase of yeasts and the fermentation of sucrose-phosphoric acid. K. Djenab and C. Neuberg. Biochem. Zeits., 1917, 82, 391—411. J. Chem. Soc., 1917, 112, i., 680—681.

YEASTS contain an enzyme "saccharophosphatase," which can hydrolyse the salts of synthetic sucrose-phosphoric acids, prepared originally by Neuberg and Pollak (hesperonal). Scission of inorganic phosphate takes place. The enzyme is found in both top and bottom yeasts. It is to be distinguished from the already known hexophosphatase in that the latter acts only in yeast juices separated from the living cell, whereas the new saccharophosphatase will act in the living cell, and produce alcoholic fermentation of the synthetic sucrose-phosphate. It is also insensitive to the action of antiseptics, both when fresh yeast is used or maceration juice. It acts between the temperatures of 22° and 37° C. and in neutral, alkaline, and weakly acid (acetic acid) solutions. The soluble sodium salts of the synthetic sucrose-phosphoric acid can be hydrolysed to the extent of 67% by fresh yeast and 45% by maceration juice.

Sugar fermentation and assimilation of sugar; Relationship between —. T. Bokorny. Allg. Braun- u. Hopfen-Zeit., 1917, 57, 447—480. J. Chem. Soc., 1917, 112, i., 681—682.

THE influence of fractional addition of sugar, of nitrogen nutriment, and of addition of alkali are considered. The increase in dry substance in the fermenting yeast is regarded as a criterion of the extent of assimilation. Under unfavourable conditions a loss in weight occurs, but, in better circumstances, the extent of assimilation exceeds that recorded by Pasteur, according to whom about 1% of the sugar is assimilated. Repeated addition of sugar without alteration in the total quantity appears beneficial. Urea, even in pure aqueous solution, is a more suitable source of nitrogen than ammonia; apparently this is more effective when gradually formed than when applied in the preformed state. Similarly, assimilation is favoured by the substitution of sucrose for dextrose. Assimilation is promoted by free potassium hydroxide at certain concentrations, preferably at about 0.01%. Previous experiments on the application of dextrose as a food for moulds and for the formation of starch in *Spirogyra* are discussed; in the latter instance, the influence of light and of access of oxygen is particularly noticeable.

Beer; Sterilisation of —. P. Petit. Brasserie et Malterie, 1917, 7, 1—4, 17—20, 33—36.

AMONG the numerous processes which have been proposed for sterilising beer, to render it stable indefinitely, the only one extensively used hitherto is pasteurisation. This process, however, has certain disadvantages; it is liable to affect the flavour of beers, and to give rise to turbidity, which sometimes appears only after a few days. The turbidity might perhaps be prevented by a peptonising treatment such as Wallerstein's (see this J., 1916, 1170), but the practical difficulties associated with pasteurisation, especially as applied to beer in bulk, render unlikely any further developments of importance in this method of sterilising beer. Relatively little attention has been devoted, within recent years, to the possibility of sterilising beer by filtration. Filters of the Chamberland type are impracticable, on account of their very limited capacity and because they deprive beer of certain valuable colloidal constituents. Ordinary pulp filters, on the other hand, do not retain bacteria. Between these extreme types, however, there are possibilities which were explored to some extent by Thevenot, who experimented with infusorial earth and pipe-clay as filtering media. Recently a sterilising filter of this type, with batteries of filtering tubes, has been installed in a number of American breweries and appears to have given satisfaction. The largest models have a capacity of about 750 galls. per hour. Information is at present lacking as to whether these filters are suitable for European beers which are required to show a stable creamy head. This character is not possessed in the same degree by American beers; it depends on the presence of certain colloidal matters, the retention of which by the filter would be a serious disadvantage. The bottling of sterilised beer, without infection, demands a standard of biological cleanliness, as regards pipes, racking apparatus, and bottles, which has not hitherto been attained in practice. Some of the practical problems involved are discussed by the author. The sterilising filter referred to above is combined with an automatic plant for the cleansing and sterilising of bottles, which appears to represent a considerable improvement on existing systems.—J. H. L.

Italian wines; Application of Halphen's ratio to —. F. Scurti and E. Rolando. Annali Chim. Appl., 1917, 8, 47—77.

HALPHEN (Bull. Soc. Chim., 1906, 35, 879) based a test of the purity of wines on the ratio between the acidity and the alcoholic strength. Applying this test to typical Italian wines, the authors conclude that in the case of acid wines 25% of water may be added without interfering with the ratio. The test is of no value as an absolute criterion of purity, although it may be of use as a supplementary test in deciding whether a wine of unknown origin is genuine.—C. A. M.

[Distillers'] mashes; Saccharification of — by means of malt. A. Vasseux. Bull. Assoc. Chim. Sucr., 1917, 35, 237—238.

THE following method of saccharifying distillers' mashes by means of a small proportion of malt, has given good results, and is recommended to distillers who wish to abandon saccharification by means of acid in order to produce spent grains suitable for feeding purposes. The raw grain is cooked as usual and transferred hot into small closed vats similar to those used in the amylo-process (see this J., 1914, 562). When full, the vats are cooled, and sterilised air is introduced meanwhile. When the temperature has fallen to 55° C. a mash of green or dried malt (representing 3—5% of the charge of grain) is added, and the charge is kept in motion, without further cooling,

for an hour, within which period saccharification is complete. There is little risk of infection, but antiseptics may be used if necessary. Cooling is then resumed and the yeast is introduced when the temperature has fallen to 35° C. At 24° C. cooling is stopped, and after fermentation has become vigorous, the charge is transferred to open vats in which the fermentation is completed as usual.

—J. H. L.

Starch; Formation of—by mould fungi. F. Boas. *Biochem. Zeits.*, 1917, 78, 308. *Woch. Brau.*, 1917, 34, 47.

In experiments with *Aspergillus niger* and *Penicillium glaucum*, cultivated in solutions of sucrose, dextrose, levulose, or dextrin, containing ammonium salts, the liquids after some time acquired the property of yielding with iodine a blue coloration which vanished on warming. A substance coloured blue by iodine was also observed in the mycelial cell-walls of the moulds. Under the influence of diastase the liquids lost their power of reacting with iodine. Alcohol precipitated the starch-like substance from solution in a flocculent form. The formation of this substance is attributed to the influence of the free acidity liberated in consequence of the assimilation of the nitrogen of the ammonium salts by the moulds, for similar results were obtained also in sugar solutions, and in beer wort, treated with free tartaric, phosphoric, or sulphuric acid (see also this J., 1917, 1024).

PATENT.

Fermented beverage; Non-intoxicating—and process of making the same. C. A. Nowak, St. Louis, Mo. U.S. Pat. 1,243,440, Oct. 16, 1917. Date of appl., Mar. 22, 1915. Renewed Mar. 15, 1917.

Wort of approximately 25°–35° Balling, relatively poor in readily fermentable carbohydrates, is fermented at a fairly high temperature, e.g., 23°–35° C., by yeast in presence of acid-forming bacteria. For instance, the fermentation, lasting 6–12 hours, may be effected by means of vinegar ferment. The product may be diluted with hopped water. —J. H. L.

XIXA.—FOODS.

Margarines and butter substitutes; Nutritive value of—with reference to their content of the fat-soluble accessory growth substance. W. D. Halliburton and J. C. Drummond. *J. Physiol.*, 1917, 51, 235–251. *J. Chem. Soc.*, 1917, 112, i, 673.

The fat-soluble accessory growth substance of beef-fat and “oleo-oil” is present in margarines prepared on such a basis. Such margarines are nutritively equivalent to butter. Coconut oil, cotton-seed oil, arachis oil, and hydrogenated vegetable oils contain little or none of this accessory substance. Margarines from these, and nut butters prepared from crushed nuts, are not equal to butter in nutritive value. Lard substitutes from vegetable oils are equal to lard in nutritive value, both alike being destitute of the fat-soluble accessory substance.

Cottonseed products; Methods for approximating the relative toxicity of—. F. E. Carruth. *J. Biol. Chem.*, 1917, 32, 87–90.

Raw cottonseed kernels are highly toxic to animals owing to the fact that they contain about 0.6% of gossypol, a phenolic plant pigment. The meal obtained when the oil is extracted by hot pressing is usually not markedly toxic, since the gossypol is readily changed by oxidation into a substance which is insoluble in oil and ether; this oxidised product yields a blue coloration with alcoholic potassium hydroxide solution. In the cold pressing process most of the gossypol passes into the oil and is removed from the latter during refining operations. The presence of gossypol may be detected by treating a portion of the meal with a drop of concentrated sulphuric acid and immediately examining the mixture under the microscope; if numerous red areas appear where the acid touches the more or less broken up “glands,” the presence of toxic unchanged gossypol is indicated. To determine the quantity of gossypol present, a quantity of the meal sufficient to yield about 10 grms. of oil is extracted with ether, the ethereal solution evaporated, and the residue of oil, after filtration, is mixed with about 10% of its weight of aniline; the mixture is warmed on a water-bath and then set aside. If, after several days, no precipitate is formed, the meal may be considered to be free from gossypol. In the presence of gossypol, however, a yellow crystalline precipitate separates; this is collected, washed first with a mixture of ether and petroleum spirit (1:2), then with petroleum spirit, dried at 100° C., and weighed. The compound appears to be the dianiline salt of gossypol ($C_{30}H_{25}O_8$, $2C_6H_5NH_2$) and its weight is multiplied by 0.74 to obtain the quantity of gossypol. Cottonseed meals containing 0.24% or more of gossypol proved fatal to rats within 10 days; meals containing smaller quantities were injurious to the animals.—W. P. S.

Acorns and horse-chestnuts; Analytical examination of—. J. L. Baker and H. F. E. Hulton. *Analyst*, 1917, 42, 351–355. (See also this J., *Auld*, 1913, 173; *Rousset*, 1913, 243; *Goris*, 1917, 1107.)

The outer, green husk of fresh horse-chestnuts accounts for about 67% of their total weight. The nuts themselves consist of 22% of brown integument with 37% of water, and 78% of kernel (cotyledons) with 46.5% of water. Acorns as picked consist of 16% of shell with 43.7% of water and 84% of kernel with 46.4% of water. The accompanying table shows the percentage composition of samples of nuts and acorns prepared by peeling, grating, drying at 55° C., and then grinding finely in a handmill. The starch values were determined on the material after

	Peeled chestnuts.				Peeled acorns.	
	1.	2.	3.	4.	1.	2.
Moisture	2.6	3.5	1.85	2.4	1.45	3.32
Ash	2.9	2.8	2.45	2.77	2.25	2.70
Ether extract (oil) ..	6.1	5.0	7.1	7.2	5.0	4.7
Protein (N×6.25) ..	9.8	10.8	7.25	7.62	6.65	7.5
Reducing sugars as dextrose	3.6	9.1	3.29	1.6	4.9	8.18
Sucrose	8.1	11.1	7.27	17.5	1.9	0.1
Starch (Lintner)....	47.8	21.9	42.8	42.2	57.1	55.7

Cold water extract ..	34.9	48.4	32.56	36.2	13.2	17.24

extraction with ether and water. Those obtained by acid hydrolysis (Lintner) are too high, owing

to the formation of reducing sugar from a non-amylaceous substance, probably a constituent of the membranes which enclose the groups of starch granules. This substance, amounting to 13% or more of the dried chestnut kernels, swells to a jelly in water, and a dried sample of it gave the following results on analysis:—protein 12%, crude fibre 27.3%, ash 2%, pentosans 21.4%. The cold water extracts of the nuts and acorns contained besides sugars, 90% of the total mineral matters, widely varying proportions of the total protein (e.g., 30–70% for chestnuts and 20% for acorns), and no glucosides; those from the chestnuts contained about 16% of the total pentosans. Of the total matter extracted by cold water, 9.5–23% in the case of chestnuts, and 2.8–5.3% with acorns, could not be accounted for; similar instances of undetermined soluble matters occur in malt, cocoa, etc. Acorns were found to be almost entirely destitute of diastase, but chestnuts contained considerable amounts, of much greater saccharifying than liquefying power. Slight evidence of invertase activity was found in acorns before but not after germination. The starch granules of both chestnuts and acorns vary much in shape and size; they have well defined hila and inconspicuous striae. The average maximum diameter of the granules of acorn starch is 6–25 μ , and of horse chestnut starch 10–40 μ . Ground horse-chestnuts and acorns were boiled with 2% sulphuric acid for 3 hours under a reflux condenser, and the filtered and neutralised liquids were fermented with brewers' yeast. In both cases the yields of alcohol obtained amounted to about 27% of the dried peeled kernels, corresponding to 12% on the fresh horse-chestnuts or acorns (deprived of the outer green shell).—J. H. L.

Soy bean; Nutritive value of the—. A. L. Daniels and N. B. Nichols. J. Biol. Chem., 1917, 32, 91–102.

THE soy bean contains 36% of protein, 17.5% of fat, 12% of digestible carbohydrates, and 5.3% of mineral matter, as well as a sufficient quantity of water-soluble growth-promoting substance. Experiments on rats show that the bean is a valuable food, but that the mineral content needs supplementing by the addition of sodium chloride and calcium salts.—W. P. S.

Inulin; Enzymic degradation of— in the root of chicory. J. Wolff and B. Geslin. Comptes rend., 1917, 165, 651–653.

AFTER chicory roots have been gathered there occurs in the course of weeks a slow enzymic hydrolysis of inulin, with production of "inulides," corresponding to the dextrins from starch, and finally of levulose. The inulides are non-reducing, and are not coagulated by inulo-coagulase (see this J., 1916, 553); they are fermentable by yeast, though not to the same extent by all races. The enzyme of the root which effects their further degradation into sugar, appears to be identical with invertase, and is without action on inulin itself.—J. H. L.

Growth of international trade in manures and foods. Hendrick. See XVI.

Utilisation of rotten potatoes in the manufacture of starch. Ducomet and Girard. See XVII.

PATENTS.

Cheese: Manufacture of—. J. W. Trevan, London, and J. S. White, Spalding, Lines. Eng. Pat. 110,621, Nov. 2, 1916. (Appl. No. 15,695 of 1916.)

IN the manufacture of cheese, a non-poisonous soluble calcium salt, preferably the chloride, is added either to the milk direct, or mixed with

the rennet or pepsin. By this means curdling is effected at a lower temperature, and a smaller proportion of ferment is necessary. Good results may be obtained by the addition of 0.05 to 0.2% of calcium chloride to the milk.—L. A. C.

Margarine: Method and apparatus for crystallising—. M. Larsen and A. C. A. Zeuthen, Silkeborg, Denmark. Eng. Pat. 110,872, Mar. 20, 1917. (Appl. No. 4507 of 1917.)

THE apparatus consists of an emulsifying machine discharging the margarine emulsion continuously into a cooling trough provided with a shaft and paddles, which transmit the emulsion in contact with a stream of cooling water passing through the trough in the same or an opposite direction. During the passage through the trough the emulsion is thoroughly worked up with the water so that it is both cooled and washed. At the end of the trough the margarine is delivered to an inclined pipe in which is situated a worm and kneading device so that the product issues in a finished condition.—J. F. B.

Milk: Apparatus for use in pasteurising and like treatment of liquids such as—. A. C. A. Zeuthen and M. Larsen, Silkeborg, Denmark. Eng. Pat. 110,897, July 31, 1917. (Appl. No. 11,042 of 1917.)

APPARATUS having a vertical rotating drum-shaped member for stirring the liquid passing through in a continuous current is employed for pasteurising milk, the heat contained in the pasteurised milk being utilised for heating the cold liquid entering the apparatus. The rotating drum must always be filled with liquid, and for this object it is furnished with a neck, the upper end of which is bent over to form a depending collar, and an annular feeding funnel or chamber the inner wall of which projects freely up between the neck and collar, whereby the surplus liquid thrown out from the neck is prevented from entering the space between the rotating drum and the outer container but can be led through a pipe. By arranging this pipe at a suitable level and prolonging the lip of the depending collar, a liquid seal can be retained in the funnel so that the outer air cannot gain access to the space between the drum and container.—J. F. B.

Skimmed milk and vegetable-fat compounds; Apparatus for the production of—. J. F. Enz, Denmark, Wis. U.S. Pat. 1,213,275, Oct. 16, 1917. Date of appl., Apr. 9, 1917.

SKIMMED milk and a vegetable fat are conveyed through pipes from separate heating vessels to a mixing chamber from which the air is exhausted. The ends of the pipes in the mixing chamber are near together and are provided with sprayers adapted to mix the sprays of milk and melted oil.—W. P. S.

Bread manufacture. A. S. Wahl, Assignor to The Wahl Efficiency Institute, Chicago, Ill. U.S. Pat. 1,242,396, Oct. 9, 1917. Date of appl., Jan. 11, 1916.

READILY soluble, paste-like precipitated calcium sulphate, prepared as described in U.S. Pat. 1,156,448 of 1915 (this J., 1915, 1160), is added to the water used in making the dough.—W. P. S.

Shortening composition [for dough] and method of producing the same. Method of producing a shortening composition. H. A. Kohman, T. M. Godfrey, and L. H. Ashe, Pittsburgh, Pa., Assignors to Ward Baking Co., New York. U.S. Pats. (A) 1,242,883 and (B) 1,242,884, Oct. 9, 1917. Date of appl., Mar. 9, 1916.

(A) A FAT having m.pt. about 57° C. is mixed with a pulverulent carrier so as to produce a homo-

geneous finely-divided mixture. (B) Fat of m.pt. about 57° C. is heated at 200° C. and atomised into a closed chamber where the spray is absorbed by a pulverulent carrier; the carrier is kept in a state of agitation in the chamber until it has absorbed about one-fifth of its weight of fat.

—W. P. S.

Vegetables; Art of conserving fresh —. J. Schneible, Chicago, Ill. U.S. Pat. 1,242,728, Oct. 9, 1917. Date of appl., Aug. 8, 1917.

FRESH or green vegetables are immersed in 1% sodium bicarbonate solution at about 65° C.

—W. P. S.

Cocoa; Method of making so-called alkaliized —. W. C. Bladen, Jersey City, N.J. U.S. Pat. 1,243,244, Oct. 16, 1917. Date of appl., Nov. 24, 1916.

"COCOA liquor" is treated with gaseous ammonia under pressure in a closed vessel provided with rotating peripheral agitators.—W. P. S.

Milk; Substitute for — made from soya beans and arachis (pea) nuts. W. J. Melluish, Parkstone. U.S. Pat. 1,243,855, Oct. 23, 1917. Date of appl., Oct. 22, 1915.

SEE Eng. Pat. 9626 of 1915; this J., 1916, 903.

[*Electrical*] *apparatus for extracting dust from gases and vapours, applicable also for collecting particles of flour, cement, and other substances.* Eng. Pat. 110,774. See I.

Composition for cleansing, bleaching, decorticating, and for purifying and preserving food. Eng. Pat. 110,567. See VI.

XIXB.—WATER PURIFICATION ; SANITATION.

Fumigation as a disinfecting agency. C. T. Kingzett, H. F. Bottomley, and J. E. Brimley. Medical Press, Aug. 29, 1917. Chem. News, 1917, 116, 202–203.

A CHAMBER of 1018 cub. ft. capacity was constructed of brickwork lined with porcelain tiles, having a window opening from the outside and double doors. A broth culture of *B. typhosus* was absorbed on strips of filter paper which were placed on glass plates on the floor and 4 ft. and 6 ft. 4 in. above the floor. Some strips were tied up in three layers of fine muslin and placed in the same positions. Fumigation was carried out for 2 hrs. The strips were then transferred to broth tubes and incubated at 37° C. for 3 days. The fumigants used were formaldehyde generated from paraform tablets and from formalin by heat, and by the action of permanganate on formalin; the mixed vapours of formaldehyde and sulphur dioxide; and sulphur dioxide from a sulphur candle, alone and with aqueous vapour. It was found that formaldehyde had the same disinfectant action whether generated from paraform or formalin, and whether associated with aqueous vapour or not, but that the permanganate method of generation was less advantageous. The minimum found to be effective was the vapour from 17 grms. of paraform. Formaldehyde and sulphur dioxide mixed were effective when generated from 2.75 oz. of sulphur and 11 grms. of paraform, or from 2.5 oz. of sulphur and one fluid oz. of formalin, in an apparatus designed to burn the sulphur quickly and to generate sufficient heat to vaporise the paraform and formalin completely. Sulphur dioxide was found to be more efficient with aqueous vapour than when dry; the minimum required was the gas from 9 oz. of sulphur with 6 oz. of aqueous vapour. The experiments were made at different times of the year and at atmospheric temperatures ranging from 38° F. to 80° F. (3°–27° C.).—J. H. J.

Identification of chlorates in presence of hypochlorites. Wischo. See VII.

PATENTS.

Sewage; Method of treating —. W. H. Sawyer, Auburn, Me. U.S. Pat. 1,242,986, Oct. 16, 1917. Date of appl., Feb. 1, 1917.

THE suspended organic matter in sewage, except that of a fibrous nature, is reduced to a finely divided state, and when in this condition the fibrous matter and the water of suspension are removed. The fibrous matter is dried after removal.—J. H. J.

Boiler-water; Purifying —. H. Kriegsheim, Assignor to The Permutit Co., New York. U.S. Pat. 1,243,191, Oct. 16, 1917. Date of appl., Aug. 18, 1917.

HARD water is passed through a bed of base-exchanging silicate, the filtrate is mixed with oily condensation water, and an aluminium salt (e.g., the sulphate) added; the gelatinous hydrated aluminium oxide formed collects the oily globules.—J. H. J.

Insecticide [from smelter fumes]; Method of making an —. W. R. Macklind, Cleveland, and E. C. Holton, Olmsted Falls, Assignors to The Sherwin-Williams Co., Cleveland, Ohio. U.S. Pat. 1,243,323, Oct. 16, 1917. Date of appl., Mar. 13, 1915.

THE precipitated dust from smelter fumes is treated with an excess of a hydroxide, e.g., calcium hydroxide, to render the arsenic content available for use as an insecticide.—J. H. J.

Process for expressing liquid from materials [sewage sludge and fish refuse] containing the same. Eng. Pat. 110,601. See I.

XX.—ORGANIC PRODUCTS ; MEDICINAL SUBSTANCES ; ESSENTIAL OILS.

Morphine; Colorimetric methods for the estimation of very small quantities of —. A. Heiduschka and M. Faul. Arch. Pharm., 1917, 255, 172–191. J. Chem. Soc., 1917, 112, ii., 554.

1. *Georges and Gascard's iodic acid method* (this J., 1906, 779). The authors employ a modification of this method. Instead of using a Duboseq colorimeter, they prepare a scale of colours by diluting a faintly acid solution of morphine in about N/10-hydrochloric acid to a concentration of 1 in 1000 and then prepare from this a series of solutions of concentrations down to 1 in 10,000. Equal volumes (10 c.c.) of these solutions are treated with 5 c.c. of 5% iodic acid solution, and the yellow colorations are examined after about half a minute. The differences in colour are more pronounced in the more dilute solutions. Whilst morphine can be thus detected at a concentration of 1 in 12,500, quantitative observations can only be made at concentrations between 1 in 1500 and 1 in 5500. The method is rendered more sensitive if 1 c.c. of 10% aqueous ammonia is added about five minutes after the addition of the iodic acid. Morphine can thus be detected at a concentration of 1 in 18,500 and estimated at concentrations between 1 in 5000 and 1 in 16,500.

II. *Estimation with Marquis's reagent.* One c.c. of the morphine solutions prepared as above is evaporated in a small basin, the residue is treated with 1 c.c. of Marquis's reagent (2–3 drops of 40% formaldehyde solution, 3 c.c. of conc. sulphuric acid), and the violet solution is washed into the comparison tube with 4 c.c. of sulphuric acid. The colours are examined by transmitted light, since in reflected light an actual colour change from blue to bluish-brown renders the comparison untrustworthy. Morphine can thus be estimated

at concentrations between 1 in 1400 and 1 in 11,000, and, the dilution with the sulphuric acid being omitted, can be detected at a concentration of 1 in 25,000.

Two samples of ripe poppy capsules examined by these methods were found to contain 0.017 and 0.068% of morphine respectively; in neither case did the seeds contain morphine.

Mandelonitrile-glucoside, sambunigrin, and similar substances; Synthesis of—E. Fischer and M. Bergmann, Ber., 1917, 50, 1047—1069. J. Chem. Soc., 1917, 112, i., 657—659.

DRY, molten ethyl *dl*-mandelate was shaken with acetobromoglucose and silver oxide and so converted into a mixture of the ethyl tetra-acetylglucosidoamandelates. The mixture was converted into the unacetylated amides by means of methyl-alcoholic ammonia, and these were separated by crystallisation from a mixture of pyridine and ethyl acetate. A pyridine compound of *l*-mandelamideglucoside crystallised out, and this lost pyridine in a warm vacuum desiccator and on solution in water, leaving the pure amide as a glassy mass. The isomeride is also a viscous mass. Both were converted into crystalline tetra-acetates by treatment with acetic anhydride and pyridine. These were dehydrated to the nitriles by warming with phosphoryl chloride. The *l*-tetra-acetylglucosidomandelonitrile agreed with the tetra-acetate of natural *l*-mandelonitrileglucoside (see especially Power and Moore, this J., 1909, 258), whilst the *d*-isomeride coincides with the tetra-acetate of sambunigrin. These tetra-acetates are hydrolysed by means of warm methyl-alcoholic ammonia, but racemisation takes place and the product is *dl*-mandelonitrile-glucoside, identical with natural prulaurasin (see especially Caldwell and Courtauld, this J., 1907, 437). The mixture can be separated by crystallisation from a mixture of amyl alcohol and benzene (1:6). *d*-Mandelonitrile-glucoside, identical with sambunigrin (Bourquelot and Danjou, this J., 1905, 1123), crystallises out, and *l*-mandelonitrile-glucoside may be recovered from the mother liquor. Both glucosides are hydrolysed under the influence of emulsin, which is surprising, unless it is due to the rearrangement of one into the other isomeride by the enzyme.

Cantharidin. VI. Isocantharidin. VII. Reduction products of cantharic acid and hydrobromocantharic acid. J. Gadamer, Arch. Pharm., 1917, 255, 277—302. J. Chem. Soc., 1917, 112, i., 657—658. (Compare Rudolph, this J., 1917, 1027.)

THE formula of cantharidin advocated by Rudolph (*loc. cit.*) explains all the known facts except two: first, the formation of α -hemimellitic acid by the pyrogenic decomposition of barium cantharate, and secondly, the properties of isocantharidin and of isocantharidic acid. The second discrepancy is now removed by the author's discovery that the isocantharidin and isocantharidic acid of Anderlini and Ghira (this J., 1891, 944) are in reality acetylhydratocantharic anhydride, $C_{12}H_{14}O_5$, and acetylhydratocantharic acid, $C_{12}H_{16}O_6$, respectively.

In consequence of the genetic relationships recorded in this paper, the author re-names *d*-cantharic acid ($[\alpha]_D = +87.5^\circ$ to 90°) *l*-cantharic acid. When *l*-cantharic acid dissolved in rather more than the calculated quantity of sodium carbonate solution is reduced by Mannich's modification of the Paal-Skita method, only one product is formed, namely, *l*-dihydrocantharic acid, $C_{10}H_{14}O_4$, m. pt. 264° — $267^\circ C.$, $[\alpha]_D = -52.5^\circ$ in alcohol ($c=2$), and this is regarded by the author as evidence in favour of Rudolph's formula of cantharidin.

When an alkaline solution of *l*-cantharic acid

in aqueous sodium hydroxide is energetically reduced by hydrogen and palladium (on bone charcoal), *l*-dihydrocantharic acid and desoxy-cantharidin (or its hydrate, desoxycantharidic acid) are produced. The latter is optically inactive and agrees in all its properties with the desoxycantharidin obtained from the "dibromide" by Rudolph (*loc. cit.*). The author has obtained evidence which seems to indicate the existence of a second modification of desoxycantharidin, which is amorphous, sinters strongly at $100^\circ C.$, and is completely molten at about $115^\circ C.$

Veronal, acetanilide, salicylic acid, and phenacetin; Identification of—O. Tunmann, Apoth.-Zeit., 1917, 32, 289—292, 298—299. J. Chem. Soc., 1917, 112, ii., 551—553.

Veronal.—Zinc chloriodide solution is added to the sublimate from the veronal residue beneath a cover slip; numerous, generally small (up to 40μ long and 20μ wide), flat, tabular, and prismatic crystals are immediately formed, which vary in colour from pale grey to blackish-red. Acetanilide and salicylic acid do not react with zinc chloriodide. The veronal sublimate is dissolved by hydriodic acid, and crystals are slowly deposited at the edges of the solution; these are relatively large (up to 150μ long and 50μ wide), flat, red, or sometimes grey. With bromine-potassium bromide solution, a red colour is developed, due to a mixture of flesh-coloured and red needles and leaflets, which attain a length of 50 — 80μ , whilst, also, very small groups of yellow crystals are formed. The red crystals disappear in course of time, whilst the yellow are more stable. If the veronal sublimate is dissolved in ammoniacal copper solution and the latter allowed to evaporate, a mixture of pink to violet lamellae and coarse plates is obtained, which shines in polarised light.

Acetanilide.—Well-formed crystals are obtained by sublimation and recrystallisation from water. With hydriodic acid, reddish-brown drops are formed immediately, from which strongly dichroic (reddish-brown and pale yellow) crystals of iodoacetanilide separate after a few minutes. Bromoacetanilide is prepared by the addition of bromine-potassium bromide solution to the sublimate dissolved in hot water; a yellow solution results, from which, on addition of water, colourless needles separate, which are transformed partly into prismatic aggregates and partly into small, monoclinic crystals.

Salicylic acid.—Sublimation can be effected without decomposition of the acid into carbon dioxide and phenol. Better crystals are obtained after solution of the sublimate in water. They consist of prismatic rodlets and coarse, generally rectangular prisms. If the sublimate is treated with ammonia, the solution allowed to evaporate, and silver nitrate added to the moist residue, a mixture of crystals is formed containing well-developed, oblique prisms of silver salicylate, up to 100μ long and 15μ wide.

Phenacetin.—The sublimate should be recrystallised from water, from which the phenacetin separates in two forms. The first of these consists mainly of flat prisms with oblique ends, at which twin-formation is frequently evident; they are 15 — 20μ wide and 100 — 150μ long. The subsidiary form comprises very long, flat, rectangular prisms, which invariably exhibit strong, oblique grooves. Platelets, as with acetanilide, are not formed. Characteristic nitrophenacetin crystals are prepared by mixing the sublimate with water and nitric acid and warming (without cover glass) until a yellow rim is formed. Groups of yellow needles soon separate, and slender needles, prisms, or long, flat, rectangular crystals with direct extinction are also produced. When similarly treated, salicylic acid, acetanilide, or antipyrine

yield only a colourless rim and white crystals. The phenacetin sublimate does not give the carbylamine reaction.

Methyl alcohol: Pyrogenic decomposition of — at high temperatures. E. Peytral. *Comptes rend.*, 1917, 165, 703—705.

METHYL alcohol decomposes rapidly at high temperatures, forming hydrogen, formaldehyde, and carbon monoxide, which may be explained either by the simultaneous reactions:—(1) $\text{CH}_3\text{OH} = \text{H}\cdot\text{CHO} + \text{H}_2$, (2) $\text{CH}_3\text{OH} = \text{CO} + 2\text{H}_2$, or by the successive reactions (1) $\text{CH}_3\text{OH} = \text{H}\cdot\text{CHO} + \text{H}_2$, (3) $\text{H}\cdot\text{CHO} = \text{CO} + \text{H}_2$. In the first case the ratio of carbon monoxide to formaldehyde would be independent of the duration of the reactions. In the second case, the ratio would vary with the duration of the reactions, and for small intervals of time would be proportional to it. Let x be the molecular mass of formaldehyde produced in time Δt , and z be the fraction of x decomposed in time Δt according to equation (3). The average mass of free aldehyde during time Δt is $\frac{x}{2}$, and if c is the velocity constant of reaction (3),

$z = C \frac{x}{2} \Delta t$, or $\frac{z}{x} = \frac{c}{2} \Delta t$. Measurements were made of p_1 (ratio of carbon monoxide to formaldehyde), p_2 (value of $\frac{z}{x}$), and n (number of mrgm.

mols. of gas passing per second) when a constant rapid current of methyl alcohol vapour was passed through a platinum tube of 2 mm. bore and 11 cm. in length heated to about 1150° C. Other factors being equal, the mean duration of the reaction is inversely proportional to n , and if the reaction proceeds by the successive equations (1) and (3), np_2 should be constant. The values found in six experiments varied only between 0.58 and 0.69, whereas p_1 varied from 0.87 to 16.75. Equations (1) and (3) therefore correctly represent the reactions.—F. Sp.

Nitriles: Delicate reaction of the —. S. Dezani. *Atti R. Accad. Sci. Torino*, 1917, 52, 826—833. *J. Chem. Soc.*, 1917, 112, ii., 519.

WHEN a solution of a nitrile (aliphatic or aromatic) is treated with an equal volume of hydrogen peroxide (12 vols.) and 2—3 drops of a 5% solution of ferric chloride, hydrogen cyanide is produced on boiling. This can be detected by test papers made by treating filter-paper with picric acid (1%), drying, and then immersing the paper in a 10% solution of sodium carbonate. If much nitrile is present, the paper turns blue, but with smaller quantities a red or brownish-red coloration is observed. Very small quantities of nitrile can be detected in this way, the limit being about 2×10^{-6} gm. of HCN.

Hydrargyrum thymolo-aceticum: Constitution of —. E. Rupp. *Arch. Pharm.*, 1917, 255, 191—197. *J. Chem. Soc.*, 1917, 112, i., 670—671.

THE so-called thymol-mercuric acetate does not contain ionisable mercury, and it is now shown that the substance is really 2,6-diacetato-mercurithymol, $\text{HO}\cdot\text{C}_6\text{H}(\text{CH}_3)(\text{C}_2\text{H}_5)(\text{Hg}\cdot\text{C}_2\text{H}_3\text{O}_2)_2$, since its mixture with glacial acetic acid and potassium nitrate is converted by sulphuric acid in the cold into 2,6-dinitrothymol. It is converted by hot 10% sodium hydroxide into the sodium derivative of 2,6-dihydroxymercurithymol, $\text{C}_{10}\text{H}_{13}\text{O}_3\text{NaHg}_2\cdot 3\text{H}_2\text{O}$, colourless plates, an aqueous solution of which is converted into the anhydride,

by carbon dioxide, into 2,6-dichloromercurithymol, colourless crystals, by a saturated solution of sodium chloride, and into 2,6-dinitratomercurithymol, colourless crystals, by 5% nitric acid. 2,6-Diiodomercurithymol has also been prepared.

The mercury in organic substances can be estimated by heating 0.3 gm. of the substance with 5 c.c. of sulphuric acid and 1 gm. of potassium nitrate, boiling the solution for ten to thirty minutes until it is colourless, cooling, adding permanganate until a permanent pink coloration is obtained, and, after the addition of a drop of hydrogen peroxide, titrating with *N*-10-thiocyanate with iron alum as indicator.

Oils: Some Indian essential —. P. Singh. *Indian Forest Records*, 1917, 5, [8]. *Perf. and Essent. Oil. Rec.*, 1917, 8, 325—329.

EXPERIMENTAL distillations of leaves of *Eucalyptus globulus* from the plantations on the Nilgiris led to the following conclusions:—(1) The leaves should be shade-dried *in situ*; (2) iron stills are suitable for distillation, and a catch still will hold back impurities and very heavy sesquiterpenes, giving as good an oil as is obtained by redistillation; (3) special plantations should be started for purposes of leaf supply. The oils produced contained about 56% of eucalyptol and were very uniform in composition. Distillation of Nilgiri Geranium (*Pelargonium graveolens*, L'Herit) plant gave a normal oil of good quality, and it is recommended that its cultivation be encouraged as an auxiliary to eucalyptus production. Comparative distillations of *Gaultheria fragrantissima* from Assam and the Nilgiris showed that the former plant is superior for commercial purposes, giving a higher yield of oil of wintergreen. Shillong is recommended as the best site for a distillery, but it is pointed out that to ensure a regular supply of the material it is necessary to foster the growth of the shrubs in the forests or to allow private enterprise to cultivate the plant.—L. PATENTS.

Metal albumin combinations: Manufacture of —. O. Imray, London. From Soc. of Chemical Industry in Basle. Eng. Pat. 410,935, Nov. 7, 1916. (Appl. No. 15,931 of 1916.)

ALBUMIN is extracted from a physiologically or pathologically modified part of the human or animal system, purified, and treated with a solution of a metallic salt such as ferric chloride, copper sulphate, gold chloride, etc. The resulting insoluble compound is washed and sterilised. It contains the metal in non-ionised condition, and the usual chemical reactions are given only after hydrolysis with a suitable enzyme. The compounds are used in testing for the corresponding condition or disease by reaction with the extracted serum from the suspected part, and then testing for the metal. For example, pregnancy may be tested for by reaction between an iron or copper placenta-albumin compound and the serum extracted from the blood of the patient. Cancer, syphilis, tuberculosis, etc., may be tested for in similar manner, using the metal preparation from a cancerous, syphilitic, tuberculous, or otherwise affected organ.—B. V. S.

Formaldehyde; Manufacture of—E. J. Boake, and A. Boake, Roberts and Co., Ltd., London, Eng. Pat. 110,787, Oct. 28, 1916. (Appl. No. 15,418 of 1916.)

THE reaction vessel in which a mixture of methyl alcohol and air is subjected to the action of catalytic agents for the production of formaldehyde, is heated by a suitable electric heater instead of by gas or fire.—J. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Two-colour screens for use in the production of photographs in colours; Making of—E. H. Tarlton, London, Eng. Pat. 110,993, Jan. 6, 1917. (Appl. No. 295 of 1917.)

A TWO-COLOUR screen in red and blue-green is obtained by forming one colour by dusting or printing or other suitable means on a transparent base, coating with a suitable emulsion, exposing through the screen, developing, and staining the resulting image to the other colour.—B. V. S.

Colouring of films for colour cinematography. H. Shorrocks, Manchester, Eng. Pat. 111,051, (Appl. Nos. 8127, June 7, and 10,386, July 19, 1917.)

THE positive film, containing alternating sets of pictures to be coloured red and green respectively, is passed through a bleaching bath, the series to be coloured green being first protected by covering with adhesive tape or by other suitable method. After washing and removal of the protection the film is passed through a composite staining bath containing Rhodamine, which stains the bleached pictures red, and an acid ferri-cyanide-citrate mixture, which stains the unbleached images blue-green. This method of staining red and green in one operation is applicable to other arrangements of the two sets of pictures.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Reduction of nitro- and nitroso compounds. Cusumano. See III.

PATENTS.

Explosive compound; Process for producing an—R. H. Twining and R. W. G. Wyckoff, Geneva, N.Y. U.S. Pat. 1,242,900, Oct. 9, 1917. Date of appl., Apr. 10, 1916.

A SALT of an alkali-metal with a "common inorganic acid" is heated with a non-volatile aromatic substance containing a negative group; e.g., sodium benzenesulphonate and sodium nitrate are heated together at the fusing temperature of sodium nitrate.—T. St.

Explosives; Manufacture of—R. G. Smith, Derry Village, N.H., Assignor to Raymond, Pynchon, and Co., New York, U.S. Pats. (A) 1,243,231 and (B) 1,243,351, Oct. 16, 1917. Date of appl., Feb. 3, 1916.

EXPLOSIVE compositions are produced by mixing the following ingredients in approximately the proportions given by weight:—(A) ammonium perchlorate 82, finely divided zinc 10, petroleum jelly 5, asphaltum varnish 3; (B) potassium perchlorate 53, ammonium perchlorate 18, sulphur 5, finely divided zinc 8, petroleum jelly 5, asphaltum varnish 3, alcohol 6, benzol 2.—T. St.

XXIII.—ANALYSIS.

Copper; Determination of— as sulphide and by electrolysis. F. L. Hahn. Z. anorg. Chem., 1917, 99, 201–248. J. Chem. Soc., 1917, 112, ii., 543.

IT is not possible to obtain pure cuprous sulphide by heating cupric sulphide in hydrogen, as the temperature at which the second atom of sulphur is completely driven off in a reasonable time is very close to that at which reduction to metallic copper takes place. Heating in carbon dioxide in a Rose crucible gives variable results. Many experiments with different kinds of tubes are described, the precipitates being heated in various atmospheres and at known temperatures. If air enters the tube or crucible, oxygen is always absorbed in time, even at moderate temperatures, sulphate being formed with increase of weight. At high temperatures oxygen causes a loss of weight, owing to the formation of cuprous oxide or metallic copper. Two methods have been found to give satisfactory results. One consists in heating the sulphide in a mixture of hydrogen sulphide and hydrogen, the proportions of which may vary within wide limits. A glazed Rose crucible is used, heating strongly over a Meker burner or blowpipe. During the first part of the heating the gas used is chiefly hydrogen sulphide, and towards the end chiefly hydrogen, separate bubbling tubes being used for the two gases. Two minutes suffices for 0.2 gm. of sulphide, ten minutes for larger quantities. The weight becomes quite constant, and the precipitate, being highly crystalline, is not hygroscopic. Ignition at first in hydrogen sulphide and then in carbon dioxide saturated with methyl alcohol also gives good results.

Copper may be estimated electrolytically in nitric acid solution. When pure platinum electrodes are used, platinum is dissolved at the anode, but platinum-iridium anodes are not attacked. Stationary gauze cathodes or rotating apparatus may be used, and the trace of copper remaining in solution is estimated colorimetrically.

†Sir Frederick A. Abel, Bart., F.R.S.	1882—1883.	†Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
†Walter Weldon, F.R.S.	1883—1884.	†Ivan Levinstein	1901—1903.
†Sir Wm. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.	†Sir Wm. Ramsay, K.C.B., D.Sc., F.R.S.	1903—1904.
E. K. Muspratt, LL.D.	1885—1886.	Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.
†David Howard	1886—1887.	†Edward Divers, M.D., D.Sc., F.R.S.	1905—1906.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.	†Enstace Carey	1906—1907.
†Ludwig Mond, Ph.D., F.R.S.	1888—1889.	Sir Boverton Redwood, Bart., D.Sc.	1907—1908.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.	†Raphael Meldola, F.R.S.	1908—1909.
†E. Rider Cook	1890—1891.	Prof. Ira Remsen	1909—1910.
J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.	Walter F. Reid	1910—1911.
†Sir John Evans, K.C.B., F.R.S.	1892—1893.	Rudolph Messel, Ph.D., F.R.S.	1911—1912.
†E. C. C. Stanford	1893—1894.	Pr. i. Marston T. Bogert, LL.D.	1912—1913.
Sir Edward Thorpe, C.B., LL.D., F.R.S.	1894—1895.	Sir William Crookes, O.M., F.R.S.	1913.
Thomas Tyrer	1895—1896.	Rudolph Messel, Ph.D., F.R.S.	1914.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.	Prof. G. G. Henderson, LL.D., D.Sc., F.R.S.	1914—1915.
Frank Clowes, D.Sc.	1897—1898.	Charles C. Carpenter, D.Sc.	1915—
Sir George T. Bellby, LL.D., F.R.S.	1898—1899.		

† Deceased.

LIST OF COUNCIL, 1916—1917.

President.

Dr. Charles C. Carpenter, South Metropolitan Gas Co., 709, Old Kent Road, London, S.E.

Vice-Presidents.

Prof. E. C. C. Baly, F.R.S., 14, Sunnyside, Prince's Park, Liverpool.
R. H. Clayton, 1, Parkfield Road, Didsbury, Manchester.
Sir Wm. Crookes, O.M., F.R.S., 7, Kensington Park Gardens, London, W.

Prof. F. G. Donnan, F.R.S., University College, Gower Street, London, W.C.

Henry Hemingway, 9 Albemarle Mansions, Hampstead, N.W.
Prof. G. G. Henderson, F.R.S., Royal Technical College, Glasgow.

D. Lloyd Howard, Uphall Works, Ilford, Essex.
Julius Huebner, Linden, Cheddle Hulme, Cheshire.

Prof. H. Lewis, 4, Osborne Terrace, Newcastle-on-Tyne.
Sir F. L. Nathan, 37, Cornwall Gardens, London, S.W.

Dr. Wm. H. Nichols, 25, Broad Street, New York City, U.S.A.
Harry Silvester, 78, Holyhead Road, Handsworth, Birmingham.

Ordinary Members of Council.

Dr. E. F. Armstrong, c/o J. Crosfield & Sons, Ltd., Warrington.
Prof. H. E. Armstrong, F.R.S., 55, Granville Park, Lewisham, S.E.

J. H. Coste, Utopia, Gloucester Road, Teddington.
E. V. Evans, 59, Harefield Road, Brockley, London, S.E.

Prof. W. R. E. Hodgkinson, 89, Shooter's Hill Road, Blackheath, S.E.

E. Grant Hooper, 16, Royal Avenue, Sloane Square, London, S.W.
R. D. Pullar, Brahan, Perth.

Dr. A. Ree, 15, Manbith Road, Withington, Manchester.
Walter F. Reid, Fieldside, Addlestone, Surrey.

Prof. R. F. Ruttan, McGill University, Montreal, Canada.
A. Gordon Salamon, 1, Fenchurch Avenue, London, E.C.

J. T. Wood, 62, Park Road, Nottingham.

Chairman and Secretaries of Sections (Ex-officio Members of Council).

Birmingham:

Chairman .. W. J. Rees, 75, Wentworth Road, Harborne, Birmingham.

Secretary .. F. R. O'Shaughnessy, 42, Temple Street, Birmingham.

Canadian:

Chairman .. T. H. Wardleworth, 32, St. Gabriel Street, Montreal, Canada.

Secretary .. Alfred Burton, 2, Liberty Street, Toronto, Canada.

Edinburgh:

Chairman .. Prof. Jas. Walker, F.R.S., 5, Wester Coates Road, Edinburgh.

Secretary .. Dr. Alex. Lauder, 13, George Square, Edinburgh.

Glasgow:

Chairman .. J. Macleod, Clairmont, 54 Albert Drive, Pollokshields, Glasgow.

Secretary .. Dr. G. S. Cruikshanks, Royal Technical College, Glasgow.

Liverpool:

Chairman .. John Gray, 3, Victoria Drive, Rock Ferry, near Birkenhead.

Secretary .. Dr. Alfred Holt, The University, Liverpool.

London:

Chairman .. A. R. Ling, 74, Great Tower Street, London, E.C.

Secretary .. T. D. Morson, 14, Elm Street, Gray's Inn Road, London, W.C.

Manchester:

Chairman .. J. H. Roseason, Sun Buildings, 2, Bridge Street, Manchester.

Secretary .. L. E. Vlies, Belmont, Gowan Road, Alexandra Park, Manchester.

Newcastle:

Chairman .. H. Pelle, Millburn House, Newcastle-on-Tyne.

Secretary .. L. F. Hooper, Pilgrim House, Newcastle-on-Tyne.

New England:

Chairman .. R. W. Neff, 22, India Square, Boston, Mass., U.S.A.

Secretary .. Alan A. Chaffin, Avery Chemical Co., Lowell, Mass., U.S.A.

New York:

Chairman .. Jerome Alexander, 225, West 108th Street, New York City, U.S.A.

Secretary .. Dr. Allen Rogers, Pratt Institute, Brooklyn, N.Y., U.S.A.

Nottingham:

Chairman .. Dr. R. M. Caven, University College, Nottingham.

Secretary .. John M. Wilkie, 5, Balmoral Avenue, West Bridgford, Nottingham.

Sydney, N.S.W.:

Chairman .. H. G. Smith, Technological Museum, Harris Street, Ultimo, Sydney.

Secretary .. S. E. Sibley, c/o Mauri Bros. & Thomson, Castlereagh Street, Sydney.

Yorkshire:

Chairman .. Prof. J. W. Cobb, The University, Leeds.

Secretary .. Thos. Fairley, 17, East Parade, Leeds.

Honorary Treasurer.

Thomas Tyrer, Stirling Chemical Works, Stratford, London, E.

Honorary Foreign Secretary.

Dr. R. Messel, F.R.S., 147, Victoria Street, London, S.W.

General Secretary.

J. P. Longstaff, D.Sc., Broadway Chambers, Westminster, S.W.
(Telegraphic address:—"Induchem," Vic., London;
Telephone No., 715 Victoria.)

Editor.

T. F. Burton, "Manna Mead," Upper Warlingham, Surrey.

LIST OF MEMBERS.

THE MEMBERSHIP ON 23RD APRIL, 1917 = 4262

(ADDRESSES CORRECTED TO 16TH NOVEMBER 1917)

NOTE: "O.M." INDICATES AN ORIGINAL MEMBER.

A

1912. Abady, Jacques, 1, Westminster Palace Gardens, London, S.W., and (Journals) 11, Lyndhurst Road, Hampstead, N.W., Barrister-at-Law, M.Inst.Mech.E.
1912. Abegg, Dr. Fritz, 28, Gordon Street, Perth Amboy, N.J., U.S.A., Chemist.
1903. Abraham, Herbert, 316, West 79th Street, New York City, U.S.A., Chemist.
1909. Acheson, Dr. Edward G., 35, West 42nd Street, New York City, U.S.A., President, Acheson Oildag Co.
1902. Acker, Chas. E., 80, Main Street, Ossining, N.Y., U.S.A., Manufacturer.
1911. Acton, Leonard T., c/o Wm. Davies Co., Ltd., 521, Front Street East, Toronto, Canada, Chemist.
1913. Acton, Walter, Mossvale Cottage, Greenock Road, Paisley, Scotland, Works Manager and Chemist.
1916. Adam, A. T., 14, Links Place, Musselburgh, Scotland, Metallurgical Chemist.
1912. Adam, G. H., "Lintrose," Malakoff Street, Marrickville, Sydney, N.S.W., Customs Analyst.
1914. Adam, N. K., 21, Barton Road, Cambridge, Chemist (Naval Air Service).
1916. Adam, W. G., Tar and Ammonia Products Works, Beckton, E., Chemical Engineer.
1892. Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham, Science Lecturer.
1916. Adams, Chas. A., 9, Christchurch Place, Hampstead, N.W., Analytical Chemist.
1911. Adams, E. Bryan, c/o Curtis's and Harvey, Ltd., Explosives Works, Cliffe at Hoo, Kent, Chemist.
1897. Adama, Thos. H., 7, Douglas Street, Derby, Analyst.
1895. Adamson, G. P., The Baker and Adamson Chemical Co., Easton, Pa., U.S.A., Manufacturing Chemist.
1917. Adamson, John, Greenways, Dundonald Drive, Leigh-on-Sea, Essex, Works Chemist.
1891. Adcock, S. R., St. Helen's Smelting Co., Ltd., Atlas Court, St. Helen's, Lancashire, Analytical Chemist.
1901. Addison, Leonard, c/o Messrs. Burt, Boulton & Haywood, Prince Regent's Wharf, Silvertown, Victoria Docks, E., Chemist.
1898. Adgate, M., Naugatuck, Conn., U.S.A., Chemist.
1913. Adkins, Linden R., 12, Fenwick Street, Rochester, N.Y., U.S.A., Oil Refinery Chemist.
1917. Adlam, Edwin G., c/o George Adlam & Sons, Ltd., Bristol, Engineer.
1896. Adler, Dr. Leon N., Adler Colour and Chemical Works, 100, William Street, New York City, U.S.A., Manufacturing Chemist.
1888. Adriance, Dr. John S., Williams College, Williamstown, Mass., U.S.A., Analytical Chemist.
1899. Adrot, Léon, 16, Palmer Avenue, Port Richmond, N.Y., U.S.A., Chemist.
1917. Ainsworth, W. T. T., 8, Radeliffe Road, West Bridgford, Nottingham, Analyst (Boots Pure Drug Co.).
1912. Aitken, James, c/o National Synthetic Co., Perth Amboy, N.J., U.S.A., Chemist.
1886. Aitken, J. B., Hall Nook, Penketh, by Warrington, Chemical Manufacturer.
1883. Albright, G. S., Bromesberrow Place, Ledbury, Chemical Manufacturer.
- O.M. Albright, W. A., 29, Frederick Road, Edgbaston, Birmingham, Chemical Manufacturer.
1906. Alcock, Frank H., 5, King Alfred's Place, Broad Street, Birmingham, Analyst.
1914. Alcock, W. J., c/o War Office, High Explosives Dept., Storey's Gate, Westminster, S.W., Alkali Works Manager.
1909. Alén, Dr. J. E., Stadachemistens Laboratorium, Göteborg, Sweden, Public Analyst.
1899. Alexander, D. Basil W., c/o The Barber Asphalt Paving Co., 1328, Tribune Building, Chicago, Ill., U.S.A., Chemist.
1916. Alexander, Geo., 3, Kingston Terrace, Leeds, Works Chemist.
1913. Alexander, Jas., 2208, Allendale Street, Walbrook, Baltimore, Md., U.S.A., Research Chemist.
1900. Alexander, Jerome, c/o National Gum and Mica Co., 59th Street and 11th Avenue, New York City, U.S.A., Chemist.
1917. Alexander, Thomas J. R., Viewfield, Eglington Road, Ardrossan, Scotland, Research Chemist.
1912. Alexander, Walter, National Gum and Mica Co., 59th Street and 11th Avenue, New York City, U.S.A., Secretary.
1883. Alexander, W. T., Crumnock, Eccles, Manchester, Drysalter.
1906. Allan, David, c/o Price's Patent Candle Co., Ltd., Bromborough Pool Works, near Birkenhead, Chemist.
1891. Allan, F. H. Tielke, 164, Pearson Street, Chicago, Ill., U.S.A., Technical Chemist.
1898. Allan, John, 77, Northern Grove, West Didabury, Manchester, Chemist.
1917. Allan, John S., Glenfield Starch Works, Paisley, Starch Manufacturer.
1909. Allan, Maurice, 103, Burford Road, Nottingham, Soapmaker.
1907. Allard, M. L., c/o Dunlop Tire and Rubber Goods Co., Ltd., Toronto, Canada, Chemist.
1902. Allbright, Wm. B., 4937, Madison Avenue, Chicago, Ill., U.S.A., Chemical Engineer.
1915. Allchin, L. J., 92, Monton Road, Eccles, Manchester, Managing Chemist.
- O.M. Aldred, C. H., 8, St. Margaret's Road, Plumstead Common, Woolwich, S.E., Technical Chemist.
1898. Alleman, Dr. Gellert, Swarthmore College, Swarthmore, Pa., U.S.A., Professor of Chemistry.
1903. Allen, Chas. A., Overdale, Sunnyhurst, Darwen, Lancashire, Chemist.
1911. Allen, Harry L., 900, Jersey Avenue, Elizabeth, N.J., U.S.A., Chemist.
- O.M. Allen, John, 164, Upper North Street, Poplar, E., Manufacturing Chemist.
1916. Allen, William R., c/o Watson, Jack & Co., Ltd., 720, Power Building, Montreal, Canada, Manager Chemical Department.
- O.M. Allhusen, A., Beadnell Tower, Chathill, Northumberland, Chemical Manufacturer. Journals to Mr. Oliver, United Alkali Co., Ltd., Allhusen Works, Gateshead-on-Tyne.
1886. Allibon, G. H., J. Windsor Gardens, University Road, Belfast, Ireland, Chemical Works Manager.
1916. Alliot, E. A., c/o Manlove, Alliot & Co., Ltd., 23, King Street, Manchester, Chemical Engineer.
1917. Allott, Fred. W. J., 22, Pall Mall, Liverpool, Industrial Photographic Paper Maker.
1905. Allpass, Jas., 9, Albert Square, Manchester, Secretary.
1917. Allpass, Jas. T., Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.
1912. Almy, Charles, jun., c/o Virginia Products Corporation, Baltimore, Md., U.S.A., Chemical Engineer.

1899. Alsop, Wm. K., Ridgway, Pa., U.S.A., Chemist.
1917. Alston, Richard A., 4, Colley Street, Old Trafford, Manchester, Chemist.
1910. Amin, Bhailal D., The Alembic Chemical Works Co., Ltd., Gorwo Road Camp, Baroda, India, Chemical Agent.
1905. Amory, L. H., c/o Messrs. J. Heathcoat and Co., Tiverton, Devon, Lace Manufacturer.
1914. Anders, H. R., 144, Rector Street, Perth Amboy, N.J., U.S.A., Chemist.
1916. Andersen, Aage, c/o Planters Margarine Co., Ltd. and Brooklyn House, Chapel Street, Hyde, Cheshire, Works Manager.
1914. Anderson, Albert E., c/o Procter and Gamble Co., Ivorydale, Ohio, U.S.A., General Superintendent.
1915. Anderson, E., Natal Soap Works, Ltd., P.O. Box 1044, Durban, Natal, S. Africa, Soap Manufacturer.
1910. Anderson, Jas. R. V., School of Mines, Bendigo, Victoria, Australia, Lecturer in Chemistry and Metallurgy.
1900. Anderson, Jas. W., Cliffe Lodge, Cliffe, nr. Rochester, Kent, Analytical Chemist. Retain Journals.
1917. Anderson, John W., Addiewell Chemical Works, West Calder, Scotland, General Works Manager.
1914. Anderson, P. J., Marischal College, Aberdeen, Librarian.
1899. Anderson, Robt. T. R., 42, Roslea Drive, Dennistoun, Glasgow, Technical Chemist.
1894. Anderson, Dr. W. Carriek, 7, Scott Street, Garnet Hill, Glasgow, Consulting Chemist.
1905. Andreae, Dr. E. P., Crestalta, Woodlands Road, Beckley, Kent, Chemist.
1907. Andrews, Chas. T., c/o W. S. Andrews, The British Metals Extraction Co., Ltd., Llansamlet, R.S.O. Glam., Chemist.
1899. Andrews, Dr. Clement W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Librarian.
1912. Andrews, Ernest R., "Nutfield," Druce Road, Dulwich, S.E., Analytical and Consulting Chemist.
1914. Andrews, Joseph C., 123, Vine Street, New Britain, Conn., U.S.A., Chemical Engineer.
1916. Andrews, William, 45, Snowdon Road, Eccles, Lancashire, Works Manager.
1903. Andrews, Wm. H., 79, Tonawanda Street, Buffalo, N.Y., U.S.A., President (Varnish Works).
1913. Andrews, W. O., P.O. Box 2671, Johannesburg, South Africa, Analytical Chemist.
1903. Anfilogoff, N. A., Thames Haven, Essex, Chemist and Petroleum Refiner.
1913. Annan, J. G., Elm Cottage, Addiewell, Midlothian, Chief Chemist (Mineral Oil Works).
1892. Annandale, C. J. R., The Briary, Shotley Bridge, Co. Durham, Paper Maker.
1894. Ansbacher, L. A., 527, Fifth Avenue, New York City, U.S.A., Colour Manufacturer.
1902. Anthony, John, 217, King Street East, Toronto, Canada.
1916. App, John C., Box 977, Charleston, Kanawha, West Va., U.S.A., City Chemist and Bacteriologist.
1895. Appleby, Prof. W. R., Minnesota School of Mines, University of Minnesota, Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
1900. Appleyard, Geo. H., 1, Carlton Terrace, Hornsea, East Yorks, Analytical Chemist.
1905. Appleyard, Jas. R., Royal Technical Institute, Salford, Lecturer.
- O.M. Archbutt, Leonard, The Yews, Madeley Street, Derby, Analytical Chemist.
1899. Archdale, T. Henry, 38, Whitobirk, Blackburn, Manager of Tar and Ammonia Works.
1904. Archdale, Wm., Sandhutton, Hill Lane, Blackley, Manchester, Manager of Chemical Works.
1901. Ardagh, Prof. Edw. G. R., Faculty of Applied Science, University of Toronto, Canada, Chemist.
1900. Arden, Edw., Holmleigh, Marlborough Road, Flixton, Manchester, Chemist.
1902. Armstrong, Edward E., Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Manufacturing Chemist.
1905. Armstrong, Dr. E. Frankland, c/o J. Crosfield and Sons, Ltd., Warrington, Technical Chemist.
1899. Armstrong, Richard, Saul Street Soap Works, Preston, Lancashire, Soap Manufacturer.
1905. Arnold, Frank L., 32, School Street, North Woburn, Mass., U.S.A., Chemist.
1899. Arnott, G. W. Campbell, c/o Fertiliser Manufacturers' Association, 68-70, Fenchurch Street, London, E.C., Agricultural Chemist.
1912. Arny, R. V., 115, West 68th Street, New York City, U.S.A., Teacher and Chemist.
1915. Arundel, Edgar, 99, Poppleton Road, Leytonstone N.E., Chemist.
1911. Asahina, Koji, Osaka Technical College, Tamae-cho, Osaka, Japan, Chemist.
1901. Asano, K., Ashio Copper Mine, Shimozuke, Japan, Consulting Mining Chemist.
1908. Ashbury, J. W., c/o John Brown and Co., Ltd., Laboratory, Atlas Works, Sheffield, Chief Chemist.
1914. Ashcroft, Edgar A., 65, London Wall, E.C., Technical Chemist.
1903. Ashley, Frank R., c/o Western Chemical Manufacturing Co., Denver, Colo., U.S.A., Manufacturing Chemist.
1917. Ashmore, Stanley A., 57, St. Aidan's Road, East Dulwich, London, S.E., Research Chemist.
1915. Ashton, Jack, 110, Hubert Street, Leichhardt, New South Wales, Australia, Oil Chemist.
1890. Ashton-Bost, W. D., See Bost, W. D. Ashton.
1894. Ashworth, Arthur, Fernhill Chemical Works, Bury, Lancs., Chemical Manufacturer.
1908. Ashworth, D. Irving, P.O. Box 503, Wappingers Falls, N.Y., U.S.A., Chemist.
1907. Aspey, Urban, jun., New Station Soap Works, School Close, and (Journals) Tonbridge Villa, Tonbridge Place, Leeds, Works Manager and Chemist.
1898. Aspinall, Thos., 34, Chorley New Road, Bolton, Analytical and Manufacturing Chemist.
1900. Aston, Bernard C., Box 40, P.O., Wellington, New Zealand, Chemist.
1915. Atack, F. W., 88, Claude Road, Chorltonville, Manchester, Demonstrator in Chemistry.
1891. Atkins, C. E., The Heath, Redbourn, Herts., Chronometer Maker.
1885. Atkinson, A. J., 10, North Church Street, Cardiff, Analytical Chemist.
1912. Atkinson, F. C., c/o American Hoving Co., Gent Avenue, Indianapolis, Ind., U.S.A., Chemist.
1911. Atkinson, James E., The Sheffield Testing Works Ltd., Blonk Street, Sheffield, Analytical Chemist.
1915. Atlas, Henry, c/o Yalding Manufacturing Co., Ltd. Yalding, Kent, Technical Chemist.
1905. Atteaux, F. E., 176, Purchase Street, Boston, Mass., U.S.A., Dyestuff Importer and Manufacturer.
1900. Atwood, Frank W., 216, Milk Street, Boston, Mass., U.S.A., Chemist.
1895. Auchterlonie, Wm., c/o Clark Thread Co., Newark, N.J., U.S.A., Dyeworks Manager.
1897. Auger, Chas. L., Room 24, First National Bank Building, Paterson, N.J., U.S.A., Silk Dyer.
1911. Austin, Fred. J., 343, Sixth Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1913. Austin, Wm. L., 65, Lewisham Hill, Lewisham, S.E., Analytical Chemist.
1901. Auty, Albert M., c/o John Smith and Sons, Ltd., Field Head Mills, Bradford, Works Chemist.
1902. Avery, D., 387, Barker's Road, Kew, Melbourne, Vic., Australia, Teacher of Chemistry.
1910. Ayers, Gilbert F., Dynamite Factory, Modderfontein, Transvaal, Chemist.

B

1908. Babington, Fred. W., Laboratory, Customs Dept., Ottawa, Canada, Analyst.
1913. Backus, Cecil F., c/o Atlas Powder Co., Wilmington, Del., U.S.A., Chemist.
1913. Bacon, Raymond F., Mellon Institute of Industrial Research, The University, Pittsburgh, Pa., U.S.A., Associate Director.
1911. Baddiley, James, c/o Levinstein, Ltd., Crumpsall Vale Chemical Works, Blackley, Manchester, Research Chemist.
1917. Bader, Dr. Walter, Avondale, Prestwich Park, Manchester, Works Chemist (Levinstein, Ltd.).
1897. Badoek, Stanley H., Holmwood, Westbury on Trym, near Bristol, Smelter.
1898. Backeland, Dr. Leo H., Snug Rock, Harmony Park, Yonkers, N.Y., U.S.A., Research Chemist.
1912. Bagley, Fred. P., c/o George H. Morrill Co., Norwood, Mass., U.S.A., Ink Manufacturer.
1917. Bailes, Henry, 13, Clarendon Road, Smethwick, Staffs., Technical Chemist.
1913. Bailey, Alan M., c/o The National Explosives Co., Ltd., Hayle, Cornwall, Analytical Chemist.
1903. Bailey, Prof. E. H. S., The Library, University of Kansas, Lawrence, Kas., U.S.A., Professor of Chemistry.
1885. Bailey, Edwin M., Almond Hill, Pumphreston, Mid Calder, Scotland, Technical Chemist.
1908. Bailey, Frank W., 25, Lord Street, Glossop, Derbyshire.
1883. Bailey, Dr. G. H., Kinlochleven, Argyll, Scotland, Chemist.
1903. Bailey, Harold J., 10, Park Road, Pendleton, Manchester, Alkali Inspector.
1906. Bailey, Ralph W., 66, Cherry Street, Elizabeth, N.J., U.S.A., Chemist.
1888. Bailey, Dr. T. Lewis, 21, Shavington Avenue, Chester, H.M. Inspector of Alkali Works.
1910. Baillie, Dr. Thomas B., 5, Mossiel Avenue, Ainsdale, Lancashire, Analytical Chemist (Love Lane Sugar Refinery).
1916. Baillie, W. L., 14, Greenholme Road, Eltham, Kent, Research Chemist.
1902. Bain, Prof. Jas. Watson, Faculty of Applied Science, The University, Toronto, Ont., Canada, Chemist.
1915. Bainbridge, J. R., Inglebrook, Arklow, Co. Wicklow, Ireland, Chemist.
1911. Baird, Douglas H., 14, Cross Street, Hatton Garden, London, E.C., Scientific Instrument Maker.
1908. Baird, M. M., Westfield, Rutherglen, Glasgow, Analytical Chemist.
1891. Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.
1895. Baird, W. Raymond, 271, Broadway, New York City, U.S.A., Patent Lawyer.
1890. Bairstow, John, Burley, Queen's Park, Chester, Chemical Works Manager.
1903. Baker, Arthur, "Denhurst," Earnsdale, Darwen, Lancs., Paper Mill Chemist.
1916. Baker, Arthur J., Yate Chemical Works, Yate, near Bristol, Works Chemist.
1916. Baker, Bertram, 44, Melton Road, West Bridgford, Nottingham, Analytical Chemist.
1913. Baker, Bertram F., Mayfield, New Chester Road, Bromborough, Cheshire, Technical Chemist.
1902. Baker, Chas. F., Technical College, Sunderland, Lecturer in Chemistry.
1910. Baker, C. Kerslake, 16, Change Alley, Sheffield, Analytical Chemist.
1901. Baker, F. Guy Stirling, The Brewery, Chiswell Street, London, E.C., Brewer's Chemist.
1883. Baker, Harry, Epworth House, Moughland Lane, Runcorn, Analytical Chemist.
1904. Baker, John T., c/o J. T. Baker Chemical Co., Phillipsburg, N.J., U.S.A., Manufacturing Chemist.
1892. Baker, Julian L., Ardingley, Linden Avenue, Maidenhead, Brewing and Sugar Chemist.
1886. Baker, Theodore, 488, Du Pont Building, Wilmington, Del., U.S.A., Analytical Chemist.
1910. Baker, Dr. Thos., 4, The Crescent, Doncaster Road, Rotherham, Chemist and Metallurgist.
1912. Balch, Prof. Alfred W., 41, Linden Street, Brookline, Mass., U.S.A., Professor of Biological Chemistry.
1914. Baleon, 2nd Lt. P. C. (R.E.), "Bodryn," Cadnant Park, Conway, N. Wales, Chemist.
1912. Baldraceo, Cav. Prof. Dr. Giacinto, R. Conceria Scuola Italiana, Corso Cirié, ang. Via Biella, Turin, Italy, Leather Trades Chemist.
1903. Baldwin, F. H., Bergenport Chemical Works, Bayonne, N.J., U.S.A., Superintendent.
1903. Baldwin, Dr. H. B., 927, Broad Street, Newark, N.J., U.S.A., Chemist (Dept. of Public Health).
1903. Ball, S. F., 289, East 201st Street, New York City, U.S.A., Analytical Chemist.
1889. Ballantyne, Horatio, 75, Chancery Lane, London, W.C., Analytical and Consulting Chemist.
1903. Ballantyne, W. H., 111, Hatton Garden, London, E.C., Patent Agent's Assistant.
- O.M. Ballard, Edw. G., 8, Lansdowne House, Lansdowne Road, Holland Park, London, W., Alkali Works Inspector (retired).
1915. Balmforth, Charles, 29, Avondale Road, Morecambe, Lancs., Analytical Chemist.
1910. Baly, Prof. E. C. C., F.R.S., 14, Sunnyside, Prince's Park, Liverpool, Professor of Inorganic Chemistry.
- O.M. Bamber, H. Keway, Outram House, Addiscombe, Surrey, Consulting Chemist.
1894. Bamber, H. K. G., Ingress House, Greenhithe, Kent, Cement Works Manager.
1917. Bamfield, Albert E., c/o Brazil Straker & Co., Ltd., Lodge Causeway, Fishponds, Bristol, Engineer.
1898. Bamford, Harry, 70, Duckworth Terrace, Bradford, Yorks, Dyer.
1906. Baneroff, John, Wilmington, Del., U.S.A., Bleacher and Dyer.
1916. Banker, S. G., Belle Vue, 36, Chowpaty, Bombay, India, Leather Chemist.
1913. Banks, A. J., c/o The Ogilvie Flour Mills Co., Ltd., Montreal, Canada, Analyst.
1916. Banner, George E., c/o S. Banner & Co., Ltd., 8, Fazakerley Street, Liverpool, Managing Director.
- O.M. Bannister, W., "Dunloc," Bramley Hill, South Croydon, Manufacturing Chemist.
1910. Barbary, Capt. J. Ewart (R.A.), Mt. Whistle, Camborne; Journals, Ministry of Munitions, C.M.4 (T.), Grand Hotel, London, Explosives Chemist.
1909. Barber, C. Douglas, 20, Champion Road, Upminster Essex, Chemist.
1914. Barber, Charles F. L., 12, Queen's Terrace, Station Road, Otley, Yorks., Leather Chemist.
1915. Barber, Christopher, British General Tar Products, Ltd., Hayes Road, Cadishead, near Manchester, Chemical Engineer.
1908. Barber, Percy S., The Reform Food Stores, 3, Richmond Street, Liverpool, Chemist.
1917. Barber, Thos. W., 10, Esplanade, Seaford, Sussex, Consulting Engineer.
1912. Barclay, William R., 31, Glenalmond Road, Ecclellah, Sheffield, Manager of Electroplating Factory and Lecturer in Electro-Metallurgy.
1892. Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.
1907. Bardorf, C. F., c/o St. Lawrence Sugar Refineries, Ltd., Montreal, Canada, Chief Chemist.
1915. Bardsley, J. R., "Bunawang," Lea Avenue, Five Dock, Sydney, N.S.W., Australia, Hat Manufacturer.
1902. Barker, Hugh S., 32, Cumberland Avenue, Sefton Park, Liverpool, Laboratory Furnisher.
1916. Barker, John E., 295, Mansfield Road, Little Chester, Derby, Glass Works Manager.
1912. Barker, Dr. Jonathan T., Victoria Villa, Halkyn Street, Flint, North Wales, Chemist.
1916. Barker, W. R., 61, Grove Street, Barnsley, Yorks, Glass Works Manager.
1895. Barlow, Clinton W., 104-112, East 25th Street, New York City, U.S.A., Merchant.

1901. Barlow, John J., Broadway, Accrington, Calico Printer's Chemist.
1916. Barlow, Walter, II., 29, Warwick Gardens, Ilford, Chemist.
1899. Barlow, Wm., 23, Alton Terrace, Fairfield, Manchester, Analytical Chemist.
1908. Barnes, Alfred, Box 556, Pretoria, Transvaal, Dealer in Minerals.
1906. Barnes, A. G., c/o Hasland Coking Co., Grassmoor Collieries, Chesterfield, Colliery Proprietor.
1914. Barnes, Edward A., c/o American Barium Co., South San Francisco, San Mateo Co., Cal., U.S.A., Chemical Engineer.
1905. Barnes, F. V., Gas Works, Todmorden, Engineer and Manager.
1884. Barnes, H. J., Phoenix Chemical Works, Haekney Wick, N.E., Manufacturing Chemist.
1916. Barnes, John F., Oil Mills, Stanningley, Leeds, Oil Manufacturer.
1884. Barnes, Jonathan, 301, Great Clowes Street, Manchester, Analytical Chemist.
- O.M. Barnes, Jos., Highbrake, Arnside, Westmorland, Analytical Chemist.
1916. Barnes, Wm. H., c/o Follows and Bate, Ltd., Engineers, Gorton, Manchester, Manager and Representative.
1912. Barnett, E. de Barry, 9, Collingham Road, South Kensington, S.W., Chemist.
1917. Barnett, Walter Leigh, 18, Carden Road, Peckham Rye, London, S.E., Chemist.
1904. Baron, Wm. Briscoe, "Ingleside," Woodfield Road, Cheadle Hulme, Stockport, Chemist.
- O.M. Barr, J., Dinting Vale, Dinting, near Manchester, Chemical Manager.
1916. Barr, James C., 180, West Regent Street, Glasgow, Chemical Merchant.
1915. Barraclough, C. E., c/o J. Crossley & Sons, Ltd., Dean Clough Mill, Halifax, Yorks., Chemist.
1914. Barraclough, Dennis H., North Brierley Sewage Works, Oakenshaw, Bradford, Chemist.
1890. Barraclough, Wm. H., Westholme, Chapeltown, near Sheffield, Analytical Chemist.
1890. Barrett, Arthur A., 139, Viale San Martino, Messina, Sicily, Manufacturer of Essential Oils.
1907. Barrett, Maurice, 138, Woodsley Road, Leeds, Technical Chemist (Leeds Fireclay Co.).
1912. Barrow, Jas. V., c/o Messrs. H. Holmes and Sons, Portland Road, Newcastle-on-Tyne, Works Chemist.
1900. Barrow, Jos., c/o Messrs. Edward Cook & Co., Ltd., The Soapery, Bow, E., Chemist.
1915. Barrowcliff, M., 13, Shirley Road, Nottingham, Research Chemist.
1906. Barrs, Chas. E., "Buena Vista," 58, South Hill Park, Hampstead, N.W., Analyst.
1905. Barry, Eugene, Ayer, Mass., U.S.A., Leather Manufacturer.
1916. Barlett, Edward E., c/o Mellon Institute, Pittsburg, Pa., U.S.A., Treasurer.
1915. Barton, B. Cyril, c/o Messrs. Barton & Waterhouse, Sun Chambers, Lowgate, Hull, Seed Crusher.
1893. Barton, G. E., 227, Pine Street, Millville, N.J., U.S.A., Technical Chemist.
1903. Barrio, Geo. F., 42, Brock Street, Luton, Beds., Managing Chemist.
1905. Baruch, Edgar, 704, Wright & Callender Building, Los Angeles, Cal., U.S.A., Chemical Engineer.
1910. Barwick, F. W., Chamber of Commerce Testing House, Royal Exchange, Manchester.
1915. Bashore, E. G., La Tourette Hotel, Bayonne, N.J., U.S.A., Chemist.
1895. Baskerville, Dr. Chas., College of the City of New York, New York City, U.S.A., Professor of Chemistry.
1884. Bassett, H., 26, Belitha Villas, Barnsbury, N.
1908. Bassett, Professor Henry, jun., The Myrtles, Southwood Road, New Eltham, S.E., Professor of Chemistry.
1899. Bassett, Wm. H., Main Street, Cheshire, Conn., U.S.A., Chemist.
1890. Bate, William, Upton Villa, Hayle, Cornwall, Technical Chemist (National Explosives Co., Ltd.).
1903. Bateman, A. H., Eridge, Shooter's Hill, Woolwich, S.E., Chemist.
1913. Bateman, James T., 34, Bridge Avenue, Hammer-smith, W., Engineer and Works Manager.
1912. Bates, D. M., Lewiston Bleachery and Dye Works, Lewiston, Maine, U.S.A., General Manager.
1914. Bates, John S., 700, University Street, Montreal, Canada, Superintendent. (Forest Products Laboratory.)
1914. Battersby, W. H., Corporation Gas Works, Elton, Bury, Lanca., Chief Chemist.
1885. Batty, R. B., Wharnciffe, Erdington, near Birmingham, Nickel Works Manager.
1910. Battye, Horace G., 28, Roman Place, Street Lane, Roundhay, Leeds, Chemist and Works Manager.
1903. Baty, E. J., c/o Thermo-electric Ore Reduction Corporation, York Street, Luton, Beds., Chemist.
1903. Bauer, Geo. W., 660, Sacramento Street, San Francisco, Cal., U.S.A., Vice-President and Chemist (Hop and Malt Co.).
1915. Baumann, Dr. L., Manufacture Emile Zündel, Moscow, Russia, Managing Director of Printworks.
1910. Baxter, F. Stanley, 5, York House, College Place, St. Pancras, London, N.W., Chemist.
1913. Baxter, Harold R., c/o Aktiebolaget J. and G. Cox, Kungsgatan 13, Gothenburg, Sweden, Manager (Glue Works).
1898. Baxter, John G., Glenarm, Lennox Avenue, Gravesend, Kent, Chemist.
1915. Bayley, Frank, The Bungalow, Pound Road, Warley, Langley Green, Birmingham, Technical Chemist.
1908. Bayly, Percival G. W., Mines Dept. Laby., Spring Street, Melbourne, Victoria, Australia, Government Metallurgical Chemist.
1886. Beadle, Clayton, Oakbank, Lansdown Road, Sidcup, Kent, Consulting Chemist.
1917. Bean, Philip L., No. 3 Staff Quarters, Eastriggs, Dornock, Dumfriesshire, Works Chemist.
1911. Beard, Stanley D., Lederle Antitoxin Laboratories, Pearl River, N.Y., U.S.A., Biological Chemist.
1907. Beardsley, Dr. Alling P., 119, East Maple Avenue, Bound Brook, N.J., U.S.A., Chemist (New Haven Gas Co.).
1909. Bearpark, Arthur F., P.O. Box 497, Durban, South Africa, Consulting Chemist and Chemical Engineer.
1908. Beasley, Fred. G., Chartley Croft, Gateacre, near Liverpool, Metallurgical Chemist.
1905. Beasley, Jno. K., c/o The Borneo Co., Kuching, Sarawak, Metallurgical Chemist.
1897. Beaver, Chas. J., Rangemoor, Crescent Road, Hale, Cheshire, Chemist.
1905. Beckers, Dr. Wm., East 83rd Street and Ditmar Avenue, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1909. Becket, Fredk. M., 403, Jefferson Avenue, Niagara Falls, N.Y., U.S.A., Chief Metallurgist, Electro Metallurgical Co.
1912. Beckett, Dr. E. G., No. 1, Sandhilla, Ardeer, Stevenston, Ayrshire, Analytical Chemist.
1899. Bedford, Alf. C., c/o Standard Oil Co., 26, Broadway, New York City, U.S.A., Chemical Merchant.
1891. Bedford, Chas. S., Recella, Weetwood, Headingley, Leeds, Manufacturing Chemist.
1891. Bedford, James E., "Arnccliffe," Shire Oak Road, Headingley, Leeds, Chemical Manufacturer.
1911. Bedford, G. E., Aspley Dyeware Mills, Huddersfield, Works Chemist.
- O.M. Bedson, Prof. P. Phillips, Armstrong College, Newcastle-on-Tyne, Professor of Chemistry.
1901. Beevers, Clifford J., c/o The Shipley Grease and Fertiliser Co., Westfield Works, Wrose Hill, Shipley, Yorks, Analyst.
- O.M. Beilby, Sir George T., F.R.S., 11, University Gardens, Glasgow, Chemical Engineer.

1912. Belaiew, Col. Nicolai T., c/o Russian Government Supply Committee, India House, Kingsway, London, W.C., Lecturer in Metallurgy and Chemistry.
1884. Bell, Sir Hugh, Bart., Middlesbrough-on-Tees, Soda and Iron Manufacturer.
1900. Bell, Hugh P., Census and Statistics Office, Ottawa, Canada.
1886. Bell, J. Ferguson, Derby Gas Light and Coke Co., Derby, Gas Engineer.
1917. Bell, Jerome B., jun., c/o Canadian Explosives, Ltd., Transportation Building, Montreal, Canada, Chemical Manager.
1907. Bell, Marcus, Defence Dept., Melbourne, Victoria, Chemist.
1905. Bell, Miss M. M., Tulane University Library, New Orleans, La., U.S.A., Librarian.
1915. Bell, Wm., c/o Parry and Co., Ranipettai, North Arcot Dt., Madras Presidency, India, Works, Chemist.
- O.M. Bendix, D., 371, Romford Road, Forest Gate, E., Managing Chemist, British Alizarin Co., Ltd.
1903. Benham, Keith, Deans Hill, Stafford, Analytical and Consulting Chemist.
1917. Benjamin, Edward O., 177, Hillside Avenue, Newark, N.J., U.S.A., Chemist and Engineer.
- O.M. Benjamin, Dr. M., Smithsonian Institution, Washington, D.C., U.S.A., Consulting Chemist.
1899. Bennett, Alex. H., Via Giuseppe La Farina, Messina, Sicily, Analytical Chemist.
1907. Bennett, H. Garner, 115, Grovehill Road, Beverley, Yorks, Leather Chemist.
1915. Bennett, Walter, 37, Town Street, Bramley, Leeds, Analytical Chemist.
1909. Benson, George F., Edwardsburg Starch Co., Cardinal, Ontario, Canada, President and Managing Director.
1901. Bentley, Wm. H., 12, Cromwell Terrace, Irlam, near Manchester, Technical Chemist.
1890. Bentz, Ernest, 30, Manley Road, Whalley Range, Manchester, Technical Chemist.
1893. Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1907. Berk, Paul F., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1916. Berkeley, Cyril J., 2412, Alder Street, Vancouver, B.C., Canada, Agricultural Chemist.
1900. Birmingham, John, jun., c/o Union Powder Corporation, 50, Church Street, New York City, U.S.A., Superintendent.
1889. Bernard, Jas., jun., c/o The United Alkali Co., Ltd., Netham Works, Bristol, Chemical Works Manager.
1897. Berry, Albert E., Abbotsleigh, Wanstead, Essex, Works Manager.
1911. Berry, Arthur G. V., c/o Sir Boyerton Redwood, Bart., 4, Bishopsgate, London, E.C., Analyst.
1906. Berry, Arthur J., 14, Regent Street, Cambridge, Chemist.
1883. Berry, E. E., Bordighera, Italy, and (Jourole c/o C. H. Grinling, 17, Rectory Place, Woolwich, S.E., Technical Chemist.
1913. Berry, Prof. R. A., The Agricultural College, Blythswood Square, Glasgow, Prof. of Agric. Chemistry.
1903. Berry, W. G., 200, Claremont Avenue, Manhattan, New York City, U.S.A., Chemist.
1909. Beekow, K. J., Södra Storgatan 19, Helsingborg, Sweden, Head Engineer.
1914. Best, Ronald L., 55, Derwent Road, Palmer's Green, London, N., Analytical Chemist.
1886. Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
1914. Bettsworth, A. E. A., 394, St. Paul Street West, Montreal, Canada, Managing Director.
1901. Betts, Anson G., Box 792, Ashville, N.C., U.S.A., Chemist.
- O.M. Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C.; Journals to c/o The Viscose Development Co., Pembroke Road, Bromley; Public Analyst and Consulting Chemist.
1900. Bevan, Jno. W., Morriston Spelter Works, Morriston, R.S.O., Glamorgan, Manager of Metallurgical Works.
- O.M. Beveridge, Jas., Springfield House, Chatham, N.B., Canada, Pulp and Paper Manufacturer.
1909. Bewick, R. M., "Lynton," Park West, Hcswall, Cheshire, Traveller.
1916. Beynon, D. E., 80, Hogarth Avenue, Toronto, Canada, Rubber Chemist.
1896. Bibby, John, c/o J. Bibby and Sons, Formby Street, Liverpool, Chemist.
- O.M. Biekerdike, W. E., Bryers Croft, Wiltshire, near Blackburn, Manufacturing Chemist.
1907. Bickerstaffe, Robert, 10, Abbey Street, Carlisle, Chemist.
1903. Bierwith, L. W., c/o Du Pont Powder Co., Haskell, N.J., U.S.A., Civil Engineer.
1910. Bigelow, Chas. A., c/o Actna Explosive Co., 120, Broadway, New York, U.S.A., Superintendent.
1912. Bigelow, Edward P., Mellin's Food Library, 291, Atlantic Avenue, Boston, Mass., U.S.A., Chemist.
1884. Biggart, J. Wm., 29, Cathcart Street, Greenock, Scotland, Analytical Chemist.
1891. Biggart, Wm. L., Rossarden, Kilmacolm, Scotland, Public Analyst.
1911. Biggins, J. E., c/o Gulf Refining Co., Port Arthur, Texas, U.S.A., Chemist.
1910. Biggs, J. W. H., 326, High Street, Plumstead, S.E., Chemist.
- O.M. Billing, H. S., 42, Kingsley Road, Mutley, Plymouth, Chemist.
1896. Billington, Chas., Heimath, Porthill, Longport Staffordshire, Metallurgist.
1911. Bingham, H. C., 7, Gracechurch Street, London, E.C., Consulting Engineer.
1917. Birch, Allen E. W., Kimberley Reefs Gold Mine, Bindura, Rhodesia, Cyanide Manager.
1907. Bird, Charles S., jun., Messrs. F. W. Bird and Son, Library Dept., East Walpole, Mass., U.S.A., Paper Maker.
1895. Bird, Wm. R., (communications) 125, Goddard Avenue; (Journals) Laboratory, G.W.R. Works, Swindon, Wilts., Analytical Chemist.
1902. Bird, W. Robt., 217, Newport Road, Cardiff, Oil Merchant.
1915. Birley, J. Harold, c/o Chas. Macintosh and Co., Ltd., Cambridge Street, Manchester, Indianrubber Manufacturer.
1883. Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, E., Manufacturing Chemist.
1884. Bishop, Fred., c/o Burmah Oil Co., P.O. Box 67, Rangoon, Burmah, Technical Chemist.
1903. Bishop, Howard E., 119, Pierce Street, Easton, Pa., U.S.A., Chemist.
1903. Bishop, J. T. F., Manchester Chemical Club, Victoria Hotel, Manchester, Secretary.
1905. Bixby, Willard G., 46th Street and 2nd Avenue, Brooklyn, N.Y., U.S.A., Blacking Manufacturer.
1905. Bjerregaard, A. P., P.O. Box 676, Bedford, Ohio, U.S.A., Varnish Chemist.
1912. Björnström Steffanson, G., Hovedpostkontoret, Kristiania, Norway, Pulp and Paper Works Manager.
1909. Blacher, Prof. Charles, L'Ecole Technique de Mescow, Russia, Chemical Engineer.
1904. Black, J. Wyelf, 62, Falcon Avenue, Edinburgh, Analytical Chemist.
1902. Black, W. Geoffrey, Morningthorpe, Mount Pleasant, Norwich, Chemist.
1910. Blackie, Archibald, 223, James Street, Winnipeg, Canada, Chemist.
1894. Blackmore, H. S., P.O. Box 145, Mount Vernon, N.Y., U.S.A., Industrial Chemist.
1896. Blagden, Victor, 4, Lloyd's Avenue, London, E.C., Chemical Merchant.
1883. Blagden, W. G., 245, Preston Road, Brighton, Chemical Merchant.
1897. Blair, Andrew A., 406, Locust Street, Philadelphia, Pa., U.S.A., Analytical Chemist.

1915. Blake, Azel F., Atlantic Sugar Refineries, Ltd., St. John, New Brunswick, Canada, Chief Chemist.
1884. Blake, Jas., Thames Sugar Refinery, Silvertown, London, E., Manager.
1910. Blakeley, A. G., P. and R. Coal and Iron Co., Pottsville, Pa., U.S.A., Chemist.
1893. Blears, John, c/o Langworthy Bros. and Co., Ltd., Greengate Mills, Salford, Dyer and Calico Printer.
1908. Blichfeldt, S. H., Vine Cottage, Southall, Middlesex, Bacteriologist and Fermentation Chemist.
1905. Bliss, H. J. W., United University Club, Pall Mall East, London, S.W., Chemist.
1916. Bloch, J. J., 85, Deansgate Arcade, Manchester, Chemist.
1889. Bloed, Victor G., Station D., Baltimore Md., U.S.A., Manufacturing Chemist.
1908. Blomeley, Adam Y., c/o Arbuckle Bros. Sugar Refinery, Brooklyn, N.Y., U.S.A., Chemist.
1916. Blondel, Paul, La Revue des Produits Chimiques, 196, rue La Fayette, Paris, France, Director and Proprietor.
1891. Bloomer, Fred J., Penpont, Clydach, R.S.O., Glamorgan, Nickel Works Manager.
1886. Blount, Bertram, Laboratory, 76 and 78, York Street, Westminster, S.W., Analytical Chemist.
1888. Bloxam, A. G., 29, Southampton Buildings, Chancery Lane, London, W.C., Chemist and Patent Agent.
1916. Bluman, Nicholas J., Ceylon House, 49-51, Eastcheap, London, E.C., Chemical Engineer.
1903. Blumenthal, Lionel. See Blundell, Lionel.
1903. Blundell, Lionel, Hill-side, Prestwich Park, Manchester, Managing Director.
1886. Blundstone, E. R., 79, York Street, Westminster, S.W., Consulting Chemist.
1906. Blyth, M. Wynter, Lacton House, Tankersley near Beamsley, Yorks. Analytical and Consulting Chemist.
1908. Blythe, Jas. R., Craiglea, Aulcoshaw near Manchester, Leather Trades Chemist.
- O.M. Boake, A., Watton Road, Stratford, E., Manufacturing Chemist.
1888. Boake, Edmund J., Witford Lodge, Chelmsford, Essex, Manufacturing Chemist.
1912. Boan, Robt., Laboratory, Government Railway Offices, Spencer Street, Melbourne, Vic., Australia, Engineer-in-charge.
1915. Boardman, Fred., 58, King William Street, Greenwich, S.E., Metallurgical Chemist.
1899. Boehm, Fred., 16, Jewry Street, London, E.C., Chemical Agent and Merchant.
1910. Boehringer, Dr. R., Essex and First Streets, Harrison, N.J., U.S.A., Chemist.
1898. Bogert, Prof. Marston T., Department of Organic Chemistry, Columbia University, New York City, U.S.A., Professor of Organic Chemistry.
1915. Boiling, E. H., 6, Leyland Road, New Cross, S.E., Analytical and Research Chemist.
1903. Bo'am, Dr. H. W., Queen Margaret College, Glasgow, Lecturer on Chemistry.
1909. Bolden, Wm., Dalmellington Iron Works, Dunaskin, Ayrshire, Chemist.
1916. Bolsover, G. R., 31, Rossington Road, Brocco Bank, Sheffield, Metallurgist.
1901. Bolton, E. Richards, 46, Stamford Brook Road, Hammersmith, W., Manufacturing Chemist.
1905. Bond, John, Crowlands, Southport, Engineer.
1905. Bond, Josiah, Alto, Arizona, U.S.A., Mining Engineer.
1912. Bone, S. C., 30, Long Lane, Garston, Liverpool, Chemical Works Manager.
1905. Bone, Prof. W. A., F.R.S., "Montrose," Harpenden Road, St. Albans, Herts, Professor of Chemical Technology.
1917. Bonnyman, Jas S., 134, Cambridge Drive, Kelvin-side N., Glasgow, Analytical Chemist.
1892. Bookman, Dr. S., 48, East 82nd Street, New York City, U.S.A., Chemist.
1914. Boon, Dr. A. Archibald, Chemistry Dept., Heriot Watt College, and (Juls.) 87, Warrander Park Road, Edinburgh, Assistant Professor of Chemistry.
1888. Boor, Leonard G., 21, Mincing Lane, London, E.C., Chemical Merchant.
1912. Boorne, Wm. H., Bush Lane House, Cannon Street, London, E.C., Metallurgist.
1916. Booth, Jas., jun., 99, Gawthorne Street, New Basford, Nottingham, Chemist.
1908. Booth, Jos. W., George E. Kunhardt Mills, Lawrence, Mass., U.S.A., Superintendent.
1904. Booth, N. Parr, Laboratory, Cadbury Bros., Ltd., Bourneville, near Birmingham, Chemist.
1916. Boothman, John, Oak Villas, Whitley Bridge, S.O., Yorks, Works Chemist.
1903. Boral, Robin, Rhodes Mount, Rhodes, near Manchester, Works Manager.
1897. Borland, C. R., Concord, Mass., U.S.A., Smokeless Powder Manufacturer.
- O.M. Borland, W. D., Beacon Lodge, Bean. *via* Dartford, Kent, Manufacturer of Explosives.
1908. Bose, R., 92-95, Upper Circular Road, Calcutta, India, Chemical Works Manager.
1890. Bost, W. D. Ashton, Cartvale Chemical Works, Paisley, Chemical Manufacturer.
1912. Boswell, Maitland C., Chemistry and Mining Building, University of Toronto, Canada, Lecturer on Organic Chemistry.
- O.M. Bothamley, C. H., Weston-super-Mare, Somerset, County Director of Technical Instruction.
1890. Bott, Dr. W. Norman. See Norman-Bott, Dr. W.
1901. Bottomley, Dr. J. Frank, c/o The Thermal Syndicate, Ltd., Neptune Road, Wallsend-on-Tyne (Journals to Kearsney, Westfield Avenue, Gosforth, Newcastle-on-Tyne), Consulting Chemist.
1906. Bottomley, W., c/o The United Alkali Co., Ltd., Chief Engineer's Office, Widnes, Chief Engineer.
1915. Boulter, E. C., 113, Lawrence Road, Wavertree, Liverpool, Chemist.
- O.M. Boulton, H. E., (Journals to c/o Messrs. Burt, Boulton and Haywood Ltd., Totton, near Southampton), Chemical Manufacturer.
- O.M. Boulton, Sir Samuel B., Bart., 64, Cannon Street, London, E.C. (Journals to c/o Burt, Boulton & Haywood, Ltd., Latresne (Gironde), France), Chemical Manufacturer.
1883. Boulton, T. S., 14, Freegrove Road, Caledonian Road, London, N., Manager.
1905. Bourne, Lyman, M., 210, Waterman Street, Providence, R.I., U.S.A., Chemist.
1917. Bousquet, Calixte F., 130, Laval Avenue, Montreal, Canada, Chief Chemist.
1888. Bower, Frank, Brewery House, Spitalfields, E., Analytical Chemist.
1909. Bower, Joshua, c/o Kynoch, Ltd., Lion Works Wotton, Birmingham; Journals to 45, St. Peter's Road, Handsworth, Birmingham, Chemist.
1897. Bower, Wm. H., 29th Street and Gray's Ferry Road Philadelphia, Pa., U.S.A., Chemical Manufacturer.
1892. Bowes, Harry, 9, Park Road, Heaton Moor, Stockport, Analytical Chemist.
1915. Bowis, Dr. H. J., 9, Rectory Road, West Bridgford, Nottingham, Technical Chemist.
1883. Bowley, Jos. John, Wellington Works, Battersea Bridge, London, S.W., Chemical Manufacturer.
1899. Bowley, J. Plunkett (retain Journals), Varnish Manufacturer.
1908. Bowman, Fred C., 1632, University Avenue, New York City, U.S.A., Chemist.
1884. Bowman, R., c/o Bowman's Ltd., Moss Bank Works, Widnes, Chemical Manufacturer.
1907. Bowman, Richard S., Quarr Cottage, Great Sankey, near Warrington, Chemist.
1896. Bowman, Walker, 39, Cortlandt Street, New York City, U.S.A., Chemist.
1917. Bowyer, John J., 41, Heath Road, Runcorn, Cheshire, Chemist.
1904. Boyce, Framroze H., 86, Hugh's Road, Chaupaty, Bombay, India, Technical Chemist.
1893. Boyce, Frank, 48, Duchy Road, Harrogate, Technical Chemist.

1910. Boyce, James, Route 8, Holland, Mich., U.S.A., Chief Chemist.
1913. Boyd, Robert, c/o British Columbia Sugar Refining Co., Ltd., Vancouver, B.C., Canada, Chemist.
1885. Bradburn, J. A., 311, Montgomery Street, Syracuse, N.Y., U.S.A., Manufacturing Chemist.
1912. Bradford, Francis L. W., 109, Rotton Park Road, Edgbaston, Birmingham, Chemist and Works Manager.
1895. Bradford, Henry, Strettington, Goodwood, near Chichester, Analytical Chemist.
1915. Bradley, G. W. J., By-Products Dept., The Ebbw Vale Steel, Iron and Coal Co., Ltd., Ebbw Vale, Mon., Chemist.
1917. Bradshaw, Hamilton, Experimental Station, Henry Clay, Del., U.S.A., Director.
1917. Brady, Dr. Oscar L., 10, Blonden Terrace, Plumstead, S.E., Research Chemist.
1896. Bragg, Everett B., 1838, Chicago Avenue, Evanston, Ill., U.S.A., Manufacturing Chemist.
1891. Braithwaite, Isaac, Ghyll Close, Kendal, Westmoreland, Drysalter.
1897. Braithwaite, Jno. O., Holme Lacey, Warren Road, Chingford, Essex, Pharmaceutical Research Chemist.
1903. Brame, Prof. J. S. S., 3, Vanbrugh Fields, Blackheath, S.E., Professor of Chemistry.
- O.M. Bramham, W., Bank Chambers, 300, Mare Street, Hackney, N.E., Chemical Engineer.
1902. Brangan, Jas. Aug., 12, Park Avenue, Millbourne, Delaware Co., Pa., U.S.A., Chemical Salesman.
1915. Branson, F. H., 14, Commercial Street, Leeds, Manufacturing Chemist.
- O.M. Branson, F. W., Wynneholme, Far Headingley, Leeds, Pharmaceutical Chemist.
1903. Brassard, Fred A., 46, Viciar Lane, Bradford, Yorks, Aniline Dyestuff Importer.
1901. Brearley, Harry, c/o The Amalgams Co., Ltd., Attercliffe Road, Sheffield, Analytical Chemist.
1906. Breckenridge, John E., American Agricultural Chemical Co., Carteret, N.J., U.S.A., Chemist.
1917. Breithaupt, J. Edward, c/o The Breithaupt Leather Co., Kitchener, Ont., Canada, Chemical Engineer.
1900. Brewis, E. T., 31, Belgrave Road, Leyton, E., Analytical Chemist.
1894. Breyer, Theodor, 725, Washington Avenue, Wilmette, Ill., U.S.A., Chemist.
1916. Briant, Arthur, Fern Villa, Helsby, Cheshire, Works Chemist.
1885. Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.
1916. Brierley, Michael, c/o Anseo Co., Research Laboratory, Binghamton, N.Y., U.S.A., Chemist.
1890. Brierley, J. T., Highfield, Golden Hill, Leyland, near Preston, Lancs., Analytical Chemist.
1893. Briggs, J. F., 3, Hartington Street, Derby, Technical Chemist.
1912. Briggs, Capt. O. W. H., c/o Harborough Rubber Co., Market Harborough, Chemist.
1885. Briggs, T. Lynton, 188, Central Avenue, Flushing, Long Island, N.Y., U.S.A., Technical Chemist.
1917. Brightman, R., Price's Co., Ltd., Belvedere, Kent, Research Chemist.
1914. Brinsley, Frank, 9, Crowthorn Road, Ashton-under-Lyne, Demonstrator in Physical Chemistry.
1910. Brisbane, James W., H.M. Works, Queensferry, Chester, Analytical Chemist.
1917. Briscoe, H. V. A., 40, Cyril Mansions, Prince of Wales Road, Battersea Park, S.W., Consulting Chemist.
1905. Bristol, Dr. H. Stanley, c/o Fibre Finishing Co., Greendale, Worcester, Mass., U.S.A., Chemist.
1886. Bristow, G. W., c/o Walter J. Crook, 10, Eastcheap, London, E.C., Chemical Manager.
1912. Britland, Wm. J., Pear Tree Cottage, Alvanley, near Helsby, Cheshire, Chemist.
1917. Britton, Reginald P. L., 58, The Crescent, Wimbledon Park, London, S.W.
1887. Broadbent, H., c/o Goodall, Backhouse and Co., Sovereign Street, Leeds, Chemist.
1889. Breck, Arthur, Firework Factory, Sutton, Surrey, Firework Manufacturer.
1910. Brodribb, Noel K., Cordite Factory, Ascot, Vale, Melbourne, Victoria, Australia, Chemist.
1912. Bromley, Henry S., 1000, Wissahickon Avenue, Mount Airy, Philadelphia, Pa., U.S.A., Lace Manufacturer.
1896. Brooke, C. B., jun., Colna House, Brantham, near Manningtree, Xylonite Manufacturer.
1900. Brooke, Jno. R., Government Opium Factory Singapore, S.S., Superintendent.
1884. Brookes, E. A., c/o Braden Copper Co., Ltd., Sewell Rancagua, Chile, Chemist.
1916. Brooks, Prof. B. T., 593, Cardon Road, Westfield, N.J., U.S.A., Prof. of Chemical Engineering.
1906. Brooks, Cecil J., c/o M. M. Siman, Benkoelen, Sumatra, Ned. India, Metallurgist.
1916. Brot, Dr. Maurice, Oleum Works, La Rochelle, France, Consulting Chemist.
1911. Brothers, Horace E., Higher Knutsford Road, Latchford, Warrington, H.M. Inspector of Factories.
1909. Brothers, Wm., Meadow House, Tunstead Milton, near Whaley Bridge, Derbyshire, Chemical Manufacturer.
- O.M. Brotherton, Colonel E. A., City Chambers, Leeds, Ammonia Distiller.
1884. Brown, Prof. A. Crum, F.R.S., 8, Belgrave Crescent Edinburgh, Professor of Chemistry.
1905. Brown, Prof. Adrian J., Kinside, West Heath Road, Northfield, near Birmingham, Professor of Brewing.
1902. Brown, A. H. M., 133, Kent Street, London, Ont., Canada, Metallurgist.
1891. Brown, Caesar R., 141, Victoria Avenue, Prittlewell, near Southend, Works Foreman.
- O.M. Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
- O.M. Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.
1890. Brown, Edw. Hilton, c/o N. 12, Aptakers Prospect, Petrograd, Russia, Analytical Chemist.
1894. Brown, Geo. E., c/o "The British Journal of Photography," 24, Wellington Street, Strand, London, W.C., Chemist.
1910. Brown, Geo. Winslow, Assabet Mills, Maynard, Mass., U.S.A., Chemist.
- O.M. Brown, Henry, Benskins Brewery, Watford, Herts., Brewing Chemist.
1899. Brown, Dr. Henry C., The Chemical Works, King's Lynn, Chemical Manufacturer.
- O.M. Brown, Dr. Horace T., F.R.S., 52, Nevern Square, Kensington, S.W., Brewing Chemist.
1905. Brown, Hugh B., c/o Messrs. Carr, White and Co., Ltd., Wigton, Cumberland.
1917. Brown, Le Roy, 55, Summit Avenue, Sault Ste. Marie, Ontario, Canada, Civil Engineer.
1917. Brown, Norman B., Shawinigan Falls, Quebec, Canada, c/o Shawinigan Electro-Metals Co., Assistant Superintendent and Chemist.
1892. Brown, Reginald B., 45, Finsbury Square, London, E.C., Technical Chemist.
1901. Brown, Samuel B., Marringhurst, Marple, Cheshire, Calico Printer.
1916. Brown, W. F., 2, Flora Villas, Whalebone Avenue, Chadwell Heath, Essex, Gas Works Chemist.
- O.M. Brown, Walter, c/o Jas. H. Dennis and Co., Ltd., Widnes, Technical Chemist.
1900. Brown, Walter B., Victor Chemical Works, 1805, Fisher Building, Chicago, Ill., U.S.A., Chemist and General Superintendent.
1901. Browne, Dr. Arthur L., 215, East Fayette Street, Baltimore, Md., U.S.A., Analytical Chemist.
1906. Browne-Cave, E. J. C. See Cave-Browne-Cave, E. J.
1905. Browning, Prof. K. C., 11, Barton Terrace, Dawlish, S. Devon, Professor of Chemistry.
- O.M. Browning, W., Bentcliffe, Acerington, Calico Printer.
1917. Brownlee, Richard, P., 43, Bloxridge Street, Langley, Birmingham, Technical Chemist.

1902. Brownson, Dr. H. W., King's Norton Metal Co., Ltd., King's Norton, Birmingham, and (Jns.) 109, Oxford Road, Mosely, near Birmingham, Works Chemist.
1902. Bruce, Alex., Laboratory, Hyde Park Corner, Colombo, Ceylon, Chemist.
1911. Bruce, Joseph, Jnls. to General Manager, Dynamite Factory, West Somerset, Cape Colony, Secretary.
1908. Bruce, Robert, 44, High Street, Leven, Fifeshire, Works Chemist.
1900. Bruce, Wm. T., 3, Lombard Court, London, E.C., and (Jnl.) c/o T. C. Allehin, Longfield, Kent, Director.
1911. Brunet, Louis, "Revue Générale des Sciences," 97, Boul. Montmorency, Paris XVI, France, Chemist and Secretary.
1916. Brunjes, Thos., 67, Waller Road, New Cross, S.E., Tar Distillery Chemist.
1894. Brunner, H. Bertram, The Hollies, Hartford, Cheshire, Chemist and Electrician.
1887. Brunner, J. F. L., M.P., c/o Brunner, Mond, and Co., Ltd., Caxton House, Westminster, S.W., Chemical Manufacturer.
- O.M. Brunner, Rt. Hon. Sir J. T., Bart., Silverlands, Chertsey; and (Journals) c/o Brunner, Mond, and Co., Ltd., Northwich, Cheshire, Chemical Manufacturer.
1902. Brunner, Roscoe, The Winnington Hall Club, Winnington, Northwich, Alkali Manufacturer.
1894. Bruntton, J. Dixon, Wire Mill, Musselburgh, Scotland, Wire Manufacturer.
1904. Bryant, Arthur P., c/o Clinton Sugar Refining Co., Clinton, Iowa, U.S.A., Chemist.
1908. Bryce, Chas. C., 43-45, Great Tower Street, London, E.C., Merchant.
1916. Bryce, James, United States Finishing Co., 389, Charles Street, Providence, Rhode Island, U.S.A., Print Works Manager.
1894. Bryce, Thos., Tharsis Mines, Huelva, Spain, Chemist.
1897. Bryson, Jas., Pumpherson Oil Works, Mid-Caldor Scotland, Oil Works Manager.
1892. Buchanan, D. G., 39, Inverness Terrace, Hyde Park, London, W., Analyst.
1908. Buchanan, Duncan G., 27, Woodlawn Avenue East, Toronto, Canada, Chemist (Rubber Works).
1904. Buchanan, E. F., 11432, Prairie Avenue, Chicago, Ill., U.S.A., Chemist.
1888. Buchanan, Jas., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
1904. Buchanan, John L., Braehead, Mill Road, Bromborough, Cheshire, Analytical Chemist.
1904. Buchanan, Joshua D., c/o Nobel's Explosives Co., Ltd., Polmont Station, Scotland, Analyst.
1910. Buchanan, Walter G., c/o Lantaro Nitrate Co., Ltd., Talta, Chile, Chemist.
1897. Buck, Chas. A., Prospect and Park Avenues, Bethlehem, Pa., U.S.A., Chief Chemist (Bethlehem Iron Co.).
1911. Budde, Dr. Carl, 1, Belford Road, Sunderland, Chemical Engineer.
1909. Buell, W. H., c/o Winchester Repeating Arms Co., New Haven, Conn., U.S.A., Chemist.
1915. Bugge, E. R., Instow, Mycenae Road, Blackheath, S.E., Manufacturing Chemist.
1909. Buggy, Thos., Butte, Montana, U.S.A., Assayer and Chemist.
1917. Bull, Bertram A., 14, North Road, West Bridgford, Nottingham, Works Chemist (Boots Pure Drug Co.).
1902. Bull, Irving C., 100, Maiden Lane, New York City, U.S.A., Chemist.
1899. Bult, Herbert J., 63, Addiscombe Road, Croydon, Chemist.
- O.M. Bumby, H., Bellevue, Sandbach, Cheshire, Iron and Chemical Works Director.
1915. Bunce, A., c/o The Morgan Crucible Co., Ltd., Church Road, Battersea, S.W., Works Chemist.
- O.M. Bunker, H. E., 310, Kingston Road, Toronto, Ont., Canada, Technical Chemist.
1901. Bunting, Henry H., Oficina de Ensayes F. C. C. del P., Callao, Peru, Analyst.
1893. Burbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
1896. Burford, Samuel F., The Ridgeway, Rothley, near Leicester, Analytical Chemist.
1889. Bürger, Dr. J., 9, Vincent Avenue, Chorlton-cum-Hardy, Manchester, Technical Chemist.
1889. Burgess, Geo., Sydney Cottage, Halebank, Widnes, Chemist.
1901. Burgess, Prof. Chas. F., C. F. Burgess Laboratories, Madison, Wis., U.S.A., Chemical Engineer.
1889. Burgess, Wm. T., 26, Priory Road, Bedford Park, London, W., Analytical Chemist.
1902. Burkard, Dr. Ernst, Solothurn, Switzerland, Chemist.
1917. Burke, Henry U., c/o The British American Tobacco Co., Ltd., Ashton Gate, Bristol, Works Manager.
1891. Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks, Sulphuric Acid Maker.
1897. Burnet, Sir Jno. Jas., 18, University Avenue, Glasgow, and (Journals) 1, Montague Place, Bedford Square, London, W.C., Architect.
1909. Burnett, Arthur, The Haven, Buxton Road, Chinley, Derbyshire.
1893. Burnham, J. C., Analytical Chemist.
1900. Burr, Edmund C., 1722, Vallejo Street, San Francisco, Cal., U.S.A., Manufacturer.
1917. Burr, Richard J., 247, Browning Road, Manor Park, Essex, Works Chemist.
- O.M. Burrell, B. A., 8, Springfield Mount, Leeds, Analytical Chemist.
1910. Burrell, Keith, Burrell's Wharf, Millwall, London, E., Manufacturer.
1906. Burrough, Ernest J., Cale Distillery, Hutton Road, Lambeth, S.E., Rectifier.
1912. Burt-Gerrans, J. T., 46, Dewson Street, Toronto, Canada, Electro-Chemist.
1901. Burton, A.H., Canadian Dyers' Association, Ltd., 2-16, Liberty Street, Toronto, Canada, Dyer and Finisher.
1914. Burton, Donald, Westbourne, St. Andrew's Avenue, Morley, near Leeds, Research Assistant.
1903. Burton, Jno., 2, Green Street, Bethnal Green, E., Dye and Chemical Manufacturer.
1911. Burton, Tom F., "Manna Mead," Upper Warlingham, Surrey, Editor.
1904. Burton, T. E., c/o Scott, Greenwood, and Son, 8, Broadway, Ludgate Hill, London, E.C., Technical Journalist.
1889. Burton, Wm., Carisbrook, Park Crescent, Victoria Park, Manchester, Potter's Chemist.
1915. Bury, Ernest, Skinningrove Iron Co., Ltd., Carlin How S.O., Yorks, Works Manager.
1906. Busby, Fred. E., Arnold Print Works, North Adams, Mass., U.S.A., Chemist.
1913. Bush, Dr. Harry T., 7, Gracechurch Street, London, E.C., Chemical Engineer.
1897. Bush, J. M., c/o W. J. Bush and Co., Ltd., Ash Grove, Hackney, E., Manufacturing Chemist.
1897. Butler, David B., 6, Earl Street, Westminster, S.W., Cement Expert.
1913. Butler, Geo. B., Adelaide Villa, Belle Vue Grove, Grove Hill, Middlesbrough, Assistant Blast Furnace Manager.
1890. Butler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
1885. Butler, Samuel, The Cedars, Compton, Wolverhampton, Brewer.
1905. Butler, Dr. T. H., c/o Wm. Butler and Co., Ltd., Crews Hole, Bristol, Chemist (Tar and Rosin Distillery).
1886. Butler, W. W., c/o Mitchells & Butlers, Ltd., The Brewery Library, Cape Hill, Birmingham, Brewer.
1892. Butterfield, W. J. A., 66, Victoria Street, Westminster, S.W., Analytical Chemist.

1897. Butters, Charles, 54, New Broad Street, London, E.C., and (Journals) 6272, Chabot Road, Oakland, Cal., U.S.A., Metallurgist.
1900. Butterworth, Elwell R., c/o Reversible Collar Co., 111, Putnam Avenue, Cambridge, Mass., U.S.A., Chemist.
- O.M. Byard, A. G., c/o Burt, Boulton, and Haywood, Apartado 8, Bilbao, Spain. Technical Chemist.
1905. Byrne, F. A., 2, Ludgate Hill, Birmingham, Director of Chemical Co.
1893. Byrom, T. H., 58, Hornsey Rise, Upper Holloway, London, N., Analytical Chemist.
1915. Bywaters, H. W., 9, Henleaze Avenue, Bristol, Chemist.
- C
1884. Cabot, Godfrey L., 940, Old South Building, Boston, Mass., U.S.A., Manufacturing Chemist.
1907. Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Caddick, Arthur, Casa Fundición, Miras de Río Tinto, Huelva, Spain. Works Chemist.
1889. Cadett, Jas., Ashtead, Surrey, Chemical Engineer.
1905. Cain, Dr. J. C., 24, Aylestone Avenue, Brondesbury Park, N.W., Colour Chemist.
1891. Caines, G. S. A., 68, Hilldrop Crescent, Camden Road, London, N.W., Analytical Chemist.
1917. Calam, Harold, 18, Melton Road, West Bridgford, Nottingham. Research Chemist (Boots Pure Drug Co.).
1905. Calder, Prof. Edwin E., Long Meadow R.I., U.S.A., Professor of Chemistry.
1897. Calder, W. A. S., 449, Hagley Road, Birmingham, Chemical Manufacturer.
1912. Caldwell, Wallace, L., Apartment "F," Fitzgerald Apartment, Birmingham, Ala., U.S.A., Engineering Chemist.
1888. Caldwell, Wm., Murray Street, Paisley, Scotland, Drysalter.
1917. Caley, John, Premier Oil Extracting Mills, Ltd., Hull, Managing Director.
1912. Callan, Dr. Thomas, 2, Spring Bank, Crumpsall Lane, Higher Crumpsall, Manchester, Technical Chemist.
1902. Calm, Dr. Klas. E., California Club, Los Angeles, Cal., U.S.A., Manufacturing Chemist.
1904. Calvert, Dr. Harry T., Ministry of Munitions, Dept. of Explosives Supplies, Storey's Gate, Westminster, S.W., Chemist.
1895. Cambier, Jacob, 1401, Carteret Avenue, Pueblo, Colo., U.S.A., Chemist.
1916. Cameron, Alex. M., Beechleigh, Lasswade, Midlothian, Analytical Chemist.
1904. Cameron, Walter S., 239, West 136th Street, New York City, U.S.A., Manufacturing Perfumer.
1908. Cameron, Wm., c/o The Asiatic Petroleum Co., Barrow-in-Furness, Asst. Refinery Manager.
- O.M. Cammack, J., "Fernsholme," Preseot Road, St. Helens, Technical Chemist.
1886. Campbell, Andrew, 1, Park Road, Beckenham, Kent, Chemist (Mineral Oil).
1912. Campbell, Arthur F., 9, Fort Road, Sedgley Park, Manchester, Research Chemist.
1908. Campbell, Fred. A., The Working Men's College, Latrobe Street, Melbourne, Victoria, Australia, Principal.
1907. Campbell, John A., c/o British South African Explosives Co., Modderfontein, Transvaal, Analytical Chemist.
1912. Campbell, Kennedy, c/o British Dycwood Co., Ltd., Parkhead, Glasgow, Chemist.
1901. Campbell, Kenneth F., 1, Peel Street, Huddersfield, Civil Engineer.
1911. Campbell, L. E., 5, St. Matthew's Avenue, Surbiton, Surrey, Chemist.
1909. Campbell, Peter, Kearny, N.J., U.S.A., Linoleum Manufacturer.
1915. Campbell, Wm. B., 197, Wilson Avenue, N.D.G., Montreal, Canada.
1911. Campbell, Wm. E., c/o Gutta Percha and Rubber Ltd., O'Hara Avenue, Toronto, Canada, Industrial Chemist.
1914. Camus, Edward C. A., 8, Rue de Mondovi, Paris I., France, Chemical Merchant.
1909. Candee, Chas. N., 39, South Drive, Toronto, Canada, Rubber Manufacturer.
1908. Canning, Ernest R., 137, Great Hampton Street, Birmingham, Manufacturer.
1891. Carden, Albert J., 20—21, Harp Lane, Gt. Tower Street, London, E.C., Distiller.
1917. Carder, Frederick, Stenben Glass Works, Corning, N.Y., U.S.A., Chemist and General Manager.
1915. Cardwell, David, 50, Alexandra Road South, Manchester, S.W., Chemist.
1893. Carey, Arthur, Orient House, Gateacre, Liverpool, Chemist.
1906. Carey, W. Gordon, c/o United Alkali Co., Ltd., Allhusen Works, Gateshead-on-Tyne, Chemist.
1904. Cargill, J. T., c/o Finlay, Fleming, and Co., Rangoon, Burma, East India Merchant.
1915. Carlos, Arthur S., 42, Foxley Road, North Brixton, S.W., Analytical Chemist.
1896. Carmichael, Herbert, Bureau of Mines, Victoria, British Columbia, Public Analyst and Assayer.
1884. Carnody, Prof. Patrick, Lostwithiel, Cornwall, Analytical Chemist.
1897. Carnell, Wm. C., 1141, Arret Street, Frankford, Philadelphia, Pa., U.S.A., Chemist.
1916. Carothers, A., 164, Roseberry Street, St. James, Winnipeg, Canada, Pharmaceutical Chemist.
1893. Carpenter, Dr. C. C., South Metropolitan Gas Co., 709A, Old Kent Road, London, S.E., Civil Engineer.
1908. Carpenter, Edwin P., Culvert Works, Sheepcote Lane, Battersea, S.W., Manager of Cascin, Ltd.
1900. Carpenter, Frank B., 11, South 12th Street, Richmond, Va., U.S.A., Analytical Chemist.
1900. Carpenter, Harry B., c/o Lister's Agricultural Chemical Works, Newark, N.J., U.S.A.
1915. Carpenter, Henry A., R. F. D., No. 3, Sewickley Pa., U.S.A.
1904. Carr, Francis H., Westhorpe, Ruddington, Notts., Manufacturing Chemist.
1917. Carriek, Peter McAl., 329, Railway Street, Vancouver, B.C., Managing Director.
1907. Carrier, C. F., jun., 1567, Lee Street, Charlestown, W. Va., U.S.A., Manufacturing Chemist.
1904. Carter, A., Cuba Street, Petone, Wellington, New Zealand, Works Manager.
1905. Carter, Robert A., 4923, Osage Avenue, Philadelphia, Pa., U.S.A., Chemist.
1917. Carter, Sidney R., The University, Birmingham, Chemistry Lecturer.
1895. Carter, Stewart F., 229, President Street, Passaic, N.J., U.S.A., Technical Chemist.
1903. Carter, Thomas, West End View, Ravensthorpe, Dewsbury, Yorks, Works Chemist.
1886. Carter, W. Chas., c/o Dominion Iron and Steel Co., Sydney, C.E., Canada, Analytical Chemist.
1916. Cartwright, T. T. F., c/o New Explosives Co., Stowmarket, Suffolk, Chemist.
1911. Carty, Ronald D., The Laboratories, Public Works Ministry Gardens, Cairo, Egypt, Analytical Chemist.
1889. Carulla, F. J. R., 84, Rose Hill Street, Derby, Chemical Manufacturer.
1906. Carveth, Dr. H. R., Niagara Electrochemical Co., Niagara Falls, N.Y., U.S.A., Works Manager.
1914. Casey, John V., Charlemont, Moy, Co. Tyrone, Ireland, Waterproof Manufacturer.
1903. Caspari, Dr. W. A., c/o Messrs. Evans, Sons, Lescher, and Webb, Ltd., 60, Bartholomew Close, London, E.C., Chemist and Physicist.
1917. Cass, Wilfred G., Brimstage, Birkenhead, Abstractor.
1899. Castro, J. Paul de, 1, Essex Court, Temple, London, E.C., Barrister-at-Law.

1909. Caulkin, Howard A., "The Glen," Cumberhill Road, Duffield, Derbyshire, Analyst.
1906. Cave-Browne-Cave, E. J., c/o Thos. Ness, Ltd., Littleburn Tar Works, Durham, Works Chemist.
1917. Cave-Browne-Cave, E., 567, Hornby Street, Vancouver, B.C., Canada, Merchant.
1896. Caven, Dr. Robt. M., University College, Nottingham, Lecturer in Chemistry.
1914. Caw, Wm., No. 3 Staff Hostel, Eastriggs, Doonack, Annan, Chemist.
- O.M. Cawley, G., 82, Victoria Street, Westminster, S.W., Chemical Engineer.
- O.M. Cawley, J., 609, Mt. Prospect Avenue, Newark, N.J., U.S.A., Analytical Chemist.
1897. Cawley, Thos. A., British Gelatin Works, Ltd., New Bedford Road, Luton, Gelatin Manufacturer.
1906. Chadsey, Stanley B., 476, Brunswick Avenue, Toronto, Canada, Chemist.
1916. Chadwick, George B., c/o The Paterson Manufacturing Co., Ltd., 172, King Street East, Toronto, Canada, District Manager.
1917. Challenger, Dr. Fredk., The University, Edmund Street, Birmingham, University Lecturer.
1910. Challinor, Richard W., Chemical Laboratory, The Technical College, Sydney, N.S.W., Australia, Teacher of Chemistry.
1894. Chaloner, G. W., 26, Eagle Wharf Road, Hoxton, N., Chemical Manager.
1901. Chamberlain, G. E., 641, West Prairie Avenue, Decatur, Ill., U.S.A., Chemist.
1917. Chamberlain, John, 133, Embleton Road, Lewisham, S.E., Gas Engineer.
1910. Chambliss, Prof. Hardee, c/o Commercial Acid Co.'s Plant, R.F.D. No. 1, East St. Louis, Ill., U.S.A., Assistant Commissioner of Public Health.
- O.M. Chance, A. M., Wolcot, Torquay, Devon, Chemical Manufacturer.
1912. Chance, Clinton F., Messrs. Chance and Hunt, Ltd., Oldbury, near Birmingham, Managing Director.
1909. Chance, Edwin M., 1330, F Street N.W., Washington, D.C., U.S.A., Chemist.
1916. Chance, Kenneth M., British Cyanides Co., Ltd., 49, Queen Victoria Street, London, E.C., Managing Director.
1917. Chandhuri, J. K., Digboi, P.O., Upper Assam, India, Chemist (Assam Oil Co., Ltd.).
- O.M. Chandler, Dr. C. F., 51, East 54th Street, New York City, U.S.A., Professor of Chemistry.
1912. Chandler, Lee L., Research Laboratory, Pittsburgh Plate Glass Co., Creighton, Pa., U.S.A., Assistant.
1893. Chaplin, Dr. Edw. M., Public Analyst's Laboratory, Wakefield, Yorks, Analytical Chemist.
1890. Chapman, A. Chaston, 8, Duke Street, Aldgate, E.C., Public Analyst and Consulting Chemist.
1906. Chapman, Arthur J., Baronsmere, Stanhope Avenue, Church End, Finchley, N., and (Journals) c/o F. Claudet, Ltd., 6 and 7, Coleman Street, London, E.C., Analytical Chemist.
1906. Chapman, E. A., c/o Messrs. Boots Drug Co., Ltd., London Road Branch, Nottingham, Chemist.
- O.M. Chapman, Spencer, 36, Mark Lane, E.C., Chemical Manufacturer.
1894. Charlier, A. C. J., Benyoulin, 154, Worple Road, Wimbledon, S.W., Consulting Chemist.
1915. Charlton, W. W. S., c/o The Cotton Powder Co., Uplees, Faversham, Kent, Manufacturing Chemist.
1917. Charpy, Jean F., 12, Briardale Road, Rock Ferry, Perfumer-Chemist.
1900. Chase, March F., c/o Commercial Acid Co., 1916, Boatmen's Bank Building, St. Louis, Mo., U.S.A., Chemist.
1889. Chase, R. L., Arnold Printworks, North Adams, Mass., U.S.A., Manager.
1898. Chattock, Herbert E., 23, Apsley Road, Clifton, Bristol, Oilcake Manufacturer.
1910. Chattopadhyaya, P. C., 27, Narikeldanga Main Road, Harrison Road P.O., Calcutta, India, Chemist.
1915. Chazan, Simon, 188, Elizabeth Street, Hightown, Manchester, Works Chemist.
1901. Cheetham, Howard, 18, St. Ann Street, Manchester, Chartered Patent Agent.
1894. Cheney, John P., c/o Messrs. Cheney Bros., South Manchester, Conn., U.S.A., Chemist and Silk Manufacturer.
1915. Cheng, Pinzen, West Gate, Kia-ting-Lsien, near Shanghai, China, Analytical Chemist.
1916. Chetwin, H. W., 24-26, Wilson Street, Poplar, E., Manufacturing and Analytical Chemist.
1913. Chiaravaglio, Dr. Dino, Piazza Esquilino 23, Rome, Italy, Director, Explosives Laboratory.
1905. Chick, Oliver, 31, Auckland Road, Cranbrook Park, Ilford, Essex, Analytical Chemist.
1917. Chitty, Charles W., Charlton Mill, Dover, Flour Miller.
1890. Chorley, Jno. C., Bewsey, Oxford Road, Birkdale, Lancs., Analytical Chemist.
1917. Chorley, Percy, "High Cross," Kirkburton, near Huddersfield, Research Chemist.
- O.M. Christie, J., Levenfield, Alexandria, Scotland, Dyer and Printer.
1903. Christie, John, c/o Nobel's Explosives Co., Ltd., Pembrey, South Wales, Analytical Chemist.
1914. Christie, John T., c/o Messrs. John Miller and Co., Sandilands Chemical Works, Aberdeen, Analytical Chemist.
1908. Christie, Malcolm, Hornock Cottages, Coatbridge, Scotland, Analytical Chemist.
1910. Christie, Dr. M. G., c/o The Otto-Hilgenstock Coke Oven Co., Post Office House, Leeds, Assistant General Manager.
1898. Christison, Geo., 2, Kelvinside Gardens Glasgow, Engineer.
1907. Christopher, George, Walkden Works, Verney Road, South Bermondsey, S.E., Consulting Chemist.
1907. Christopher, J. E., Solvay Coke Works, Kirkless, Wigan, Assistant in Charge.
- O.M. Chrystal, W. J., 7, West George Street Glasgow, Chemical Manufacturer.
1908. Chrystall, E. R., c/o Curtis's and Harvey, Ltd., Cliffe at Hoo, Kent, Research Chemist.
1906. Church, Sumner R., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U.S.A., Chemical Engineer.
1907. Churchill, Wm., Corning Glass Works, Corning, N.Y., U.S.A., Chemist.
1915. Chute, Robt. J., 347, Pape Avenue, Toronto, Canada, Manufacturer.
1896. Clafin, Alan A., 176, Federal Street, Boston, Mass., U.S.A., Manufacturing Chemist.
1909. Claffin, Albert W., 190, Waterman Street, Providence, R.I., U.S.A., Manufacturing Druggist.
1917. Clague, Thos. M., 24, Grainger Street West, Newcastle-on-Tyne, Pharmaceutical Chemist.
1900. Clamer, Guillian H., 46, Richmond Street, Philadelphia, Pa., U.S.A., Chemist.
1885. Clanahan, H. C., 79, Mosley Street, Manchester, Chemical Merchant.
1905. Clapp, Geo. A., 49, Federal Street, Boston, Mass., U.S.A., Chemist.
1891. Clapp, Ralph R., c/o B. P. Clapp Ammonia Co., Providence, R.I., U.S.A., Manager.
1889. Clapperton, J., jun., Analytical Chemist.
1916. Clare, Geo. R., 54, York Street, Runcorn, Cheshire, Works Chemist.
1917. Clark, Alexander P., 62, Fernwood Park Avenue, Toronto, Ont., Canada, Chemist.
1913. Clark, A. Stanley, 16, Richmond Hill, Langley Green, near Birmingham, Technical Chemist.
1910. Clark, Arthur W., c/o Heath and Milligan Manufacturing Co., 1832, South Canal Street, Chicago, Ill., U.S.A., Superintendent.
1904. Clark, Arthur Wayne, c/o Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemist and Bacteriologist.
1908. Clark, Chas. T., 1303, Sixth Street, Bay City, Mich., U.S.A., Manufacturing Chemist.
1913. Clark, Francis W., 43, Braemar Avenue, Wood Green, London, N., Chemist.

1917. Clark, Prof. Friend E., West Virginia University, Morgantown, W. Va., U.S.A., Prof. of Chemistry.
1910. Clark, Henry, 24, Eastcheap, London, E.C., Oil Refiner.
1900. Clark, Jno., Broadway Works, Millwall Docks, London, E., Manufacturing Chemist.
1916. Clark, John A., Scottish Co-operative Flour Mills, and 11, Walmer Terrace, Ibrox, Glasgow, Analyst.
1906. Clark, M. H., c/o Goodyear's Metallic Rubber Shoe Co., Naugatuck, Conn., U.S.A., Chemist.
1916. Clark, Dr. Robt. H., University of British Columbia, Vancouver, B.C., Canada, Professor of Chemistry.
1902. Clark, Robt. M., 138, Bath Street, Glasgow, Chemist.
1915. Clark, T. W. Firth, "Tilehurst," Pollard Road, Mitcham, Surrey, Technical Chemist.
1906. Clark, Wm. B., Larkfield, Earlestown, Lancashire, Chemist.
1907. Clark, Wm. H., 26, Barry Street, Dunston-on-Tyne, Analytical Chemist.
1912. Clark, William M., Euclid Glass Division, East 152nd Street, Cleveland, Ohio, U.S.A., Chemist.
1908. Clarke, Arthur F., c/o White's South Africa Cement Co., Ventersburg Road, Orange Colony, South Africa, Analytical Chemist.
1916. Clarke, Thos. C., 111, Broadway, New York City, U.S.A., Metallurgical Engineer.
1897. Clarke, Wm. B., c/o Edison-Swan Electric Co., Ltd., Ponders End, S.O. Middlesex, Electro-Chemist.
1889. Claus, Wm. H., c/o Claus and Co., Ltd., Clayton, Manchester, Manufacturing Chemist.
1909. Clayton, Ellis, 3, Princess Gardens, Marino, near Belfast, Lecturer on Bleaching, Dyeing, and Printing.
1895. Clayton, Dr. G. C., c/o The United Alkali Co., Ltd., 30, James Street, Liverpool.
1894. Clayton, Robt. H., 1, Parkfield Road, Didsbury, Manchester, Chemist.
1910. Clayton, Will, Cliffe House, Accrington, Works Chemist.
1905. Clayton, W. E., Admiralty Victualling Yard Grangemouth, Scotland, Superintendent.
1917. Cleghorn, Andrew T., 2657, 2nd Avenue West, Vancouver, B.C., Manufacturing Chemist.
1907. Clement, Leonard, 11, Agnew Street, Lytham, Lanes., Chemist.
1917. Clements, Percy J. N., c/o J. S. MacArthur, Ltd., Loch Lomond Radium Works, Balloch, Dumbartonshire.
1893. Clemes, J. H., 111, Mount Wise, Newquay, Cornwall, S.E.; retain Journals; Chemist.
1905. Clepton, Thos. J., 285, Congress Street, Boston, Mass, U.S.A., Manager (A. Klipstein and Co.).
1915. Clibborn, John W., 12, Weirwood Park, Baillieston Glasgow, Assistant Works Manager.
1906. Clifford, Jos., Laboratories, Public Works Ministry Gardens, Cairo, Egypt, Chemist.
1913. Clifford, Sydney G., 51, Peak Hill, Sydenham, S.E., Analytical Chemist.
1900. Clifford, Wm., Sewage Outfall Works, Wolverhampton, Sewage Works Manager.
- O.M. Clond, T. C., 20, Bucklersbury, London, E.C., Metallurgist.
- O.M. Clowes, Dr. F., The Grange, College Road, Dulwich, S.E.; retain Journals; Chemist.
1891. Clutton, J. H., Fonderie Mines de l'Aude, Villanière par La Cour (Aude), France, Metallurgist.
1911. Clymer, Wm. R., Publicity Department, National Carbon Co., Cleveland, Ohio, U.S.A., Manager.
1899. Coates, Chas. E., jun., Louisiana State University, Baton Rouge, La., U.S.A., Professor of Chemistry.
1917. Coates, H. B., No. 2 Staff Quarters, East Riggs Township, Annap, Chemist.
1911. Coates, Jos. E., c/o Thos. Tyrer & Co., Stirling Chemical Works, Stratford, E., Lecturer.
1888. Coats, John T., 105, Broughton Street, Edinburgh, Manufacturing Chemist.
1915. Cobb, Ernest B., c/o Standard Oil Co. (N.J.), Bayonne, New Jersey, U.S.A.
1893. Cobb, Prof. Jno. W., The University, Leeds, Prof. of Coal Gas and Fuel Industries.
1891. Coblentz, Dr. Virgil, c/o Chemists' Club, 52, East 41st Street, New York City, U.S.A., Research Chemist.
1899. Cochran, Alfred, 559, Madison Street, Brooklyn, N.Y., U.S.A., Chemist.
1901. Cockburn, John A., Mayville, Stevenston, Ayrshire, Analytical Chemist.
1902. Cocking, Allan T., c/o Kynoch, Ltd., Lion Works, Witton, Birmingham, Ammunition Manufacturer.
1905. Coes, Chas. S., 1024, East River Street, Hyde Park, Mass., U.S.A., Oil Chemist.
1903. Coggeshall, Dr. G. W., 2229, California Street, Washington, D.C., U.S.A., Chemical Engineer.
1887. Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
1884. Cogswell, W. B., Syracuse, N.Y., U.S.A., Chemical Engineer.
1915. Cohen, A. M., 19, Wyndcote Road, Mossley Hill, Liverpool, Chemist.
- O.M. Cohen, Dr. J. B., 1, North Grange Mount, Headingley, Leeds, Professor of Organic Chemistry.
1897. Cohn, Alfred I., *See* Cone, Alfred I.
1901. Cohn, Sigmond, 13, Dutch Street, New York City, U.S.A., Metallurgical Chemist.
1901. Cohoe, Prof. W. P., 50, East 41st Street, New York City, U.S.A., Professor of Chemistry.
1891. Colby, Albert L., 447, Lehigh Street, South Bethlehem, Pa., U.S.A., Metallurgical Engineer.
1899. Colby, E. A., Baker Platinum Works, Newark, N.J., U.S.A., Metallurgical Chemist.
- O.M. Colby, W. H., 80, Coldharbour Road, Redland, Bristol.
1917. Cole, Douglas S., Explosives Dept., Imperial Munitions Board, Ottawa, Canada, Chemical Engineer.
1917. Cole, Fredk. C. P., 22, Adelphi Road, Wellfield, Huddersfield.
1916. Coleman, H. S., 3, Wyndham Road, Edgbaston, Birmingham, Electro-Chemist.
1893. Coleman, W. H., 1, Athole Gardens, Newlands, Glasgow, Chemical Engineer.
1916. Coles, Leonard A., Ludlow House, Wakefield Road, Huddersfield, Works Chemist.
1915. Coloy, H. Edwin, 6, Bury Court, St. Mary Axe, E.C., Chemical Manufacturer.
1913. Colgate, R. T., 25, Denmark Road, Reading, Works Chemist.
1905. Collett, John H., Sunnycroft, Tuffley, Gloucester, and (Juls.) The Librarian, Free Library, Gloucester, Chemical Manufacturer.
1887. Collett, J. M., Wynstone Place, Brookthorpe, Gloucester, Chemical Manufacturer.
1908. Collier, F. C., Inland Revenue Laboratory, 317, Queen Street, Ottawa, Canada, Analytical Chemist.
1903. Collier, Pierre, Companhia Industrial Pernambucana, Pernambuco, Brazil, Civil Engineer.
1893. Collin, Dr. C. A., Ferguslie Threadworks, Paisley, Textile Chemist.
1913. Collinge, H. G., Rua Tenente Costa 183, Todos os Santos, Rio de Janeiro, Brazil, Technical Chemist.
1898. Collingridge, Frank, Highstone, New Road, Llanelly, South Wales, Chemist.
1899. Collins, S. Hoare, 9, Cavendish Place, Newcastle-on-Tyne, Agricultural Chemist.
1888. Collins, W. Hepworth. *See* Hepworth Collins, W.
1913. Collinson, R. W., c/o Messrs. J. and J. Colman, Ltd., Starch Dept., Carrow Works, Norwich, Starch Manufacturer.
1899. Collis, Walter F., 12, St. Peter's Road, Harborne, Birmingham, Chemist.
1910. Collitt, Bernard, 15, Massey Road, Lincoln (Journals to Chemical Laboratory, Ruston, Proctor and Co., Ltd., Lincoln), Chemist.
1910. Colman, Fred. J., c/o Brotherton and Co., Ltd., Wear Tar Works, Sunderland, Tar Works Chemist.
1891. Colman, Dr. H. G., Woodthorpe, New Malden, Surrey, Analytical Chemist.
1892. Colquhoun, Ludovic, Dynamite Factory, Modderfontein, Transvaal, Analytical Chemist.

1894. Colquhoun, W., Endcliffe, Endcliffe Crescent, Sheffield, Engineer.
1901. Colwell, J. Kearn, Finsbury Town Hall, Rosebery Avenue, E.C., Analytical and Consulting Chemist.
1906. Comber, A. W., 23, Courtenay Gardens, Upminster, Essex, Metallurgical Chemist.
1917. Comber, Capt., Norman M., No. 2 Training Reserve Battalion, Rugeley Camp, Staffordshire, Lecturer in Agricultural Chemistry.
1900. Comey, Dr. Arthur M., Upland Avenue, opposite Summit Street, Chester, Pa., U.S.A., Technical Chemist.
1911. Comey, Robert H., Wenonah, N.J., U.S.A., Bleacher.
1906. Compton, Miss N. J., Library, University of Nebraska, Lincoln, Neb., U.S.A., Librarian.
1897. Cone, Alfred L., "Edorado," 302, Central Park West, New York City, U.S.A., Chemist.
1901. Connah, Jas., Laboratory, Custom House, London, E.C., Government Analyst.
1891. Conradson, Pontus H., Galena Oil Works, Franklin, Pa., U.S.A., Analytical Chemist.
1889. Conroy, Dr. Jas. T., 9, The Serpentine, Grassendale, Liverpool, Chemist.
1887. Constable, W. H., Australian Alum Works, Runcorn, Analytical Chemist.
1909. Cook, E. Bernard, 23, Cross Street, Finsbury, London, E.C., Manufacturing Chemist.
- O.M. Cook, H. J., The Firs, Woodford Green, Essex, Soap Manufacturer.
1903. Cook, Jas. W., London and Provincial Dye Works, Hackney Wick, E., Dyer.
1898. Cook, Thos. Alex., East London Soap Works, Bow, E., Soapmaker.
1916. Cooke, Frank, Trafford House, Marley Hill, Swallow, S.O., Co. Durham, Chemist.
1916. Cooke, Norman, 23, Woodville Grove, South Reddish, Stockport, Research Chemist.
1904. Cooke, W. Tennent, The University, Adelaide, South Australia, Lecturer in Chemistry.
1910. Coombs, Frank A., Technical College, Sydney, N.S.W., Australia, Lecturer on Tanning.
1910. Cooper, Leonard H., Royal Crown Soap Co., Calgary, Alberta, Canada, Chemist.
1901. Cooper, T. S., Beekfoot, Birch Hall Lane, Manchester, Calico Printing Chemist.
1891. Cooper, Walter J., The Elms, Laverdock, nr. Penarth, South Wales, Cement Works Manager.
1916. Cooper, W. F., Cooper Laboratory for Economic Research, Rickmanworth Road, Watford, Herts, Synthetic Chemist.
1917. Cooper, William R., 113, Tulse Hill, London, S.W., Consulting Engineer.
1914. Corder, Walter S., Messrs. Williamson and Corder, Ltd., Low Walker, Newcastle-on-Tyne, Chemical Manufacturer.
1916. Coriolis, E. G. de, 137, McGill Street, Montreal, Canada, Consulting Chemist.
1916. Corker, Jas. S., c/o Chas. Macintosh & Co., Ltd., Cambridge Street, Manchester, Rubber Works Chemist.
1899. Cornelison, Dr. Robt. W., 275, West Summit Street, Somerville, N.J., U.S.A., Consulting Chemist.
1909. Cornell, Fred, 16, Place Royal, Montreal, Canada, Chemical Merchant.
1894. Coste, J. H., Utopia, Gloucester Road, Teddington, Chemist.
1913. Cotterill, John W., 5, King Alfred's Place, Birmingham, Analyst.
1917. Cottrell, Alin. A., Staff Quarters, Eastriggs, Annan, N.B., Acids Section Manager.
1916. Couch, Daniel L., 88, Rue de Chezy, Neuilly/Seine, near Paris, France, Technical and Analytical Chemist.
1915. Coulton, C. P., Room 114 I, Trench Warfare Supply Dept. (Ministry of Munitions of War), King Charles Street, Whitehall, S.W., Chemist.
1912. Coupe, Geoffrey, "Hainault," Havering Road, Romford, Essex, Chemist.
1917. Course, Herbert E., c/o Secondee Water Works, Secondee, Gold Coast, Chemist.
1894. Cousins, W. J., Cromwell House, High Holborn, W.C., Consulting Chemist and Director.
1909. Coventry, Bernard O., Lahore, Punjab, India, Deputy Commissioner of Forests.
1903. Cowan, A. Wallace, 58, Garscube Terrace, Murrayfield, Edinburgh, Analytical Chemist.
1906. Cowan, George D., Meynell House, Rowlands Gill, Co. Durham, Manager, Desilverising Works.
1912. Cowan, H. W., 22, Cornish Road, Moore Park, Toronto, Canada, Water and Sewage Specialist.
1893. Cowan, W. J., 12, Park Avenue, Wood Green, N., Fine Colour Manufacturer.
1910. Coward, Dr. Hubert F., Dept. of Scientific and Industrial Research, 15, Great George Street, Westminster, London, S.W., Lecturer in Chemistry.
1897. Cowburn, Arthur W., 20, Mount Street, Manchester, Chemical Merchant and Analytical Chemist.
1907. Cowburn, J. Robert, 10, Eastwood Road, South Woodford, Essex, Technical Chemist.
1916. Cowdery, Walter, Price's Patent Candle Co., Ltd., 36, Elspeth Road, Clapham Common, London, S.W., Chemist.
1891. Cowper-Coles, Sherard Osborn, 1 and 2, Old Pye Street, S.W., and (Inds.) The Cottage, French Street, Sunbury-on-Thames, Metallurgical Engineer.
1905. Cox, Harold N., c/o Lalanc and Grosjean Mfg. Co. Woodhaven, N.Y., U.S.A., Chemist.
1917. Cox, Samuel J., 4, Cross Road, New Southgate, N., Works Chemist.
1915. Coye, Chas. H., c/o C. H. Dexter and Sons (Inc.), Windsor Locks, Conn., U.S.A., Paper-Maker.
1915. Craggs, J. W., 1, Gladstone Terrace, Whitley Bay, Northumberland, Analytical Chemist.
1884. Craig, Geo., Chemical Laboratory, 95, Bath Street, Glasgow, Technical Chemist.
1916. Craig, Robert, "Benmore," Bromborough, Cheshire, Technical Manager (Lever Bros.).
1895. Craig, Dr. Thos. J. L., 97, Clyde Street, West Didsbury, Manchester, Chemist.
1908. Craig, Wm. J., Casa Colon, Huelva, Spain, Analytical Chemist.
1901. Crane, Fred. D., 28, Hillside Avenue, Montclair, N.J., U.S.A., Consulting Chemist.
1902. Crane, Jasper E., Chemical Dept., E.I. du Pont de Nemours & Co., Wilmington, Del., U.S.A., Chemist.
1903. Cranmer, Ridgeway, 170, 88th Street, Bay Ridge, Brooklyn, N.Y., U.S.A., Chemist.
1902. Craven, Alfred B., "Northcote," Thorpe Road, Selby, Yorks., Analytical Chemist.
1906. Craven, J. A., 119, Moorside, Armley, Leeds, Chemist.
1906. Craven, John L., Norumbega, Hebers Ghyll, Ilkley, Yorks, Chemist and Salesman.
- O.M. Crawford, D., 60, Holly Avenue, Jesmond, Newcastle-on-Tyne, Manager.
1913. Crawford, John, 76, Forsyth Street, Greenock, Scotland, Works Chemist.
1908. Crawford, Lawrence, Littleburn Tar Works, Durham, Analytical Chemist.
1890. Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.
1914. Creese, Guy T., 2, Poplar Street, Danvers, Mass., U.S.A., Leather Manufacturer.
- O.M. Cresswell, C. G., Ermyngarth, Ashted, Surrey, Chemist.
1916. Cresswick, John A., I.M. Factory, Langwith, near Mansfield, Analyst and Inspector.
1901. Cribb, Cecil H., 60, Greek Street, Soho Square, London, W., Analytical and Consulting Chemist.
1908. Crighton, Adam M., "London Place," Agecroft Print Works, Pendleton, Manchester, Calico Printer's Chemist.
1910. Crighton, David T., 1315, Queen Insurance Buildings, 10, Dale Street, Liverpool, Buying Manager.
1905. Crighton, W. H., The Brough Lead Works, Bradwell, via Sheffield, Chemist.
1890. Cripser, Wm. R., c/o Messrs. D. Waldie and Co., Konnagar, near Calcutta, India, Manufacturing Chemist.

1911. Croasdel, Jas. F., 2, Moorland Terrace, Leeds, Engineer.
1901. Cronquist, G. W., S. Trädgårdsgatan 2, Helsingborg, Sweden, Consulting Ceramic Engineer.
1915. Cronshaw, Cecil J. T., c/o Levinstein, Ltd., Ellesmere Port, near Chester, Research Chemist.
- O.M. Crookes, Sir Wm., O.M., F.R.S., 7, Kensington Park Gardens, Notting Hill, W., Analytical Chemist.
1896. Crosby, Thos., Llanelly Steelworks, Llanelly, South Wales, Metallurgist.
- O.M. Crosfield, A. L., 46, Bidston Road, Oxtou, Birkenhead; (Journals) c/o Prof. B. Moore, Biochemical Dept., The University, Liverpool, Analytical Chemist and Assayer.
1896. Crosfield, Capt. G. R., Lodge Lane, Warrington Soap Manufacturer.
1917. Crosland, Charles K., c/o L. B. Holliday and Co., Huddersfield, Chemical Manufacturer.
1908. Crosland, Percy F., Century Dye Works, Elland, Yorks, Technical Chemist.
1884. Cross, C. F., F.R.S., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.
1917. Cross, Samuel M., Levinstein Ltd., Blackley, Manchester, Research Chemist.
1917. Cross, Lt.-Col. Sir Wm. C., Bart., 44, Queen's Gate Gardens, London, S.W., Chemical Manufacturer.
1894. Crossley, Prof. Arthur W., F.R.S., King's College, Strand, and (Jnks.) 46, Lindfield Gardens, Hampstead, N.W., Professor of Chemistry.
1915. Crossley, Henry, 105, Edenfield Road, Rochdale, Engine Packing Maker.
1904. Crossley, T. Linsey, c/o J. T. Donald & Co., 43, Scott Street, Toronto, Canada, Technical Chemist.
1908. Croston, Henry, Marcus Hook, Pa., U.S.A., Foreman.
1894. Crow, Henry W., Hart's Lane, North Street, Barking, E., Tar Distiller.
1915. Crowley, Thomas, 13, Cliff on Road, Devizes Road, Salisbury, Gas Engineer and Chemist.
1883. Crowther, Horace W., The Beeches, West Bromwich, Technical Chemist.
1906. Crowther, R. E., Westwood, Langford Road, Heaton Chapel, near Stockport, Chemist.
1912. Cruikshanks, Dr. Geo. S., Royal Technical College, Glasgow, Chemist.
1916. Cruse, Henry, 6, Crumpsall Green, Manchester, Engineer.
1906. Cruser, Dr. Fred. Van D., c/o The Diamond Match Co., Oswego, N.Y., U.S.A., Chemical Engineer.
1892. Cullen, Wm., c/o British South African Explosives Co., Ltd., 612, Salisbury House, Finsbury Circus, London, E.C., Chemist.
1903. Cullen, W. H., The Castner-Kellner Alkali Co., Ltd., Wallsend-on-Tyne, Engineer.
1897. Culmann, Dr. J., c/o G. Siegle Co., Rosebank, Staten Is., N.Y., U.S.A., Chemist and Colourist.
1883. Cumming, James, jun., Chemical Works, Yarraville, Melbourne, Vic., Australia, Chemical and Fertiliser Manufacturer.
1912. Cumming, Wm. F., c/o Cumming, Smith, and Co. Proprietary, Ltd., Yarraville, Victoria, Australia, Manufacturing Chemist.
1916. Cumming, Dr. A. C., 2, Relugas Road, Edinburgh, Chemist.
1916. Cumming, Wm. M., 26, Osborne Road, Birkby, Huddersfield, Works Chemist (British Dyes, Ltd.).
1907. Cunningham, James E., Minas Peña del Hierro, Provincia de Huelva, Spain, Analytical Chemist.
1915. Cunningham, Thos. R., 33, Mentz Apartment, Niagara Falls, N.Y., U.S.A., Chemist.
- O.M. Curphey, W. S., 87, Canfield Gardens, South Hampstead, N.W., Chief Alkali Works Inspector.
1916. Curran, E. A., 27, St. Jean Baptiste Street, Montreal, Canada, Manufacturing Chemist.
1916. Currier, Richard J., P.O. Box 178, Fulton, N.Y., U.S.A., Chemist and Colourist.
1898. Curtis, Marvin, 108, Front Street, San Francisco, Cal., U.S.A., Wine Chemist.
1903. Cushing, Robt. P., c/o Cattaraugus Tanning Co., Olean, N.Y., U.S.A., Chemist.

1902. Cutbush, Chas. G., 59, Byne Road, Sydenham, Kent, Electrical Engineer.
1899. Cutler, Fred. F., 166, Essex Street, Boston, Mass., U.S.A., Publisher.
1913. Cutts, H. Cyril, Brooklyn, Private Road, Sherwood, Nottingham, Embroidery Manufacturer.
1904. Cutts, Henry E., Grand View Terrace, Tenally, New Jersey, U.S.A., Technical Chemist.

D

1911. Dager, Herman J., 278, Jarvis Street, Toronto Canada, Dominion Food Inspector.
1897. Dajns, Herbert H., c/o J. E. Ferguson, 2, Union Court, London, E.C., Analytical Chemist.
1915. Daley, Samuel F., H. Fitzwarren Street, Seedley, Manchester, Works Chemist.
1884. Daniell, Louis C., Royal Standard Brewery, Tamworth, New South Wales, Brewer.
1904. Danker, Dan. J., 73, Dean Road, Brookline, Mass., U.S.A., Dyestuff and Chemical Merchant.
1903. Dannenbaum, Dr. H., c/o National Ammonia Co., Frankford, Philadelphia, Pa., U.S.A., Secretary and Treasurer.
1885. Darby, Jno. H., Howard Chambers, 155, Norfolk Street, Sheffield, Ironmaster.
1916. Dargie, Andrew, 140, Perth Road, Dundee, City Analyst.
1916. Darzens, Prof. Georges A., 22, Avenue Ledru-Rollin, Paris, France, Professor of Chemistry.
1916. Das, Dr. Durga C., Barabazar, P.O. Midnapore, Bengal, India, Medical Practitioner.
1916. Dayer, B. F., 32, Churchgate Street, Fort, Bombay, India, Chemical Engineer.
1917. Davey, David R., 38, Harvey Road, Hornsey, London, N., Analytical and Research Chemist.
1911. David, Edward J., 249, Wood Avenue, Tottenville, Staten Is., N.Y., U.S.A., Chemist and Assayer.
1900. Davidson, Alex., St. Helen's, Biggar, Analytical Chemist.
1917. Davidson, Alfred N., 17, Highbury, Newcastle-on-Tyne, Commercial Manager.
1899. Davidson, Charles, 24, Hamilton Drive, Cambuslang, Glasgow, Analytical Chemist.
1901. Davidson, G. M., Chicago and N.W. Railroad Shops, P.O. Station E., Chicago, Ill., U.S.A., Chemist.
1883. Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.
1891. Davidson, Richard, 272, Strathmartine Road, Dundee.
- O.M. Davidson, R. Holden, c/o United Alkali Co., Ltd., Ammonia Soda Works, Fleetwood, Works Manager.
1911. Davidson, Thos. A., 53, Galpins Road, Thornton Heath, Surrey, Chemist and Varnish Expert.
1905. Davidson, Dr. Wm. B., c/o British Dyes Ltd., Huddersfield, Chemical Engineer.
1906. Davies, Harry R., 80, Prince Street, Jamaica Plain, Mass., U.S.A., Chemist.
1898. Davies, Herbert E., The Laboratory, 28, Chapel Street, Liverpool, Analytical Chemist.
1907. Davies, James, 12, Harefield Road, Brockley, London, S.E., Scientific Apparatus Maker.
1911. Davies, Jas. H., c/o Lever Bros., Ltd., Royal Liver Building, Liverpool, Chemist.
1896. Davies, Llewellyn J., 103, Bute Road, Cardiff, Analytical and Consulting Chemist.
1886. Davies, M. L., Standard Chemical Iron and Lumber Co., Toronto, Canada, General Manager.
1897. Davies, Saml. H., c/o Rowntree and Co., Ltd., The Cocoa Works, York, Research Chemist.
1908. Davies, T. H., c/o John Cox and Co.'s Successors, Stillhouse Lane, Bedminster, Bristol, Tanner.
- O.M. Davis, A. R., 12, Heaton Moor Road, Stockport, Analytical Chemist.
1901. Davis, Bernard F., 35, Aldermay Road, Bromley, Kent, Metallurgical Engineer.
1902. Davis, Charles B., c/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A., Technical Chemist.

1912. Davis, E. Gordon, "Holmbury," Streatham Road, Mitcham, Research Chemist.
1914. Davis, Eric, N., 68, Bowrons Avenue, Wembley, N.W., Technical Journalist. On Active Service; retain Journals.
1908. Davis, G. Keville, 265, Strand, London, W.C., Chemical Engineer.
1897. Davis, Wm. A., Agricultural Research Institute, Pusa, Bihar, India, Chemist.
1911. Davis, Wm. C., c/o The British Cyanide Co., Ltd., Popes Lane, Oldbury, Worcestershire, Chemist.
1900. Daw, Fred W., Duffryn House, Ebbw Vale, Mon., Metallurgical Chemist.
1916. Dawe, Alfred E., H.M. Stationery Office, London, S.W., Assistant Examiner of Paper.
- O.M. Dawson, C. A., 32, Elm Hall Drive, Mossley Hill, Liverpool, Technical Chemist.
1917. Dawson, George, Kings Mill Dycworks, Huddersfield, Wool and Cotton Dyer.
1916. Dawson, J. A. M., Inland Revenue Laboratory, 249, Hastings Street East, Vancouver, B.C., Canada, Analyst-in-Charge.
1915. Dawson, Reginald D., Chemical Dept., Southern Outfall Works, Crossness, Abbey Wood, Kent, Chemist.
1886. Dawson, W. Haywood, British Alizarin Co., Ltd., Silvertown, E., and (Journals) 15, Wrotesley Road, Woolwich S.E. Technical Chemist.
1901. Day, Dr. David T., 715, 19th Street N.W., Washington, D.C., U.S.A., Geologist.
1913. Day, Frank E., c/o Condensed Milk Co. of Ireland, Lansdowne, Limerick, Ireland, Analytical Chemist.
1912. Day, G. A. C., Casilla No. 417, Lima, Peru (*via* New York), Oil Mill Manager.
- O.M. Deacon, H. Wade, 8, Ullet Road, Liverpool; and (Jnls.) c/o C. E. Tyers, 186, Derby Road, Farnworth, Widnes, Alkali Manufacturer.
1911. Dean, Arthur L., College of Hawaii, Honolulu, H.I., U.S.A., Assistant Prof. of Industrial Chemistry.
1892. Deaville, B., Beech Avenue, Nottingham, Manufacturing Chemist.
1899. De Castro, J. Paul. *See* Castro, J. Paul de.
1902. De Cew, J. A., 903, McGill Building, Montreal, Canada, Chemical Engineer.
1900. Deerr, Noel F., 28, Fort Greene Place, Brooklyn, N.Y., U.S.A., Analytical Chemist.
1902. Deghucé, Dr. Jos. A., 39, West 38th Street, New York City, U.S.A., Chemist.
1911. Dehn, Dr. Frank B., Broad Sanctuary Chambers, Westminster, S.W., Chemist and Patent Agent.
1908. Delafield, Dr. F. H., Winnington, Northwich, Cheshire, Chemical Manufacturer.
1916. Delage, Edmond, Usines de Prod. Chim. de la Cie. de St. Gobain, 1, Place des Saussaies, Paris (S), France, Director-General.
1909. De Laire, Edgar, 129, Quai de Moulineaux, Issy, Seine, France, Industrial.
1901. Delany, Chas., c/o Elliott Bros., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Chemist.
1915. De Laporte, A. V., 90, Gloucester Street, Toronto, Canada, Chemist, Provincial Board of Health.
1916. Dellow, John, 11, Hardwick Grove, West Bridgford, Nottingham, Perfumery-Chemist.
1908. Dellschaft, Dr. F. H. *See* Delafield.
1910. De Meets, Etienne, Beacon Falls, Conn., U.S.A., Chemist.
1888. Dempsey, Geo. C., 165, Market Street, Lowell, Mass., U.S.A., Chemist.
1916. Dempster, Tom, 7, Lugard Road, Aigburth, Liverpool, Analytical Chemist.
1909. Demuth, Rudolph, 68, Salisbury Road, London, N.W., Manufacturer.
1899. Denham, Wm. S., Chiswick Laboratory, Church Wharf, The Mall, Chiswick, W.
1913. Denington, R. C., 69, Dover Road, South Wanstead, Essex, Research Chemist.
1891. Denison, Joseph R., Valley Dycworks, Bradford, Yorks, Analytical Chemist.
1911. Dennis, Louis, 2, Norman Avenue, Birkby, Huddersfield, Works Chemist.
1908. Dennis, Martin, 859, Summer Avenue, Newark, N.J. U.S.A., Manufacturing Chemist.
1907. Dennison, Henry S., c/o Dennison Manufacturing Co., Framingham, Mass., U.S.A., Manufacturer.
1898. Dent, Dr. Frankland, Government Analyst's Dept., Singapore, Straits Settlements, Government Analyst.
1917. Dent, James H., Low Elswick House, Newcastle-on-Tyne, Analytical Chemist.
1912. Depierres, Gaston, The Indestructible Paint Co., King's House, King Street, Cheapside, London, E.C., Managing Director.
1911. Derry, Albert Victor, 301, Glossop Road, Sheffield, Gas Engineer.
1913. Desch, Dr. Cecil H., Metallurgical Dept., The University, Glasgow, Lecturer.
1912. Dettmann, A. H., Stuart Street, Longueville, Sydney, N.S.W., Leather Manufacturer.
1914. Detwiler, Jas. G., c/o The Texas Co., Port Arthur, Texas, U.S.A., Chemist.
1916. Devereux, Percy S., Keeling and Walker, Ltd., Stoke-on-Trent, Chemist and Manager.
1898. Dewar, Alex. H., c/o The Linoleum Manufacturing Co., Staines, Middlesex, Chemist.
- O.M. Dewar, Sir J., F.R.S., 21, Albemarle Street, London, W., Professor of Chemistry and Physics.
1889. Dewey, Fred. P., 832, Varnum Street, N.W., Washington, D.C., U.S.A., Metallurgist.
1904. Dewhurst, J. A., Imperial Chambers, Halifax, Yorks, Analyst.
1909. Dewhurst, Wm. B., Gen. Delivery, Carnegie, Pa., U.S.A., Technical and Engineering Chemist.
1915. Dey, Alex. J., Blandfield Chemical Works, Wheatfield Road, Edinburgh, Manufacturing Chemist.
1903. Diamond, Wm., La Norie, Marley Hill, Co. Durham, Works Manager.
1913. Diaz-Ossa, Prof. Belisario, Casilla 962, Santiago, Chile, Prof. of Chemistry.
- O.M. Dibdin, W. J., 31, Idmiston Road, West Norwood, London, S.E., Analytical Chemist.
1916. Dick, Chas. Wm., 8, Vicarage Road, Frindsbury, Rochester, Kent, Chemist.
1913. Dick, James, c/o Canadian Explosives, Ltd., Beloeil Station, P.Q., Canada, Superintendent.
1902. Dick, John, Wharf Road, Cubitt Town, London, E., Manager and Chemist.
1904. Dick, W. D., c/o Hugh Baird and Sons, 29, St. Vincent Place, Glasgow, Analytical Chemist.
1898. Dickenson, F. M., c/o Broken Hill Proprietary Co., 3, Great Winchester Street, London, E.C., Secretary.
1904. Dickenson-Gair, C. J. *See* under Gair.
1893. Dickerson, E. N., 141, Broadway, New York City, U.S.A., Lawyer.
1905. Dickinson, Cyril, Southwark Town Hall, Walworth Road, London, S.E., Analytical Chemist.
1914. Dickson, J. M., 36, Leopold Street, Toronto, Canada, Manager.
1898. Dickson, Samuel, 26, Tothill Street, Westminster, S.W., Analytical Chemist.
1908. Diekman, Dr. George C., 115, West 68th Street, New York City, U.S.A., Professor of Pharmacy.
1908. Dill, Colby, Rahway Avenue, Woodbridge, N.J., U.S.A., Chemist.
1898. Dillon, Wm., 11, Ingledew Crescent, Roundhay, Leeds, Works Chemist.
1916. Dixon, Alfred, 15, Lonsdale Place, Whitehaven, Cumberland, Tanner.
1899. Dixon, Fred. W., P.O. Box 43, Jamestown, N.Y., U.S.A., Dyer.
1888. Dixon, Prof. Harold B., F.R.S., Owens College, Manchester, Professor of Chemistry.
1902. Dixon, Wm. A., Reiby Chambers, Reiby Lane, Circular Quay, Sydney, N.S.W., Australia, Public Analyst and Assayer.
1909. Dixon, W. P., c/o Bryant and May, Ltd., Fairfield Works, Bow, London, E., Match Manufacturer.
1892. Dobb, Thos., c/o J. T. Dobb and Son, West Bar, Sheffield, Pharmaceutical Chemist.
- O.M. Dobbie, Sir J. J., F.R.S., Government Laboratory, Clement's Inn Passage, London, W.C., and (Jnls.) 4, Vicarage Gate, Kensington, W., Director.

1908. Dobbs, Ernest J., Laboratory, 12, Camomile Street, Bishopsgate, E.C., Analytical Chemist.
1907. Dodd, Arthur J., 2, Criffel Avenue, Streatham Hill, S.W., Oil Manufacturer.
1915. Dodd, A. Scott, Laboratory of City Analyst, 20, Safford Street, Edinburgh, Public Analyst.
1917. Dodd, Robert, Birch Vale Cottage, Romiley, Ches., Chemist.
1889. Dodd, W. Ralph, Burton Grange, Goff's Oak, near Cheshunt, Chemical Works Manager.
1913. Dodds, Herbert H., c/o Kynoch, Ltd., Umbogintwini, Natal, Explosives Chemist.
1917. Dodds, James M., c/o Bristol Box and Printing Co., Ltd., Greenway Bush Lane, Bristol, Works Manager.
1906. Dodds, Thos., c/o Reckitt and Sons, Ltd., and (Journals) 7, The Oval, Garden Village, Hull, Works Manager and Chemist.
1900. Dodge, Dr. Francis D., 69, Avenue A., Bayonne, N.J., U.S.A., Chemist.
1897. Doerflinger, Wm. F., Rosebank, Staten Island, N.Y., U.S.A., Research Chemist.
1897. Dohme, Dr. Alf. R. L., Messrs. Sharp and Dohme, Baltimore, Md., U.S.A., Manufacturing Chemist.
1905. Dolan, H., Westbourne, Belvoir Road, Lower Walton, Warrington, Chemist.
1914. Donald, James R., c/o Imperial Ministry of Munitions, Transportation Building, Ottawa, Canada, Chemical Engineer.
1903. Donald, Dr. Jas. T., 318, Lagachetière Street West, Montreal, Canada, Consulting Chemist.
1900. Donald, Wm. Bridgefield Park, Bergen Co., N.J., U.S.A., Assayer and Chemist.
1917. Donald, William E., Vista Alegre 3, Minas de Rio Tinto, S. Spain, Chemical Engineer. Retain Journals.
1913. Donaldson, Richard, 63, Waverley Gardens, Crossmyloof, Glasgow, Assistant Manager.
1902. Donaldson, Thos., Beecheroff, Ardrossan Road, Saltcoats, Scotland, Analytical Chemist.
1905. Donnan, Prof. F. G., F.R.S., Chemical Laboratories, University College, Gower Street, London, W.C., Professor of Physical Chemistry.
1886. Doolittle, Orrin S., 388, Palisade Avenue, Yonkers, N.Y., U.S.A., Chemist.
1905. Doolittle, Roscoe E., 109, Hillside Avenue, Glen Ridge, N.J., U.S.A., Chemist.
1890. Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., Distiller's Engineer.
1911. Dorce, Dr. Charles, 56, Albany Mansions, Battersea Park, London, S.W., Head of Chemistry Department, Borough Polytechnic.
1896. Doremus, Dr. Clas. A., 55, West 53rd Street, New York City, U.S.A., Professor of Chemistry.
- O.M. Dott, D. B., Ravenslea, Musselburgh, Scotland, Analytical Chemist.
1917. Dougal, John W., 38, Royal Park Terrace, Edinburgh, Chemist.
1911. Dougall, Jas. S. N., 305, Manufacturers' Street, Montreal, Canada, Varnish Manufacturer.
1915. Dougall, George, Royd House, Watkney Lane, Heckmondwike, Yorks, Gas Engineer.
1897. Douglas, Geo., Farfield Hall, Addingham, Yorks, Dyer.
1915. Douglas, John, Reed Street, Cliff-at-Ilco, Kent, Explosives Chemist.
1894. Douglas, Loudon M., Douglas Wharf, Putney, S.W., Chemical Manufacturer.
1909. Douglas, Robt. P., Prudential Buildings, Nelson Square, Bolton, Consulting Chemist.
1884. Douglas, William, Gratton House, Berkhamsted, Herts., Chemical Engineer.
1900. Doulton, H. Lewis, Royal Doulton Potteries, Lambeth, S.E., Potter.
1900. Dow, Allan W., 131 E. 23rd Street, New York, U.S.A., Chemical Engineer.
1898. Dow, Herbert H., c/o The Dow Chemical Co., Midland, Mich., U.S.A., Manufacturing Chemist.
1908. Dow, John W., 564, Park Avenue West, Mansfield, Ohio, U.S.A., Manufacturing Chemist.
1905. Dowbiggin, James, Craiglands, Albert Park, Lancaster, Chemist.
1915. Downing, James, jr., 17, Hallswelle Road, Golder's Green, London, N.W.
1912. Doxey, Carl W., c/o Dinting Vale Printworks, Dinting, near Manchester, Printworks Chemist.
1901. Doxrød, Christian, Technical School, Christiania, Norway, Professor of Chemical Technology.
1907. Doyle, B. W., 245, Lindell Avenue, Leominster, Mass., U.S.A., Manufacturer.
1902. Drake, Bryant S., 5830, Colby Street, Oakland, Cal., U.S.A., Chemist.
1911. Drake, Joseph W. D., Three Mills Distillery, Bromley-by-Bow, London, E., Distillery Brewer.
1914. Drew, John M., Lower House, Burnley, Lancashire, Calico Printer.
1906. Drew, W. Newton, Raincliffe, Ecclesfield, near Sheffield, Chemical Manufacturer.
1896. Drewsen, Dr. Viggo B., 5, Beckman Street, New York City, U.S.A., Wood Pulp and Paper Expert.
- O.M. Dreyfus, Dr. C., Claremont, Fallowfield, Manchester. Retired Dye Manufacturer.
1904. Dreyfus, Dr. L. A., Maple Avenue, Rosebank, S.I., N.Y., U.S.A., Chemist.
1893. Dreyfus, S., Thorncliffe Villa, Windmill Lane, Denton, near Manchester, Chemist.
1899. Dreyfus, Dr. Wm., 57, East 96th Street, New York City, U.S.A., Chemist.
1917. Drummond Alan A. I., Fairhaven Mansions, Lower Hill, S.E., Research Chemist.
1898. Drummond, Dr. Isaac W., 436, West 22nd Street, New York City, U.S.A., Chemist.
1910. Drury, Chas. Dru, Hendon Gas Works, Sunderland, Gas Engineer.
1899. Ducas, B. P., 25-27, South William Street, New York City, U.S.A., Chemical and Dyestuff Importer.
1909. Duchemin, René P., 6, Rno Chanoinesse, Paris IV., France, Chemical Engineer.
1897. Duckham, Alex., Phoenix Wharf, West Ferry Road, Millwall, E., and (Journals) 130, St. James's Court, Buckingham Gate, S.W., Chemical Manufacturer.
1915. Duckham, Sir Arthur M., K.C.B., Palace Chambers, Westminster, S.W., Engineer.
1917. Duckworth, Charles W., 747, Ashton New Road, Clayton, Manchester, Director and Secretary.
1905. Duckworth, Harry S., Garner Printworks, Garnerville, Rockland Co., N.Y., U.S.A., Printworks Superintendent.
1913. Duff, Alex. R., 211, Fern Avenue, Toronto, Canada, Rubber Chemist.
1899. Duff, Wm. S., Merrie Lands, Westbury Road, Buckhurst Hill, Essex, Manufacturing Chemist.
1901. Dufy, Lawrence, 92, Tom Lane, Nether Green, Sheffield, Analytical Chemist.
1905. Duggan, Edw. J., c/o Brewer and Co., 95, William Street, New York City, U.S.A., Vice-President.
- O.M. Duggan, T. R., 52, East 41st Street, New York City, U.S.A., Analytical Chemist.
1916. Duke, J. A. H., The Dell, Sutton, Surrey, Edible Oil Manufacturer.
1888. Dukes, T. William, Box 10, Vrijheid, South Africa, Merchant.
1906. Duncalfe, Roger, Forge Mills, Bestwood Colliery, Nottingham, Glue Manufacturer.
1889. Duncan, Arthur W., c/o J. Woolley, Sons and Co., Ltd., Victoria Bridge, Manchester, Analytical Chemist.
1916. Duncan, James B., 50, Hotspur Street, Tynemouth, Works Manager.
1909. Duncan, Jas., c/o Steel Bros. and Co., Ltd., 6, Fenchurch Avenue, London, E.C., Merchant.
1915. Duncan, J. Gibson, 67, Waverley Gardens, Crossmyloof, Glasgow, Works Chemist.
1906. Dunford, Jno. H., Trent Side Bone Works, Nottingham, Managing Director.
1915. Dunglison, B., c/o Messrs. Blair, Campbell and McLean, Woodville Street, Govan, Glasgow, Chemical Engineer.

1912. Dunkelsbühler, F. S., 63, Brook Street, Grosvenor Square, London, W., Technical Chemist.
1905. Dunnlop, Harry, 231, St. Vincent Street, Glasgow, Chemist.
- O.M. Dunn, Dr. J. T., 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.
1915. Dunningham, Dr. Alfred C., c/o Electro-Bleach and By-Products Ltd., Middlewich, Cheshire, Technical Chemist.
1901. Dunsford, Geo., Laboratory, Wigan Coal and Iron Co., Ltd., Wigan, Analytical Chemist.
1907. Dunstan, Dr. A. E., "Meadhurst," Feltham Hill, Sunbury-on-Thames. Head of Chemical Department (Technical College), East Ham.
1907. Dupré, F. H., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.
1907. Dupré, P. V., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.
1916. Durden, Frank, 288, Liverpool Road, Cadishead, near Manchester, Chemist.
1905. Durfee, Winthrop C., 516, Atlantic Avenue, Boston, Mass., U.S.A., Manufacturing Chemist.
1897. Durkee, Frank W., Tuft's College, Medford, Mass., U.S.A., Professor of Chemistry.
1911. Durkin, Jos. A., British Chemical Co., Ltd., Trenton, Ont., Canada, Chemical Superintendent.
1907. Durrans, Thos. H. (Journals to c/o Professor W. H. Perkin, F.R.S., Chemical Laboratories, South Park Road, Oxford), Chemist.
1915. Dutt, P. K., The University, Leeds, Research Chemist.
1891. Dvorkovitz, Dr. F., 4, Broad Street Place, London, E.C., Technical Chemist.
1912. Dyche-Teague, F. C., 258, Gloucester Terrace, Hyde Park, London, W., Analytical Chemist and Bacteriologist.
1916. Dyer, Alfred (Journals to 7, Grisedale Avenue, Birkby, Huddersfield), Analytical and Consulting Chemist. On Active Service (Inns of Court O.T.C.).
- O.M. Dyer, Dr. B., 17, Great Tower Street, London, E.C., Analytical and Consulting Chemist.
1911. Dyke, F. Montague, Nelson Croft, Church Road, Behington, Cheshire, Analytical Chemist.
- O.M. Dyson, C. E., Flint, North Wales.
1902. Dyson, George W., 24, Clarkehouse Road, Sheffield, Analyst.
1892. Dyson, Septimus, Nyddcombe, Warlingham, Surrey, Manufacturing Chemist.
1906. Eaton, B. J., Agricultural Dept., Kuala Lumpur, Selangor, Fed. Malay States, Govt. Chemist.
1909. Eberlin, Leon W., 360, Lake View Park, Rochester, N.Y., U.S.A., Chemist.
1892. Eddy, Harrison P., 14, Beacon Street, Boston, Mass., U.S.A., Superintendent.
1913. Edge, Alfred, Ravenhurst, Clayton Bridge, Manchester, Technical Chemist.
1909. Edge, J. Harold, c/o Wm. Edge and Sons, "Dolly" Blue Works, Bolton, Lancashire, Technical Chemist.
1902. Edison, Thos. Alva, Edison Laboratory, Orange, N.J., U.S.A., Inventor and Manufacturer.
1917. Edmondson, John S., Blaydon Manure and Alkali Co., Ltd., Blaydon-on-Tyne, Works Chemist.
1916. Edon-Brown, Herbert, c/o Nitrogen Products and Carbide Company, Ltd., Dagenham Dock, Essex, Chemical Engineer.
1911. Edwards, Alfred, The Laboratory, Meadow Lane Gas Works, Leeds, Analytical Chemist.
1916. Edwards, Cyril, 6, Sojbie Road, Nottingham, Research Chemist.
1909. Edwards, George M., 241, Pine Avenue West, Montreal, Canada, Paintworks Manager.
1915. Edwards, H. C., "Neotsbury," Laton Road, Hastings, Chemist.
1902. Edwards, H. Leaton, The Shanty, Banks Avenue, Meols, Hoylake, Cheshire, Analyst.
1915. Edwards Owen C., 46, Saxon Road, Faversham, Kent, Works Chemist.
1917. Edwards, William, Ericka, Park Road, Dartford, Kent, Factory Manager.
1895. Ehrenfeld, Prof. Chas. H., York Collegiate Institute, York, Pa., U.S.A., Professor of Chemistry.
1896. Ehrhardt, Ernest F., The Mersey Chemical Works, Bromborough Port, New Ferry, Cheshire, Research Chemist.
1913. Eipper, William R., Meadow Brook, Dallas, Pa., U.S.A., Chemist.
1909. Eisenhart, M. H., c/o Eastman Kodak Co., Kodak Park, Rochester, N.Y., U.S.A., Chemist.
1916. Eldridge, A. A., 63, Ellerton Road, Surbiton, Chemist.
1916. Eldridge, Gardner S., 567, Hornby Street, Vancouver, B.C., Canada, Analytical Chemist.
1901. Elkan, Leo H., Tannery, 1511, Webster Avenue, Chicago, Ill., U.S.A., Tanner.
1901. Elkins, Arthur W., 116, Prospect Street, East Orange, N.J., U.S.A., Civil Engineer.
1917. Ellingworth, Samuel, 74, Millfield Road, York, Chemist.
1884. Elliott, Dr. A. H., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Consulting Chemical Engineer.
1912. Elliott, Edward, c/o Reckitts (Over-Sea), Ltd., Burke Street, Redfern, N.S.W., Australia, Chemical Engineer.
1907. Elliott, George K., c/o Lunkenheimer Co., Cincinnati, Ohio, U.S.A., Chief Chemist.
1896. Elliott, Dr. J. F., O'Connell Street, Sydney, N.S.W., Manufacturing Chemist.
1902. Elliott, Victor G., Chemical Works, Rozelle, Sydney, N.S.W., Australia, Manufacturing Chemist.
1905. Ellis, Carleton, 143, Gates Avenue, Montclair, N.J., U.S.A., Chemical Engineer.
1893. Ellis, E. Victor, c/o McLellan, 31, Gayfield Square, Edinburgh, Analytical Chemist.
1894. Ellis, G. Beloe, 70, Chancery Lane, London, W.C., Patent Agent.
1913. Ellis, Henry D., 30, Blackheath Park, S.E., Metallurgical Engineer.
1912. Ellis, Percival W., 90, Tooley Street, London Bridge, S.E., Tanning Material Merchant.
1910. Ellis, Ridsdale, 1626, Lytton Building, Chicago, Ill., U.S.A., Patent Agent.
1910. Ellis, Rowland H., c/o Olympia Oil and Cake Co., Barlby Road, Selby, Yorks, Analytical Chemist.
1891. Ellison, Henry, Moor Lane House, Conersal, near Leeds, Manufacturing Chemist.

E

- O.M. Elmore, A. S., 72, Gloucester Terrace, Hyde Park, London, W., Electro-Metallurgist.
1915. Elphick, Fred. C., c/o Burt, Boulton and Haywood, Ltd., Prince Regent's Wharf, Silvertown, E., Technical Chemist.
1907. Elsdon, A. Vincent, 10, Gourock Road, Eltham, Kent, Analytical Chemist.
1911. Elsdon, Geo. D., Municipal Chemical Laboratory, 141, Regent Road, Salford, Manchester, Public Analyst.
1916. Elsey, Edwin, c/o London Chemical Works, Rubastie Road, Southall, Middlesex, Chemist.
1904. Elson, J. Hugh, Monroe Drug Co., Quincy, Ill., U.S.A., General Manager.
1909. Ely, Benjamin, The Limes, Pye Bridge, near Alfreton, Tar Distiller.
1910. Emanuel, Louis V., c/o River Smelting and Refining Co., Florence, Colorado, U.S.A., Metallurgical Engineer.
1910. Embley, Dr. E. H., 245, Latrobe Street, Melbourne, Victoria, Australia.
1917. Emerson, Frank W., 179, Burton Road, West Didsbury, Manchester, Research Chemist.
1902. Emery, Arthur L., c/o Smith, Emery, and Co., 651, Howard Street, San Francisco, Cal., U.S.A., Chemical Engineer.
1907. Emmons, Frank W., c/o Washburn Crosby Co., Minneapolis, Minn., U.S.A., Chemist.
1894. Enequist, John, 1111, Dean Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1904. Englehard, Charles, 30, Church Street, New York City, U.S.A., Platinum Importer.
1895. English, Frank H., 89, Belgrave Road, Wanstead, N.E., Analytical Chemist.
1917. Enna, Pini G. A., 10a, Springfield Mount, Leeds, Student.
1911. Epps, James W., Holland Street, London, S.E., Chemist.
1902. Erhart, Wm. H., 81, Maiden Lane, New York City, U.S.A., Manufacturing Chemist.
1904. Ermen, Walter F. A., Swiss Cottage, Alderley Edge, Cheshire, Analytical Chemist.
1905. Ernst, Chas. A., The Viscose Co., Marcus Hook, Pa., U.S.A., Chemist.
1897. Escher, Paul, c/o Swift and Co., Chemical Laboratory, Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1884. Esilman, A., 38, Norwood Avenue, Southport, Lancashire, Analytical Chemist.
1913. Esling, Fred., 36, Kenilworth Court, Putney, S.W., Chemical Engineer.
1912. Espenhahn, E. V., c/o Metropolitan Gas Co., 186, Flinders Street, Melbourne, Victoria, Australia, Works Chemist.
- O.M. Estcourt, C., 5, Seymour Grove, Old Trafford, Manchester, Consulting Chemist.
1917. Evans, Edgar C., Rhondra Research Laboratories, Ilwacopia, Glam., Analytical Chemist.
1912. Evans, Edward V., South Metropolitan Gas Co., Old Kent Road, London, S.E., Chief Chemist.
1903. Evans, F. Sparke, Avonside Tannery, Bristol, Tanner.
1905. Evans, John, 67, Surrey Street, Sheffield, Analytical Chemist.
1908. Evans, Prof. Nevil Norton, Redpath Library, McGill University, Montreal, Canada, Associate Professor of Chemistry.
1912. Evans Sam., c/o British Electrolytic Zinc Co. (Islerwood Process, Ltd.), West Bank Works, Widnes, Lancs.
1912. Evans, Ulrik R., 28, Victoria Street, Westminster, S.W., Consulting Electrochemist.
1916. Evans, 2nd Lieut. L. W. (Journals to 115, Machine Gun Company, B.E.F., France), Research Chemist.
1917. Evans, William, 35, Mitchell Street, Ancoats, Manchester, Chemist.
1898. Evans, Wm. Perceval, Canterbury College, Christchurch, New Zealand, Professor of Chemistry.
1916. Everes, Dr. A. E., Dep. of Coal Tar Colour Chemistry, Technical College, Huddersfield, Head of Department.
1909. Everette, Dr. W. E., 3512, South 11th Street, Tacoma, Wash., U.S.A., Consulting Chemical Engineer.
1904. Everitt, Walter, Norwood Wharf, Southall, Middlesex, Analyst.
1912. Evers, Norman, c/o Allen and Hanbury's, Ltd., Bethnal Green, London, E., Analytical Chemist.
1907. Eves, Archie, P., 762, East Buchtel Avenue, Akron, Ohio, U.S.A., Chemist.
1894. Ewan, Dr. Thos., c/o Cassel Cyanide Co., Shuna Street, Maryhill, Glasgow, Chemist.
1905. Eynon, Lewis, 41, Champion Road, Upminster, Essex, Chief Chemist (London Beetroot Sugar Association).
- F
1902. Faill, Jas., 52, Robertson Street, Glasgow, Technical Chemist.
1902. Fairchild, Benj. T., P.O. Box 1120, New York City, U.S.A., Manufacturing Chemist.
1910. Fairclough, Lt.-Col. Brereton, Quarry House, Hill Cliffe, Warrington, Cheshire, Miller.
1911. Fairfield, Thos. J., c/o W. T. Glover and Co., Trafford Park, Manchester, Analytical Chemist.
1903. Fairhall, E. J., Lindfield, Windmill Lane, Southall, Middlesex, Chemist.
- O.M. Fairley, T., 17, East Parade, Leeds, Analytical Chemist.
1901. Fairlie, Jas., Camelon Chemical Works, Falkirk, Manufacturing Chemist.
1917. Falconer, James H., 1848, Venables Street, Vancouver, B.C., Canada, Manufacturer.
1911. Farey, F. O., 905, McGill Building, Montreal, P.Q., Canada, Chemist.
1910. Farr, Harry, Free Library, Cardiff, Librarian.
- O.M. Farrant, N., c/o J. Nicholson and Sons, Ltd., Chemical Works, Hunslet, Leeds, Chemist.
1913. Farrar, Stanley C., 50, Holly Road, Handsworth, Birmingham, Chemical Technologist.
1897. Farrell, Frank James, Shanrahan, Beeches, Suffolk, Artificial Silk Manufacturer. (Journals to c/o Grout & Co., Ltd., Textile Manufacturers, Great Yarmouth.)
- O.M. Farrington, T., 4, Waterloo Place, Cork, Ireland, Chemical Engineer.
1909. Fath, Dr. Arthur, Société Italienne de la Viscose, Vinaria-Reale, Prov. Torino, Italy, Chemical Engineer.
1917. Faust, Thos. A., London, Ontario, Canada, Analytical-Manufacturing Chemist.
1903. Fawsitt, Prof. Chas. E., The University, Sydney, N.S.W., Australia, Prof. of Chemistry.
1914. Fearnley, C. A., 2, Alcester Terrace, Shepherd's Lane, Leeds (Journals to c/o Messrs. Brotherton & Co., Ltd., Holmes Street, Chemical Works, Dewsbury Road, Leeds), Technical Chemist.
1903. Feilmann, Dr. M. E., See Fyleman, Dr. M. E.
1913. Feldenheimer, Wm., 20, Holborn Viaduct, London, E.C. Clay Merchant.
1909. Fell, Wm. M. W., 27, Clarendon Road, Garston, Liverpool, Chemist.
1905. Felton, Herbert L., 516, East Second Street, South Boston, Mass., U.S.A., Distiller.
1900. Ferguson, Prof. Geo. A., 121, West 42nd Street, New York City, U.S.A., Professor of Analytical Chemistry.
1914. Ferguson, Jas., "Mountside," Prestwich Park South, Manchester, Technical Chemist.
1917. Ferguson, John G., Box 195, Stettler, Alta. Canada, Teacher of Chemistry.
1902. Fergusson, Donald M., c/o Acadia Sugar Refining Co., Halifax, N.S., Canada, Analytical Chemist.
1883. Fergusson, H., Prince Regent's Wharf, Silvertown, E., Technical Chemist.
1916. Ferns, John F., 61, Withington Road, Whalley Range, Manchester, Technical Chemist.
1893. Fiebing, John H., 238, Reed Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.

1911. Field, Allan J., c/o G. Siegle Co., Rosebank, Staten Island, N.Y., U.S.A., Analytical Chemist.
1917. Field, Chas. H., 52, Lee Park, Blackheath, S.E., Analytical Chemist.
1885. Field, E. W., Brewer.
1917. Field, Fredk. C., City Hall, Calgary, Alberta, Canada, Analytical Chemist.
1915. Field, G. H., "Holmwood," Dolgarrog, Tal-y-Cafu, N. Wales, Chief Chemist.
1887. Field, S. S., 41, Kidbrook Park Road, Blackheath, S.E., Manufacturing Chemist.
1891. Field, Wm. Eddington, Martin Street, Elsternwick, Melbourne, Victoria, Analytical Chemist.
1907. Finch, Archibald M., Vitriol and Chemical Works, Cattedown, Plymouth, Chemical Manufacturer.
1917. Finch, Wm. J., 9, Stokes Croft, Bristol, Works Manager.
1910. Findlater, James, c/o Price's Patent Candle Co., Ltd., Bromborough Pool, near Birkenhead, Chief Chemist.
1916. Findlater, R. H., c/o Broxburn Oil Co., Ltd., Broxburn, West Lothian, Chemist.
1899. Findland, John J., Kaslo, B.C., Canada, Analytical Chemist.
1911. Fink, F. W., 420, Riverside Drive, New York City, U.S.A., Manufacturing Chemist.
1904. Finn, Cornelius P., Coke Ovens, etc., Departments, Hemsworth Collieries, Fitzwilliam, near Wakefield, Coke Ovens Manager.
1903. Fish, Chas. C. R., 439, Boylston Street, Boston, Mass., U.S.A., Chemist.
1911. Fish, Charles W., c/o The Turner Paper Mill Co., Ltd., Rawcliffe Bridge, S.O., Yorks, Chemist and Paper Technologist.
1917. Fisher, Alfred, 19, Richmond Hill, Langley Green, near Birmingham, Technical Chemist.
1900. Fisher, Henry, 16, East 96th Street, New York City, U.S.A., Teacher of Chemistry.
1916. Fisher, John M., 701, Broadway East, Vancouver, B.C., Canada, Pharmacist.
1915. Fisher, L. E., The Laboratory, Messrs. Ardel, Ltd., Barby Road, Selby, Yorks, Works Chemist.
1917. Fisk, Alan E., 11, Balfour Road, Ilford, London, E., Works Chemist.
1895. Fison, John, Messrs. Jas. Fison and Sons, Thetford, Norfolk, Chemical Manufacturer.
1904. Fitch, A. J., 67, Branstone Road, Burton-on-Trent, Brewer's Chemist.
1916. FitzPatrick, G. D., 33, Church Road, Moseley, Birmingham, Analytical Chemist.
1917. Fleck, Dr. Alexr., c/o Messrs. Castner Kellner Alkali Co., Ltd., Wallsend-on-Tyne, Research Chemist.
1913. Fleming, M. D., c/o S. Fleming & Co., 31, Robertson Street, Glasgow (Journals to Plantation Albion, Berbice, British Guiana), Analyst.
1893. Fletcher, E. Morley, 30, Grosvenor Place, Newcastle-on-Tyne, Alkali Works Inspector.
- O.M. Fletcher, F. W., c/o Fletcher, Fletcher, and Co., Ltd., Holloway, N., Manufacturing Chemist.
1891. Fletcher, R. Jaques, North Geelong, Victoria, Australia, Manufacturing Chemist.
1904. Fletcher, Wm. E., 1104, Rodney Street, Wilmington, Del., U.S.A., Chemist.
1912. Flürscheim, Dr. Bernhard J., Rushmoor, Fleet, Hampshire, Research Chemist.
1899. Focht, Louis, 12, Atterbury Avenue, Trenton, N.J., U.S.A., Civil Engineer.
1890. Foden, Alfred, Fairholme, Mossley Hill Road, Grassendale, Liverpool, Metallurgical Chemist.
1900. Foersterling, Dr. H., c/o Roessler Hasslacher Chem. Co., Perth Amboy, N.J., U.S.A., Chemist.
1916. Foley, Nelson T., c/o Leders and Nucoline, Ltd., Hammersmith, W. (Journals to Lynceot, Monkham's Drive, Woodford, Essex), Assistant Manager and Chemist.
1895. Forbes, Paul R. (Retain Journals), Chemist and Assayer.
1893. Ford, J. B., jun., Michigan Alkali Co., Wyandotte, Mich., U.S.A., Secretary and Treasurer.
1889. Ford, John S., Abbey Brewery, Edinburgh, Analyst.
1914. Ford, Joseph James, c/o Skinner and Holdford, Ltd., Waleswood Collieries, Waleswood, near Sheffield, Analytical Chemist.
1915. Ford, Jos. J., 84, Normandy Avenue, High Barnet, Herts., Agent.
1916. Foreman, Thos. Y., 100, Chamber Street, Newcastle-on-Tyne, Analytical Chemist.
1904. Forrest, Chas. N., Technical Dept., Barber Asphalt Paving Co., Maurer, N.J., U.S.A., Chemist.
1890. Forrester, A. M., c/o Richmond Guano Co., Richmond, Va., U.S.A., Analytical Chemist.
1905. Forrester, H. A., Hill View, Dances Road, Rusholme, Manchester, Chemical Works Manager.
1909. Forshaw, Arthur, c/o John Wright and Co., Ltd., Essex Works, Aston, Birmingham, Works Chemist.
1902. Forstall, Alf. E., 84, William Street, New York City, U.S.A., Consulting Gas Engineer.
1916. Forster, E. L. C., Inland Revenue Laboratory, Postal Station "B," Winnipeg, Canada, Analyst.
1902. Forster, Ferdinand E. P., c/o Messrs. Bass and Co., 19, Guild Street, and (Jnls.) The River House, Burton-on-Trent, Brewer's Chemist.
1907. Forster, Francis, Edgewood, Woodville Road, New Barnet, Lead Manufacturer.
1889. Forster, Joseph F., 17, Hilpot Lane, London, E.C., Chemical Merchant.
1899. Forster, Dr. M. O., F.R.S., Queen Anne's Mansions, St. James's Park, London, S.W., Chemist.
1884. Forster, Sir Ralph C., Bart., c/o Messrs. Beasler, Waechter, and Co., Salisbury House, Finsbury Circus, London, E.C., Chemical Merchant.
1915. Forster, Dr. R. B., c/o Levinstein, Ltd., Blackley, Manchester, Chemist.
1884. Forth, Henry, Stoke Lacy, Marple, Cheshire, Drysalter.
1907. Forward, Charles C., Dept. of Inland Revenue Lab., 50, Bedford Road, Halifax, N.S., Canada, Chemist.
1906. Foster, Robt. K., Church Street, Middle Brighton, Melbourne, Victoria, Pharmaceutical Chemist.
- O.M. Foster, R. Le Neve, Fulshaw Cottage, Wilmslow, Cheshire, Manufacturing Chemist.
1888. Foster, Wm., St. Martin's Terrace, Newton Park, Leeds, Manufacturing Chemist.
1916. Foster, Wm. A. J., South Hall, Farningham, Kent, Paper Manufacturer.
1891. Fowler, Dr. Gilbert J., Indian Institute of Science, Bangalore, India, and (Journals) Frankland Laboratory, Chem. Dept., Victoria University, Manchester, Prof. of Applied Chemistry.
1912. Fox, Charles P., 401, South 3rd Street, Miamisburg, Ohio, U.S.A., Chemist.
1913. Fox, Edward Carey, 27, Scarth Road, Toronto, Canada, Pork Packer.
1917. Fox, Frank, "Varuna," Victoria Road, Grappenhall, Cheshire, Departmental Manager.
1898. Fox, John, 10, Clarendon Road, Eccles, Lancs., Analyst.
1911. Fox, Dr. John J., 6, Alkham Road, Stamford Hill, N.; all communications to c/o Government Lab., 13, Clement's Inn Passage, Strand, W.C., Government Analyst.
- O.M. Fox, T., jun., c/o Fox Bros. and Co., Ltd., Wellington, Somerset, Wool Manufacturer.
1916. Foxwell, G. E., 70, Steade Road, Sharrow, Sheffield, Works Manager and Chemist.
1905. France, Edward W., Philadelphia Textile School, Broad and Pine Streets, Philadelphia, Pa., U.S.A., Director.
1917. Francis, Francis, The University, Bristol, Professor of Chemistry.
- O.M. Francis, G. Bult, The British Drug Houses, Ltd., 22-30, Graham Street, City Road, London, N., Wholesale Druggist.
- O.M. Francis, W. H., 11, Bramham Gardens, South Kensington, London, S.W., Wholesale Druggist.
1894. Frank, Jerome W., 29, Broadway, New York City, U.S.A., Chemist.

1886. Frankenburg, Isidor, Greengate Rubber Works, Salford, Manchester, India-rubber Manufacturer.
1895. Frankforter, Dr. G. B., University of Minnesota, Minneapolis, Minn., U.S.A., Prof. of Chemistry.
- O.M. Frankland, H., Stroonshalh, The Crescent, Louthorpe, Middlesbrough, Analytical Chemist.
- O.M. Frankland, Prof. P. F., F.R.S., The University, Edgbaston, Birmingham, Professor of Chemistry.
1916. Franks, C. F., 10, Woodville Road, Blackheath, S.E., Civil Engineer.
1901. Frasch, Hans A., 52, Broadway, New York City, U.S.A., Manager.
1910. Fraser, Arthur, Casilla 1464, Valparaiso, Chile, Analyst.
1917. Fraser, John, 11, Northumberland Road, Redlands, Bristol, Chemist and Soap Works Manager.
1891. Fraser, L. McG., Engineering Works, Dagenham, Essex, Chemical Engineer.
1902. Frederick, Geo. E., jun., 169, Columbia Heights, Brooklyn, N.Y., U.S.A., Chemical Merchant.
1916. Frenay, John L., The Works, Leagrave Road, Luton, Beds, Straw Dyer and Bleacher.
1900. French, Thos., P.O. Box 324, Nelson, B.C., Canada, Chemist.
1911. French, Wm., Wheatfield, Dallas Road, Lancaster, Manager and Secretary.
1903. Frerichs, Dr. F. W., 4320, Washington Boulevard, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1913. Frew, John, Box 1, Johannesburg, South Africa, Chemist.
1907. Freytag, Henry, 35 and 37, Dickinson Street, Manchester, Chemical Merchant.
1886. Fries, Dr. Harold H., 92 Reade Street, New York City, U.S.A., Chemical Manufacturer.
1915. Frosst, Charles E., 259, Metcalfe Avenue, Westmount, P.Q., Canada, Manufacturing Chemist.
1916. Frost, F. A., c/o South Metropolitan Gas Co., and 144, Fekham Park Road, London, S.E., Sub-Manager (Chemical Works).
1884. Frost, Joe, Rocky Mount, Somerset Road, Huddersfield, Manufacturing Chemist.
- O.M. Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.
1904. Fryer, P. J., 12, Pembury Road, Tonbridge, Kent, Analyst.
1889. Fuerst, Jos. F. See Forster, Jos. F.
1917. Fuerst, Jules, 17, Philpot Lane, London, E.C., Chemical Merchant.
1895. Fuerst, W. F., 87, Nassau Street, New York City, U.S.A., Chemical Merchant.
1913. Fulks, Elbridge B., American Tar Products Co., 208, South La Salle Street, Chicago, Ill., U.S.A., Vice-President.
1894. Fuller, Chas. J. P., 603, Chorley New Road, Horwich, near Bolton, Analytical Chemist.
1902. Fuller, Henry C., Institute of Industrial Research, Washington, D.C., U.S.A., Analytical Chemist.
- O.M. Fuller, Wm., Vanbrugh Cottage, Maze Hill, S.E., Chemist.
1916. Fulton, Chas. W., Rubber Tar Ltd., Bishopbriggs, Glasgow, Chemical Manufacturer.
1909. Fulweiler, W. H., 1706, North Broad Street, Philadelphia, Pa., U.S.A., Engineer.
1903. Fyelman, Dr. M. E., Kilmorna, Egmont Road, Sutton, Surrey, Chemist.
- G
1915. Gaby, F. A., Hydro-Electric Power Commission of Ontario, 150, University Avenue, Toronto, Canada, Chief Engineer.
1913. Gage, Roscoe M., 206, Rosalind Place, Toledo, Ohio, U.S.A., Chemical Engineer.
1906. Gagnebin, Chas. L., 140, Oliver Street, Boaton, Mass., U.S.A., Dyestuff Merchant.
1907. Gaines, Richard H., 49, Lafayette Street, New York City, U.S.A., Chemist (Board of Water Supply).
1912. Gajjar, M. J., Girgaum Chemical Laboratory, Sandhurst Road, Bombay, India, Consulting Chemist.
1890. Gajjar, Prof. T. K., Girgaum Chemical Laboratory, Sandhurst Road, Bombay, India, Consulting Chemist.
1912. Gale, Lieut. R. C., Mancot Royal, near Hawarden, Flintshire, Technical Chemist.
1884. Gall, Henry, 2, Rue Blanche, Paris, France, Technical Chemist.
1905. Gall, J. B., c/o Callender's Cable and Construction Co., Belvedere, Kent, Chemist.
1911. Gallagher, Jas. L., c/o Lever Bros. Ltd., Sydney N.S.W., Australia, Analytical Chemist.
1897. Galletly, J. C., No. 1, Staff Quarters, Eastriggs, Dornock, by Annan, Rubber Chemist.
1901. Gallivan, Dr. Frank B., 113, Third Street, South Boston, Mass., U.S.A., Chemist.
1903. Gallum, Albert F., 1000, North Water Street, Milwaukee, Wis., U.S.A., Tanner.
1901. Gallup, W. Arthur, Arnold Printworks, North Adams, Mass., U.S.A., Printer.
1901. Galpin, Harry T., 57, West 57th Street, New York City, U.S.A., Chemist.
1891. Galt, Hugh Allen, Columbia Chemical Co., Barberton, Ohio, U.S.A., Works Manager.
1894. Gane, Eustace H., 91, Filton Street, New York City, U.S.A., Pharmaceutical Chemist.
1901. Gansser, Dr. A., Albnang, 164, Basle, Switzerland, Chemical Engineer.
1916. Gant, Thos. H., 4, Victory Avenue, I.L.M. Factory, Gretna, Dumfriesshire, Explosives Chemist.
1911. Garbutt, C. Durlham, "Oakwood," 44, Long Lane, Garston, Liverpool, Analytical Chemist.
1910. Gardner, Arthur L., 126, West Chestnut Street, Wakefield, Mass., U.S.A., Chemical Engineer.
1907. Gardner, Edward, The Tryst, Bigwood Road, Meadway, Hendon, N.W., Metallurgical Chemist.
1909. Gardner, Henry A., 19th and B Streets N.W., Washington, D.C., U.S.A.
1891. Gardner, Prof. Walter M., Technical College, Bradford, Director of Chemical and Dyeing Departments.
1897. Garfield, Jos., Bank House, Apperley Bridge, near Bradford, Civil Engineer.
1910. Garland, Charles S., 57 Garratt Lane, Wandsworth, S.W., Chemist and Works Manager.
1911. Garner, John H., Sewage Works, Deighton, Huddersfield, Chemist.
1917. Garnett, Henry J., "Heathdene," Shoreham Road, Oxford, Kent, Chemist.
1915. Garrett, Dr. C. Scott, I.L.M. Factory, Bideford, Devon, Chemist.
1890. Garrett, Col. F. C., 27, Fern Avenue, Jesmond, Newcastle-on-Tyne, Teacher of Science.
1906. Garroway, Major John, 58, Buchanan Street, Glasgow, Chemist.
1908. Garson, Jas. W., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Managing Director.
- O.M. Garton, Sir Richard, Messrs. Hill, Garton, and Co., Southampton Wharf, Battersea, S.W., Glucose Manufacturer.
1886. Gascoyne, Dr. W. J., 27, South Gay Street, Baltimore, Md., U.S.A., Analytical Chemist.
- O.M. Gaskell, Holbrook, Erindale, Frodsham, Cheshire, Alkali Manufacturer.
1902. Gaskell, Holbrook, jun., Hillcroft, Church Road, Woolton, near Liverpool, Engineer.
1915. Ga'celiff, John, jun., 3, St. Andrew's Street, Rugby, Works Chemist.
1908. Gatehouse, Frank B., "Maristowe," Butts Green Road, Hornchurch, Romford, Chemist and Technical Journalist.
1912. Gates, Alfred E., c/o Messrs. T. Lyo and Sons, Luton, Beds, Works Chemist.
- O.M. Gathral, Geo., Beechwood, Sherbourne Road, Acocks Green, near Birmingham.
1906. Gaunt, Percy, Macclesfield Corporation Sewage Works, Prestbury, near Macclesfield, Chemist.
1917. Geary, Samuel T. T., Ellesmere, Littlemoor Hill, Smethwick, Works Chemist.
1912. Gee, Wm. J., 48, Kingsmead Road, Tulse Hill, London, S.W., Chemical Engineer.

1891. Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison Street, New York City, U.S.A., Consulting Chemist.
1901. Gemmell, G. H., 4, Lindsay Place, George IV Bridge, Edinburgh, Analytical Chemist.
1901. Gent, Percy W., Trentholme, Misterton, near Gainsboro', Chemist.
1897. Gent, Wm. T., Springfield, Misterton, near Gainsboro', Metallurgical Chemist.
1912. Georgeson, George, Stephen Court, 77-79, Elizabeth Street, Sydney, N.S.W., Manager of Oil Companies.
1913. Gepp, Herbert W., c/o Amalgamated Zinc (De Bavay's), Ltd., Broken Hill, N.S.W., Australia, General Manager.
1906. Gerkensmeyer, Henry H., 207, Mississippi Avenue, Joliet, Ill., U.S.A., Chemist.
1912. Ghislain, Raoul, Jefe de Fabricacion, Soc. Anon. des Fours a Coke Semet-Solvay du Nueva Montaña Compania 22, 2^a Izqda, Santander, Spain, Chemical Engineer.
1916. Ghose, A., c/o Mica Mining and Timber Co., and P.O., Ganwan, Dt. Hazaribagh, Prov. Behar, India, General Manager.
1911. Gibbings, W. Alan, P.O. Box Sannomiya 174, Kobe, Japan, Works Manager and Chemist.
1903. Gibbings, Wm., Woodside, Halebank, Widnes, Works Manager.
1910. Gibbins, Roland B., 18, Wheeley's Lane, Birmingham, Chemical Manufacturer.
1902. Gibbon, Edw., Belvedere, Park Road, Clydach, R.S.O., Glam., Works Chemist.
1915. Gibbon, John, The British Explosives Syndicate, Ltd., Factory, Pitsea, Essex, Chemist.
1904. Gibbs, A. E., c/o Pennsylvania Salt Manufacturing Co., Widener Building, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1913. Gibbs, Victor G., c/o Wm. Pearson, Ltd., Clough Road, Hull, Works Manager.
- O.M. Gibbs, Wm. P., 1, Dartmouth Park Avenue, London, N.W., Analytical Chemist.
1916. Gibson Prof. Charles S., The University Chemical Laboratory, Cambridge, Assistant to the Professor of Chemistry.
- O.M. Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, via Chester, Brick and Tile Manufacturer.
1905. Gibson, John, 360-366, Collins Street, Melbourne, Vic., Australia, Concrete Manufacturer.
1913. Gibson, R. M., 58, Chester Road, Buckley, via Chester, Clay Goods Manufacturer.
1905. Gibson, Wm. F., c/o Turner Bros. Asbestos Co., Ltd., Rochdale, Lancs., Works Chemist.
1914. Gidden, W. T., Woodside, Abbey Road, Smethwick, near Birmingham, Technical Chemist.
1916. Gifford, E. C., c/o British Dyes, Ltd., Turnbridge Works, Huddersfield, Technical Chemist.
1899. Gifford, Wm. E., 54, Austin Street, Newark, N.J., U.S.A., Chemist.
1892. Gilbard, J. Francis H., 245, Dalston Lane, Hackney, N.E., Analytical Chemist.
1905. Gilbertson, Isaac H., 33, Broad Street, Rhodes, near Middleton, Lancs., Calico Printer.
1903. Gilby, Joseph W., 11, Westfield Grove, Wakefield, Yorks, Works Chemist.
- O.M. Gilchrist, Percy Carlyle, F.R.S., Reform Club, Pall Mall, London, S.W., Metallurgist.
1884. Gilchrist, Peter S., Charlotte, N.C., U.S.A., Chemical Engineer.
900. Gildersleeve, W. H., Johnson City, Tenn., U.S.A., Chemist.
- O.M. Giles, W. B., The Grange, Leyton, Essex, Chemical Manufacturer.
1915. Giles, W. H., The Grange, Leyton, Essex, Manufacturing Chemist.
1886. Gill, Dr. Ang. H., Chemical Department, Massachusetts Institute of Technology, Cambridge, Mass., U.S.A., Professor of Technical Analysis.
1913. Gill, Harold W., Magadi Soda Co., Lake Magadi, British East Africa, Chief Resident Chemist.
1915. Gill, Hubert A., 55-56, Chancery Lane, London, W.C., Chartered Patent Agent.
1909. Gill, John H., 18, Fourth Avenue, Sherwood Rise, Nottingham, Soapworks Chemist.
1901. Gili, Wm. S., c/o Farquhar and Gill, North of Scotland Colour Works, Aberdeen, Paint and Varnish Manufacturer.
1901. Gilles, Wm. S., The Cottage, Bocking, near Braintree, Essex, Technical Chemist.
1917. Gilliam, Charles, Curtis and Harvey Explosives Works, Dartford, Kent, Chemist.
1888. Gillman, Gustave, 296 Avenida Sete Setembro, Petropolis, via Rio de Janeiro, Brazil, Civil Engineer.
1917. Gilmour, Dr. Robert, 40, Ulsterville Avenue, Belfast, Research Chemist.
1891. Gimmingham, Edw. A., Croyland, Clapton Common, N., Technical Electrician.
1906. Girtin, Thomas, H. L. Raphael's Refinery, 48, Thomas Street, Burdett Road, London, E., Bullion Refiner.
1903. Giadding, Thos. S., 181, Front Street, New York City, U.S.A., Analytical Chemist.
1906. Glass, A. Melville, "Copley Dene," Park Avenue, Hampstead, N.W., Patent Agent.
1894. Glen, Chas., Glengowan Printworks, Caldercruix, Scotland, Calico Printer.
1884. Glendinning, H., Winnington House, Northwich, Cheshire, Technical Chemist.
1917. Glossop, Arthur A., Lee Green, Cliffe-at-Hoo, Kent, Chemist.
1896. Glover, H., 6445, Emlen Street, Germantown, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.
- O.M. Glover, William, Albareda 27, Seville, Spain, Technical Chemist.
1911. Gmach, Ludwig T., Kew Bridge Label Works, Waldeck Road, Chiswick, W., Manufacturer.
1916. Godber, Geo. E., 86, Wellington Street, New Whittington, near Chesterfield, Chemist (Tar Products).
1911. Goetheius, John M., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Sales Manager.
1915. Goffin, Armand, Compagnie Commerciale du Nord, 126, Rue de Provence, Paris, Director.
1915. Golding, Geo., "Haverthwaite," Litherland Park, Liverpool, Analytical Chemist.
- O.M. Goldschmidt, Dr. S. A., 11, Broadway, New York City, U.S.A., President (Columbia Chemical Works).
1895. Goldsmith, Byron B., 19, East 74th Street, New York City, U.S.A., Vice-President (American Lead Pencil Co.).
1899. Goldsmith, Dr. Jno. N., 67, Chancery Lane, London, W.C., Chemist.
1914. Goldsmith, L. D., 31, Colvestone Crescent, West Hackney, N.E., Research Chemist.
1916. Goldstein, W., c/o The Asiatic Petroleum Co., Ltd., Portishead, Somerset, Works Chemist.
1906. Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.
1909. Goodban, Leonard, 43, Addison Gardens, Kensington, London, W., Works Chemist.
1912. Gooderham, J. Leys, 49, Wellington Street East, Toronto, Canada, Chemist.
1904. Gooding, E. Claude, Willow House, Washford, Somerset, Chemist. On active service.
1913. Goodman, Alexander, c/o Lever Bros., Ltd., Sunlight Wharf, Upper Thames Street, London, E.C., Manager.
1915. Goodman, V. E., c/o Waterlow and Sons, Ltd., 68-70, Worship Street, Finsbury, E.C., Manager of Cheque Department.
1898. Goodrich, Chas. C., 60, Broadway, New York City, U.S.A., Rubber Manufacturer.
1884. Goodwin, C. C., Racefield, St. Margaret's Road, Altrincham, Cheshire, Soapmaker.
1909. Goodwin, Capt. Camillo J., 60, Mark Lane, London, E.C., Chemical Engineer.

1913. Goodwin, H. W., c/o Charles Case and Sons, Westbury, Wilts, Analytical Chemist.
1903. Goodwin, Major Leo F., 46, Earl Street, Kingston, Ontario, Canada, Professor of Phys. Chemistry and Engineering.
1894. Goodwin, Dr. W. L., Library Dept., Gordon Hall, School of Mining, Kingston, Canada, Professor of Chemistry.
- O.M. Goppelsroeder, Prof. Dr. F., Leimenstrasse 51, Basel, Switzerland, Professor of Chemistry.
1884. Gordon, J. G., Queen Anne's Mansions, Westminster, S.W., Steel Manufacturer.
1904. Gotthelf, August H., Hastings-on-Hudson, N.Y., U.S.A., Chemist.
1914. Gotts, H. S., Corrison Works, Carnwarth Road, Fulham, S.W., Sugar Manufacturer.
1917. Gould clock, Wm. B. O'Brien, 46, Groslands Park, Barrow-in-Furness, Metallurgist.
1890. Goulding, The Right Hon. Sir Wm. J., Bart., c/o W. and H. M. Goulding, Ltd., Alexandra Road, East Wall, Dublin, Manure Manufacturer.
1917. Gower, Owen L., 20, Talbot Road, South Tottenham, N., Purchasing Agent and Manager.
- O.M. Gowland, Prof. W., F.R.S., 13, Russell Road, Kensington, W., Professor of Metallurgy (Royal School of Mines).
1890. Grabfield, Dr. J. P., c/o Morris and Co., Chemical Laboratory, Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1916. Grace, Claude S., 36, Harvard Road, Gunnersbury, W., Analytical Chemist.
1906. Graesser, Norman H., Chemical Works, Ruabon, N. Wales, Manufacturing Chemist.
1917. Grageroff, I., c/o Canadian Explosives, Ltd., Transportation Building, Room 82, Montreal, Canada, Chemical Engineer.
- O.M. Graham, C. C., Oriel House, Scarborough, Yorks, Technical Chemist.
1917. Graham, Charles W., 13, Prust Avenue, Toronto, Canada, Chemist.
1913. Graham, Jos. I., Chemical Laboratory, Bentley Colliery, Doncaster, Chemist.
1883. Grandage, H., c/o S. Smethurst and Sons, Ltd., Woolfold Dye and Bleach Works, Bury, Lancashire, Dyer.
1897. Granger, Dr. J. Darnell, c/o The Chiswick Polish Co., of Australia, Ltd., 338-356, Mitchell Road, Alexandria, N.S.W., Australia, Analytical Chemist.
1905. Grant, Alexander, 15, Hermitage Drive, Edinburgh, Baker.
1917. Grant, George, 56, Balmoral Avenue, Cathcart, Glasgow, Analytical Chemist.
1916. Grant, Robert, Microbiological Laboratory, Department of Public Health, Sydney, N.S.W., Bacteriologist.
1916. Grant, Wm., c/o Illinois Steel Co., Gary Works, Gary, Ind., U.S.A. (all comms. to 566, Maryland Street, Gary, Ind., U.S.A.), Chemist.
1896. Graves, Geo. H., 219, West 81st Street, New York City, U.S.A., Manufacturing Chemist.
1896. Graves, Walter G., 1950, East 90th Street, Cleveland, Ohio, U.S.A., Chemist.
1914. Gray, George, 3, Victoria Drive, Rock Ferry, Cheshire, Technical Chemist.
1884. Gray, G. Watson, 8, Inner Temple, Dale Street, Liverpool, Consulting Chemist and Assayer.
1911. Gray, Dr. G. W., The Midland Refining Co., El Dorado, Kansas, U.S.A., Chairman, Manufacturing Committee.
1910. Gray, H. Le Breton, c/o Eastman Kodak Co., Rochester, N.Y., U.S.A., Superintendent, Film Department.
1904. Gray, Jas., P.O. Box 5254, Johannesburg, Transvaal, Chemist.
1886. Gray, John, 3, Victoria Drive, Rock Ferry, near Birkenhead, Technical Chemist.
1901. Gray, J. Campbell, The Cottage, Strines, near Stockport, Printworks Chemist.
1916. Gray, Leslie R., 10, Palin Street, Hyson Green, Nottingham, Technical Chemist (Gerard Bros., Ltd.).
1896. Gray, Prof. Thos., Royal Technical College, Glasgow, Professor of Technical Chemistry.
1916. Gray, Thomas H., 52, Burford Road, Nottingham, Works Chemist (Gerard Bros., Ltd.).
1905. Gray, W. B., Messrs. Lever Bros., Durban, Natal, South Africa, Analytical Chemist.
1903. Gray, Wm. S., 76, William Street, New York City, U.S.A., Chemical Merchant.
1909. Greeff, R. H., Thames House, Queen Street Place, London, E.C., and (Jnls.) 80, Maiden Lane, New York City, U.S.A., Chemical Merchant.
1894. Greeff, R. W., Thames House, Queen Street Place, London, E.C., and (Jnls.) Elm Bank, Bromley, Kent, Chemical Merchant.
- O.M. Green, Prof. Arthur G., F.R.S., Municipal School of Technology, Whitworth Street, Manchester, (Journals to Holloway Clough, Arthog Road, Hale, Cheshire), Professor of Chemistry.
1907. Green, Clarence, c/o Nicholson's Raincoat Co., Beaumont Works, St. Albans, Herts, Chemist.
1906. Green, Ernest, 98, Cheadle Road, Cheadle Hulme, Cheshire, Science Teacher.
- O.M. Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
- O.M. Green, L., Lower Tovil, Maidstone, Paper Manufacturer.
1908. Green, Dr. W. Heber, Chemical Laboratory, The University, Melbourne, Victoria, Lecturer in Chemistry.
- O.M. Greenaway, A. J., The Orchard, Chertsey, Surrey, Sub-Editor of Chemical Society's Journal.
1915. Greene, F. A., 7, Alexandra Mansions, West End Lane, London, N.W., Consulting Engineer.
1909. Greenhough, George D., 21, Mincing Lane, London, E.C., Chemical Broker.
1913. Greenough, Thomas R., Beechwood, Leigh, Lancashire, Analytical Chemist.
1917. Greenwood, Dr. Harold C., 10, University Mansions, Putney, S.W., Research Chemist.
1907. Greenwood, Herbert W., c/o Backhouse and Coppock, Ltd., Sutton Mill, Macclesfield, Metallurgical Chemist.
- O.M. Greenwood, Holmes, Regent House, Hartmann Street, Accrington, Technical Chemist.
1907. Gregory, Joshua C., 3, Oak Villas, Bradford, Yorks, Analytical and Consulting Chemist.
1915. Greville, Henry, 57, Hamilton Square, Birkenhead, Research Chemist.
1890. Griffin, John R., Kenble Street, Kingsway, London, W.C., Chemical Apparatus Maker.
1886. Griffin, Martin L., c/o Oxford Paper Co., Rumford, Maine, U.S.A., Manager of Chemical and Electro-Chemical Department.
1912. Griffiths, Clement S., Central Queensland Meat Export Co., Ltd., Lake's Creek, Rockhampton, Queensland, Chemist.
1909. Griffiths, E., 136, George Street N., Sydney, N.S.W., Australia, Chemist.
1917. Griffiths, Hugh, c/o Bruce, Ward & Co., 41, Castle Street, Liverpool, Technical Chemist.
1902. Griffiths, Manfred E., Caizley House, Temple Road, Stowmarket, Suffolk, Explosives Chemist.
1916. Grigioni, J. L., c/o Antony Gibbs & Co., Antofagasta, Chile, South America, Consulting Chemical Engineer.
1912. Grinké-Drayton, Norman, Royal Mint Refinery, 19, Royal Mint Street, London, E., Metallurgist.
1917. Grimshaw, Harold B., 27, Wingfield Street, Gorse Hill, Manchester, Works Chemist.
1902. Grimwade, W. Russell, 335-343, Spencer Street, West Melbourne, Vic., Australia, Manufacturing Chemist.
1900. Grimwood, Robt. G., 43, Leaside Avenue, Muswell Hill, N., Analytical Chemist.
1905. Grip, August E., 495, Columbia Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1888. Gripper, Harold, Great Central Railway, Gorton, Manchester, Analytical Chemist.

1916. Grisley, Geo. C., 51, Henry Road, West Bridgford, Nottingham, Chemical Engineer.
1909. Grist, John M., c/o Curtis's and Harvey, Ltd., Explosives Works, Cliffe-at-Hoo, Kent, Explosives Chemist.
1906. Groenewoud, Sidney H., 12, Alexandra Road, Birmingham, Analytical Chemist.
- O.M. Grossmann, Dr. J., 157, Plymouth Grove, Manchester, Consulting Chemist and Chemical Engineer.
1896. Grosvenor, Dr. W. M., jun., Chemists' Building, 50, East 41st Street, New York City, U.S.A., Consulting Chemical Engineer.
1917. Grounds, Arthur, 10, Handfield Road, Waterloo, Liverpool, Chemist in Charge.
1909. Grove, Daniel, "Carmington," Canonbury Grove, Dulwich Hill, N.S.W., Australia; Diamond Buyer and Mine Owner.
- O.M. Groves, C. E., F.R.S., 352, Kennington Road, London, S.E., Chemist (Thames Conservancy).
1907. Groves, J. Stuart, c/o E. I. du Pont de Nemours Powder Co., City Point, Va., U.S.A., Chemist.
1899. Gudemann, Dr. E., 903, Postal Telegraph Building, Chicago, Ill., U.S.A., Chemist.
1915. Guelpa di Luigi, G., 41, Corso Dante, Turin, Italy, Manufacturer and Engineer.
1899. Guild, Frank N., University of Arizona, Tucson, Arizona, U.S.A., Professor of Chemistry.
1916. Guillaume, F. J., 736, Tower Building, Liverpool, Chemical Engineer.
1909. Gulliek, Wm. A., Government Printing Office, Sydney, N.S.W., Government Printer.
1906. Gulline, Percy, c/o Columbia Textile Co., Lowell, Mass., U.S.A., Agent.
1903. Gunn, Gilbert, Eastern Chemical Co., Ltd., Dharair, Bombay, Paper Mill Chemist.
1900. Gunther, Chas. E., Third Floor, Thames House, Queen Street Place, London, E.C., Merchant.
1910. Günther, C. M., Condong Mill, Tweed River, N.S.W., Sugar Chemist.
1903. Guthrie, Alan, The Leather Trades School, Washermupet, Royapuram, Madras, India, Leather Chemist.
1901. Guthrie, John M., 199, Ferry Road, Leith, Scotland, Analytical Chemist.
1909. Guttman, Camillo J. See Goodwin, C. J.
1903. Guttman, Dr. L. F. See Goodwin, Major Leo F.
1912. Guy, Wm. W., Melbourne House, Rowlands Gill, co. Durham, Analytical Chemist.
1916. Gwyer, Dr. A. G. C., c/o British Aluminium Co., Ltd., Research Laboratory, Warrington, Metallurgical Chemist.
1913. Gytton, Walter J., British Standard Cement Works, Rainham, Kent, Chemist.
- H**
1904. Hacking, D. H., Enfield Soap Works, Clayton-le-Moors, near Accrington, Soap Manufacturer.
1887. Hadfield, Sir Robert A., Bart., F.R.S., 22, Carlton House Terrace, London, S.W., Steel Founder.
1904. Hadley, Geo., 10, Waterfall Lane, Blackheath, Staffs, Spelter Works Manager.
1887. Haig, Robert, Dollarfield, Dollar, Scotland, Chemical Engineer.
1915. Haigh, Alfred, c/o Britains Ltd., Cheddleton Paper Mills, near Leek, Staffs., Paper Manufacturer.
1904. Haigh, B. Wilson, By-Product Coke Oven Dept., Barnsley Main Colliery, Barnsley, Yorks, Chemical Engineer.
1896. Haigh, De Lagnel, 381, Fourth Avenue, New York City, U.S.A., Chemist.
1915. Haigh, Sam, 89, Johnson Avenue, Winthrop, Mass., U.S.A., Dyer and Chemist.
1888. Hailes, A. J. de, 15, Red Lion Square, London, W.C., Analytical Chemist.
1910. Hailstone, Harold J., 44, Cordley Street, West Bromwich, Works Chemist.
- O.M. Hake, C. Napier, Jnls. to c/o Dr. A. W. Hake, Medical School, Caxton Street, Westminster, S.W., Chemical Adviser.
1903. Halbert, Thos., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.
1888. Hale, Edw. P., Park End, Minthorpe, Westmorland, Analytical Chemist.
1917. Haley, George A., 42, Lansdowne Road, West Didsbury, Manchester, Technical Chemist.
1898. Hall, Clarence A., Pelham Court, Germantown, Philadelphia, Pa., U.S.A., Chemist.
1917. Hall, Edwin A., 55, Somerville Road, Waterloo, Liverpool, Analytical Chemist.
1909. Hall, Harold, Chem. Laby., Loco. Dept., S.E. & C Rly., Ashford, Kent, Analyst.
1916. Hall, John H., Departure Bay, B.C., Canada, Superintendent High Explosives Works.
1912. Hall, Robert H., Weardale Tar Works, Spennymoor, Co. Durham, Chemical Works Manager.
1896. Hall, Capt. S. Godfrey, East London Soap Works, Bow, E., Soap Maker.
1914. Hall, William A., Hall Motor Fuel, Ltd., Wilson's Wharf, Angel Road, Edmonton, N., Chemical Engineer.
1886. Haller, Geo., Sussex House, 52, Leadenhall Street, London, E.C., Chemical Merchant.
1893. Haller, H. Loft, 26, Scale Lane, Hull, Analytical Chemist.
1912. Hallday, McDonald, 6, Oficina Carmen Bajo, Iquique, Chile, Analytical Chemist.
1895. Halliwell, Edw., c/o Ribble Joint Committee, 2, Stanley Place, Preston, Chief Inspector.
1892. Hamaguchi, Gihei, Maedachō, Choshi Chibaken, Japan, Soy Manufacturer.
1897. Hamby, Fred J., Buckingham, Quebec, Canada, Chemist.
1901. Hambuechen, Carl, 4, Pennsylvania Avenue, Belleville, Ill., U.S.A., Secretary (American Carbon and Battery Co.).
1915. Hamilton, David, 31, Newlands Road, Newlands, Glasgow, Analytical Chemist.
1911. Hamilton, David J., Locksley, Helensburgh, Dumbartonshire, Oil Refiner and Paint Manufacturer.
1904. Hamilton, Edward H., c/o The Consolidated Mining and Smelting Co. of Canada, Ltd., Trail, B.C., Canada, Metallurgist and Engineer.
1912. Hamilton, James, 9, Esplanade Avenue, Whitley Bay, Northumberland, Analytical Chemist.
1917. Hamilton, James H., 707, Yorkshire Building, Vancouver, B.C., Canada, Technical Journalist.
1884. Hamilton, Robert, Glengarnock Chemical Co., Ltd., Glengarnock, Ayrshire, Works Manager.
1892. Hamilton, Robt., Jnl. to c/o Walter Scott, Ltd., Leeds Steel Works, Leeds, Analytical Chemist.
1917. Hamilton, Robt., junr., 24, Old Side, Workington, Analytical Chemist.
1898. Hammersley, W. Stanley, Rue Champbertrand, Sens (Yonne), France, Tanner.
- O.M. Hammill, M. J., The Gables, St. Helens, Alkali Manufacturer.
1917. Hampson, Harry, c/o Levinstein Ltd., Blackley, Manchester, Works Chemist.
1905. Hancock, Thos. J., Chemist. Retain Journal's.
1900. Hancock, Walter C., 10, Upper Chadwell Street, Myddelton Square, London, E.C., Chemist.
1896. Hand, Daniel, 30, Mount Pleasant Avenue, Newark, N.J., U.S.A., Chemist.
1888. Hanks, Abbot A., 630, Sacramento Street, San Francisco, Cal., U.S.A., Assayer.
1916. Hannay, Jas. R., Knowmill House, Entwistle, near Bolton, Printworks Manager.
1905. Hanson, H. Norman, The Oaks, Huddersfield Road, Brighouse, Yorks, Research Assistant.
1908. Hanson, W. G., c/o United States Glue Co., Milwaukee, Wis., U.S.A.
1909. Harbord, F. W., 16, Victoria Street, Westminster, S.W., Consulting Metallurgist.
1905. Harcourt, Prof. R., Ontario Agricultural College, Guelph, Ont., Canada, Professor of Chemistry.
1904. Hard, Dr. James M. B., 422, Gravier Street, New Orleans, La., U.S.A., Chemist and Pathologist.

1901. Harcastle, G. Fred., 307, East Park Road, Leicester, Teacher of Science and Technology.
1894. Harden, Dr. Arthur, F.R.S., 5, Cambridge Gardens, Marlborough Road, Richmond, Surrey, Lecturer in Chemistry.
1910. Hardie, Thos., Newcastle and Gateshead Gas Co., Tyneside Road, Newcastle-on-Tyne, Gas Engineer.
1915. Harding, Cpl. Gilbert (on Active Service, Journals to 47, Buttermarket Street, Warrington), Chemist.
1912. Hardwick, Walter A. N., 26, West Kensington Mansions, London, W., Chemist.
1900. Hardwick, W. Roscoe, 13, Batavia Buildings, Hackins Hey, Liverpool, Chemist.
1905. Hardy, Chas. H., 16, Westbourne Avenue, Hull, Chemist.
1913. Harger, Dr. John, Grange Hollies, Gateacre, Liverpool (Journals to Chemical Labv., University College, Gower Street, London, W.C.).
1914. Hargreaves, C. H., Hilton, Court Hill, Banstead, Surrey, Analyst.
1906. Hargreaves, F., c/o Brimsdown Lead Co., Ltd., Brimsdown, Middlesex, Chemist.
1916. Hargreaves, Harry, 137, Whalley Road, Acerington, Lanes, and Corporation Electricity Works, Chemist.
- O.M. Hargreaves, Jno., Widnes, Alkali Manufacturer.
1904. Harker, Dr. George, Dept. of Organic Chemistry, The University, Sydney, N.S.W., Australia, Chemist.
1909. Harland, Robert M., 37, Lombard Street, London, E.C., Analytical Chemist and Assayer.
1893. Harlock, E. B., Newton House, Middlewich, Chemical Manufacturer.
1916. Harlow, L. C., Agricultural College, Truro, Nova Scotia, Chemist.
1905. Harper, Dr. Henry W., University of Texas, 2216, Rio Grande Street Austin, Texas, U.S.A., Professor of Chemistry.
1912. Harper, J. G., Kynochtown, Stanford le Hope, Essex, Managing Chemist.
1913. Harper, William, 3, Gindera Cottages, Montrose, Scotland (Journals to c/o Lever Bros. (Japan) Ltd., Sannomiya, P.O. Kobe, Japan), Works Chemist.
1912. Harran, Dr. Edward B., Abbey Field, Sandbach, Cheshire, Chemist.
1885. Harris, Booth, jun., "Diconwyn," Woodford Green, Essex, Soap Maker.
1897. Harris, Fred. W., 20, Trongate, Glasgow, Public Analyst.
1915. Harris, John, "York House," 8, Main Road, Handsworth, Sheffield, Metallurgist.
1906. Harris, Jonathan W., c/o Western Electric Co., 463, West Street, New York City, U.S.A., Chemist.
1914. Harris, Joseph H., 994, Danforth Avenue, Toronto, Canada, Superintendent.
1907. Harris, Thos. E., c/o The Union Acid Co., 17, Cooper Street, Manchester, Chemical Merchant.
1906. Harris, Wm. G., jun., 35, Fraser Avenue, Toronto, Canada, Metallurgist.
1916. Harrison, Charles, 137, Avondale Square, Old Kent Road, S.E., Lecturer.
1905. Harrison, E. F., Langholm, Edgar Road, South Croydon, Analytical Chemist.
1883. Harrison, G. Herbert, Hagley, Stourbridge, Firebrick Maker.
1892. Harrison, Prof. John B., C.M.G., Government Laboratory, Georgetown, British Guiana, Government Analyst.
1907. Harrison, W., 28, Delfh Lane, Hyde Park, Leeds, and (Juls.) Fuel Dept., The University, Leeds, Technical Investigator.
1896. Hart, Bertram, Oakfield Cottage, Stamford Road, Bowdon, Cheshire, Analyst.
1886. Hart, Bertram H., Rosslyn, High Street, Sidcup, Kent, Analytical Chemist.
- O.M. Hart, Dr. E., Gayley Hall, Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.
1890. Hart, H. W., Garth, Clifton Drive, Lytham, Lancashire, Analytical Chemist.
1916. Hart, Samuel H., Monnt Ngwibi, via Vryheid, Natal, Technical Chemist and Works Manager.
1897. Hart, Wm. Beamont, Manchester Laboratory, 8, Exchange Street, Manchester, Consulting Chemist.
1908. Hartley, Bernard C., 56, Wood View, Manningham, Bradford, Analytical Chemist.
1912. Hartley, Harold, c/o The Richmond Gas Stove and Meter Co., Ltd., Warrington, Research Chemist.
1883. Hartley, Joseph, 73, East Road, Stockport Road, Longsight, Manchester, Technical Chemist.
1912. Hartley, Thos., 64, Westleat Road, Swindon, Wilts., Teacher of Technical Chemistry.
1905. Hartshorne, Wm. D., Arlington Mills, Methuen, Mass., U.S.A., Agent.
1901. Hartwell, S. Warren, 825, Papinosa Avenue, Easton, Pa., U.S.A., Chemist.
1917. Harvey, Arthur, 12, Chaldon Road, Fulham, London, S.W., Analytical Chemist.
1908. Harvey, Arthur J., 18, Shochbury Road, East Ham, E., Chemist.
1885. Harvey, Ernest W., 36, Arthur Road, Wimbledon Park, London, S.W., Engineer.
1899. Harvey, Thos. F., 5, Park Hill Road, Chingford, Essex, Analyst (Drug Co.).
1916. Harwood, H. E., Royal College of Science, South Kensington, S.W., Teacher of Chemistry.
1906. Haskell, Walter F., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.
1900. Haslwanter, Chas., 447, Spruce Street, Richmond Hill, Long Is., N.Y., U.S.A., Analytical Chemist.
1897. Hasslacher, Jacob, P.O. Box 1999, New York City, U.S.A., President, Roessler-Hasslacher Chemical Co.
1916. Hastings, John Wm., 284, Paisley Road West, Glasgow, Chemist.
1903. Hatschek, Emil, c/o S. Bornett and Co., Ltd., 19, St. Dunstan's Hill, London, E.C., Engineer.
1887. Hatton, Wm. P., c/o W. R. Hatton and Sons, Wormwood Scrubbs, W., Starch Works Manager.
1915. Hattori, T., c/o Institute of Science, Taipei, Formosa, Japan, Chemical Expert.
1906. Hattrick, John M., c/o Board of Agriculture, Food Production Department, 72, Victoria Street, Westminster, S.W., Potash Agent.
1916. Haunton, Alfred, 41, Junction Road, Romford, Essex, Technical Chemist.
1906. Havercroft, Arthur E., Glenholme, Westbourne Road, Hornsea, Yorks, Chemist.
1916. Haviland, Edwin, Maxa Ltd., 43, Cannon Street, London, E.C., Manager.
1899. Hawdon, H. S., Cleadon, near Sunderland, Chemical Works Manager.
1895. Hawker, E. W., Gladstone Chambers, Adelaide, South Australia, Metallurgist.
1910. Hawkes, Cornelius A., "Eastnor," Tuffley Crescent, Gloucester, Analytical Chemist.
1902. Hawkins, Clement C., c/o The Texas Co., Port Neches, Texas, U.S.A., Chemist.
1897. Hawkins, Ernest M., Watling Chambers, Canterbury, Analytical Chemist.
1905. Hawkins, Henry, Moyola Villa, Lansdown, Limerick, Ireland, Gas Engineer.
1887. Hawliczek, Dr. Josef E., c/o United Alkali Co., Ltd., Intelligence Dept., Widnes Consulting Technical Chemist.
1899. Haworth, Dr. Edw., Beaconsbury, Weston Road, Runcorn, Cheshire, Chemist.
1910. Haworth, John, Sewage Disposal Works, Wincobank, Sheffield, Chemist and Sewage Works Superintendent.
1916. Haworth, Dr. W. N., Scores Villa West, St. Andrews, Scotland, Reader and Lecturer in Chemistry.
1904. Hawthorn, J. H., Municipal Technical School, Leicester, Head Master.
1915. Hay, Alex. H., Essex Wharf, Narrow Street, Limehouse, E., Caramel Manufacturer.
1914. Hay, George S., "Westbrook," 30A, Marriott Road, Tollington Park, London, N., Analytical Chemist.

1915. Hay, William, 121, St. Vincent Street, Glasgow, Secretary.
1909. Haydon, James R., Laboratory, 30, Norfolk Street, Liverpool, Works Manager and Chemist.
1916. Hayhurst, W., "Woodlands," Accrington, Technical Chemist.
1894. Haynes, David O., 3, Park Place, New York City, U.S.A., Proprietor, "Pharmaceutical Era."
1902. Hays, B. F., c/o E. R. Squibb and Sons, 80, Beekman Street, New York City, U.S.A., Pharmaceutical Chemist.
1906. Hayworth, W. P., 24, Tower Road, Dartford, Kent, Chemist.
1905. Hazard, Fred R., P.O. Box 2, Syracuse, N.Y., U.S.A., President (Solvay Process Co.).
1903. Hazen, Chas. R., 258, Prince Albert Avenue, Westmount, Quebec, Canada, Chemist.
1894. Heal, Carlton B., Hill Crest, Runcorn, Cheshire, Tanner.
1912. Healey, E., jun., St. Mary's Mills, Leicester, India-rubber Manufacturer.
1905. Heathcote, Henry L., c/o Rudge-Whitworth, Ltd., Coventry, Research Chemist.
1917. Heaven, George S., Templemead, Albany Road, Coventry, Engineer Chemist.
1905. Heberlein, Dr. Edw., c/o H. T. Enthoven and Sons, Ltd., 247, Rotherhithe Street, London, S.E., Works Manager.
1889. Hecht, Jos. L., c/o French and Hecht, Davenport, Iowa, U.S.A., Analytical Chemist.
1900. Heckman, J. Conrad, Larkin Soap Manufacturing Co., Seneca Street, Buffalo, N.Y., U.S.A., Chemist.
1914. Hector, Alex. B., c/o Burroughs, Wellcome and Co., 481, Kent Street, Sydney, N.S.W., Australia, Manager.
1912. Hedley, Dr. Edgar P., c/o Mrs. Alenby, Fernbank, 61, Derby Road, Borrowash, near Derby, Chemist.
- O.M. Hehner, Otto, 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.
1914. Heinemann, Dr. A., The D.R. Syndicate, Ltd., Ryders Green, West Bromwich, Research Chemist.
1887. Hellier, E. A., Avonside Varnish Works, St. Philip's Marsh, Bristol, Varnish Manufacturer.
1885. Hellon, Dr. R., 40, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.
1903. Helps, D. H., c/o Reading Gas Co., King's Road Works, Reading, Engineer and Manager.
1898. Hemingway, Frank C. R., 1, Broadway, New York City, and (Jnls.) 6, East Union Avenue, Bound Brook, N.J., U.S.A., Chemical Manufacturer.
1883. Hemingway, H., 9, Albemarle Mansions, Heath Drive, Hampstead, N.W., Chemical Manufacturer.
1903. Hemstreet, George P., Hastings-on-Hudson, N.Y., U.S.A., Mechanical Engineer.
1910. Henderson, Ernest G., c/o Canadian Salt Co., Ltd., Windsor, Ont., Canada, Vice-President and Manager.
1883. Henderson, Prof. G. G., F.R.S., Royal Technical College, Glasgow, Professor of Chemistry.
1902. Henderson, Dr. Jas. A. Russell, 21, Irlain Road, Sale, Cheshire, Professor of Chemistry and Physics.
1894. Henderson, Norman M., Broxburn Lodge, Broxburn, Scotland, Oil Works Manager.
1915. Henderson, T. A., 140, Keewatin Avenue, Toronto, Canada, Chemical Works Manager.
- O.M. Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.
1893. Hendrick, Prof. Jas., Marischal College, Aberdeen, Professor of Agriculture.
1906. Henius, Dr. Max, 1135-1147, Fullerton Avenue, Chicago, Ill., U.S.A., Secretary, Brewers' School.
1912. Henley, Andrew T., Lady's Well Brewery, Cork, Ireland, Technical Chemist.
1904. Henley, Hon. F. R., 49, Montagu Square, London, W., Brewer's Chemist.
1905. Henning, Albert, c/o Hedley and Co., 92, Harrow Road, Leytonstone, N.E., Chemical Manufacturer.
1906. Henning, C. I. B., c/o E. I. du Pont de Nemours Powder Co., Experimental Station, P.O. Henry Clay, Del., U.S.A., Chemist.
1914. Henshaw, D. M., c/o W. C. Holmes and Co., Ltd., Whitestone Ironworks, Huddersfield, Chemical Engineer.
1894. Henshaw, Sam., Glenthorpe, Wolstanton, Stoke-on-Trent, Chemical Works Manager.
1916. Heon, Alfred A., c/o Vancouver Milling and Grain Co., Ltd., 236, Smythe Street, Vancouver, B.C., Canada, Chemist.
1910. Hepburn, Edward, Priory Works, Dartford, Kent, Tanner.
1888. Hepworth-Collins, W., Junior Constitutional Club, Piccadilly, W., Civil Engineer.
1917. Herbert, Alfred E., 21, Fitzwilliam Street West, Huddersfield, Works Chemist.
1914. Herdsman, Frank, 144, Wellington Street, Glasgow, Consulting Chemist and Metallurgist.
1906. Herig, Harry W., c/o General Chemical Co., Hudson River Works, Edgewater, N.J., U.S.A., Chemist.
1897. Heriot, T. H. P., Royal Technical College, Glasgow, Lecturer on Sugar Manufacture.
1916. Heritage, C. C., 452, Auburn Avenue, Buffalo, N.Y., U.S.A., Assist. Manager.
- O.M. Herman, W. D., Holm Lea, Rainhill, Lancashire, Glass Works Chemist.
1917. Heron, Harold, 110, Fenchurch Street, London, E.C., Analytical and Consulting Chemist.
1903. Herreshoff, J. B. F., 620, West End Avenue, New York City, U.S.A., Chemical Engineer.
1887. Herriot, Wm. Scott, Clarewood, Thorntonhall, Lanarkshire, Mechanical Engineer.
- O.M. Herrmann, R. W., 59, Mark Lane, London, E.C., Chemical Merchant.
1891. Hersam, Ernest A., University of California, Berkeley, Cal., U.S.A., Associate Professor of Metallurgy.
1898. Hersey, Dr. Milton L., P.O. Box 1036, Montreal, Canada, Consulting Chemist.
1906. Herty, Prof. Chas. H., 35, East 41st Street, New York City, U.S.A., Professor of Chemistry.
1916. Hess, Julius, c/o Adolph Hess and Bro., Ltd., Oil Works, Kirkstall Road, Leeds, Oil Distiller and Refiner.
1891. Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.
1910. Hewitt, Arthur, c/o Consumers' Gas Co., 19, Toronto Street, Toronto, Canada, General Manager.
1896. Hewitt, Dr. J. Theo., F.R.S., Clifford House, Bedford, Middlesex, Lecturer.
1890. Hewlett, John C., 40-42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.
1907. Hewson, Geo. W., Grasmere, Field Terrace, Jarrow-on-Tyne, Analytical Chemist.
1893. Hey, Harry, 2, Ash Terrace, Saville Town, Dewsbury, Dyer.
1894. Heyl, G. Edward, 61-62, Lincoln's Inn Fields, London, W.C., Chemical and Electrical Engineer.
1906. Heys, Charles H., Toronto Arcade, Toronto, Canada, Consulting Chemist.
1915. Hibbert, Gilbert S., Buckton Vale Print Works, Stalybridge, Cheshire, Printworks Manager.
1906. Hicking, Sir W. Norton, Bart., Queen's Road Works, Nottingham, Lace Dresser.
1906. Hickman, T. Moore, Oakleigh, Tettenhall Wood, Wolverhampton, Analyst.
1897. Hicks, Edwin F., 4837, Fairmount Avenue, Philadelphia, Pa., U.S.A., Chemical Engineer.
- O.M. Higgin, W. H., c/o C. J. Schofield, Ltd., Alkali Works, Clayton, Manchester, Chemical Manufacturer.
1913. Higgins, A. Howard, Estrella, Hale Lane, Mill Hill, London, N.W. (Journals to c/o Minerals Separation Ltd., 62, London Wall, E.C.), Metallurgist.
1915. Higgins, C. A., c/o G. M. Norman, Hercules Powder Co., Du Pont Building, Wilmington, Del., U.S.A., Works Chemist.
1886. Higgins, C. L., 41, Knowsley Road, Cressington Park, Liverpool, Manufacturing Chemist.
1908. Higgins, S. H., Lunceary Bleachfield, Perth, Chemist and Asst. Manager.

1909. Higson, Frank, 52, Chapel Street, Salford, Manchester, Analytical Chemist.
- 1909 Higuchi, Ken-ichi, Central Laboratory, South Manchuria Railway Co., Dairen, Manchuria, Chemical Engineer.
1917. Hinkins, George H., 28, Hornby Road, Old Trafford, Manchester, Chemical Engineer.
1911. Hidditch, T. P., Birchdene, Cross Lane, Grappenhall, Warrington, Research Chemist.
1903. Hill, Chas. Alex., c/o British Drug Houses, Ltd., 22-30, Graham Street, City Road, N., Chemist.
1917. Hill, Edgar, 36, Mysore Road, Clapham Common, S.W., Chemist.
1916. Hill, George Norman, c/o Imperial Varnish and Colour Co., 8/20, Morse Street, Toronto, Canada, Chemist.
1897. Hill Dr. Herbert M., 20, West Eagle Street, Buffalo, N.Y., U.S.A., City Chemist.
1907. Hill, James A., 8, Highfield Crescent, Rock Ferry, Cheshire, Technical Chemist.
1908. Hill, J. H. F., Ministry of Munitions, Dept. of Explosives Supply, Acid Section, Queen Anne's Chambers, Westminster, London, S.W., Superintendent, Coke and By-Product Plant.
1916. Hill, Jas. W., Box 218, Banff, Alberta, Canada, Industrial Chemist.
- O.M. Hill, J. K., 13, Osborne Place, Ibrox, Glasgow, Manufacturing Chemist.
1915. Hill, J. Rutherford, 36, York Place, Edinburgh, Pharmaceutical Chemist.
1892. Hill, Sydney, c/o Blundell, Spence, and Co., Ltd., Hull, Analytical Chemist.
1903. Hill, W. Basil, Foss Islands Tannery, York, Tanner.
1894. Hills, Harold F., Commercial Gas Works, Stepney, London, E., Analytical Chemist.
- O.M. Hills, W., Oxford Works, Tower Bridge Road, London, S.E., Pharmaceutical Chemist.
1899. Hinchley, J. W., 55, Redcliffe Road, London, S.W., Chemical Engineer.
1904. Hinchley, J. F., 550, East 7th Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
- O.M. Hindle, J. H., 8, Cobham Street, Accrington, Dyeworks Manager.
1916. Hindley, Edward, jun., The Poplars, Barnton, near Northwich, Cheshire, Phosphate Manufacturer.
1909. Hinks, Edward, 16, Southwark Street, London, S.E., Analyst.
1899. Hinks, Percy J., Danger Building Dept., Royal Laboratory, Woolwich Arsenal, S.E., Chemist.
1891. Hinman, Bertrand C., Coventry House, South Place, Finsbury, London, E.C., Metallurgical Chemist.
1909. Hirsch, Fritz, 44, Rothwell Road, Gosforth, Newcastle-on-Tyne, Analytical Chemist.
1914. Hirst, A. Norman, Box 1141, Durban, South Africa, Consulting Chemist.
1895. Hirst, H. Reginald, c/o Geo. H. Hirst and Co., Ltd., Victoria Mills, Savell Town, Dewsbury, Works Chemist.
1907. Hirt, Wilhelm B., c/o Cumming, Smith, and Co., Ltd., Yarra Junction, Vic., Australia, Analytical Chemist.
1916. Hiscock, W. G., c/o New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.
1896. Hislop, Geo. R., (Journals) Gas Works, (Communications) Greenhill House, Underwood Road, Paisley, Gas Engineer and Manager.
1915. Hitch, E. F., Equitable Powder Manufacturing Co., East Alton, Ill., U.S.A., Chemist.
1913. Hitchcock, Thos. J., 28, Albany Road, Manor Park, Essex, Technical Chemist.
1915. Hitchins, A. B., Research Laboratory, Anseo Co., Binghamton, New York, U.S.A., Research Chemist.
1917. Hitchman, Fredk. G., 50, Cranmer Street, Nottingham, Analytical Chemist (Boots Pure Drug Co.).
1906. Hobsbaum, I. B., c/o Messrs. Anthony Gibbs & Sons, 22, Bishopsgate, London, E.C., Analytical Chemist.
1905. Hobson, Alfred, Dantzic Brewery, Imperial Street, Regent Street, Leeds, Brewer and Wine Manufacturer.
1916. Hockin, Daniel, 796, Beatty Street, Vancouver, B.C., Canada, Wholesale Druggist.
1894. Hodger, Andrew, "Wilford," 16, Clifton Road, Heaton Moor, near Stockport, Printworks Chemist.
1913. Hodgetts, E. A. Brayley, 36, Elvaston Place, Queen's Gate, S.W.
1915. Hodgkinson, S. E., 5, Taylor Street, Heaton Park; Manchester, Works Analyst.
- O.M. Hodgkinson, Dr. W. R., 89, Shooter's Hill Road, Blackheath, S.E., Professor of Chemistry.
1913. Hodgson, Cyril V., 57, St. George's Avenue, Southlands, Wolstanton, Stoke-on-Trent, Works Chemist.
1917. Hodgson, Joseph P., 1573, Main Street, Vancouver, B.C., Canada, Chemical Manufacturer.
1897. Hodgson, Matthew, The Murrrough, Wicklow, Ireland, Technical Chemist.
1890. Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.
1910. Hodsman, Henry J., Dept. of Fuel and Coal Gas Industries, The University, Leeds, Chemist.
1917. Hodson, Thos., c/o Levinstein, Ltd., Blackley, Manchester, Works Chemist.
1906. Hogarth, Julius W., H.M. Guncotton Factory, Colnbrook, near Staines, Middlesex, Demonstrator of Chemistry.
1886. Hogben, W., 71, Leamington Terrace, Edinburgh, Celluloid Works Manager.
1916. Hogg, Charles, 8, Cadogan Street, Glasgow, Chemical Broker.
1917. Hogg, Stuart, c/o Chas. Butters & Co., Ltd., 54, New Broad Street, E.C., Director.
1905. Holcroft, Harold, Parkdale, Wolverhampton, Iron-founder.
1916. Holden, Geo. E., 29, Durnford Street, Middleton, Lanes, Dyeworks Chemist.
1887. Holden, G. H., Manchester Oxide Co., Ltd., Canal Street, Miles Plating, Manchester, Chemist.
1904. Holden, Norman N., c/o Hardman and Holden, Ltd., Miles Plating, Manchester, Manufacturing Chemist.
1916. Holdredge, Leigh I., c/o Hilton Trading Co., 136, Liberty Street, New York City, U.S.A., Chemical Engineer.
1902. Holdsworth, Ernest T., "Holme Dene," Crossley Hall, Bradford, Dyer.
1885. Holgate, T. E., 173, Hollins Grove, Darwen, Lancashire, Metallurgist.
- O.M. Holland, Philip, 22, Taviton Street, Gordon Square, London, W.C., Analytical Chemist.
1892. Holland, Philip H., 546, Sherbrooke Street West, Montreal, Canada, Merchant.
1915. Hollings, Harold, 1, Northwood Road, Forest Hill, S.E., Technical Chemist.
1896. Hollings, J. Spencer, Brymbo, North Wales, Works Manager.
1917. Hollingsworth, C., "Brooklyn," Broomfield Road, Chadwell Heath, Essex, Analytical Chemist.
1909. Hollingsworth, David V., Birchenwood Collieries, Kidsgrove, Stoke-on-Trent, Gas Analyst.
1917. Hollins, Cecil, 43, Stapleton Road, Balham, London, S.W., Chemist.
1903. Hollinshead, Peter, The Beeches, Weston Road, Runcorn, Cheshire, Chemist.
1900. Hollinshead, Dr. Warren H., 1606, Belcourt Avenue, Nashville, Tenn., U.S.A., Teacher of Chemistry.
1904. Holloway, E. G., c/o Jas. S. Kirk and Co., 360, North Water Street, Chicago, Ill., U.S.A., Chemist.
1890. Holloway, G. T., 9-13, Emmett Street, Limehouse, London, E., Chemist and Metallurgist.
1916. Holmes, C. E., 64, Harrington Road, Workington, Chemist.
1883. Holmes, Ellwood, Wyncote, Jesmond Park East Newcastle-on-Tyne, Colour Manufacturer.
- O.M. Holmes, F. G., Thames Tar Works, Lower Road, Northfleet, Kent, Tar and Ammonia Distiller

1914. Holroyd, Thomas A., c/o Levinstein, Ltd., Blackley, Manchester, Colour Chemist.
1913. Holt, Dr. Alfred, Dowsefield, Allerton, Liverpool, University Reader in Physical Chemistry.
1900. Holthouse, Harold B., 106, Radcliffe Road, West Bridgford, Nottingham, Chemist.
1902. Holton, Alf. L., Chemical Dept., Gas Works, Bradford Road, Manchester, Chemist.
1892. Holton, E. C., 601, Canal Road, N.W., Cleveland, Ohio, U.S.A., Chemist.
1893. Holzapfel, Max, c/o Holzapfels, Ltd., Felling-on-Tyne, Manufacturer.
1916. Home, James, 17/19, St. Therese Street, Montreal, Canada, Paper Maker.
1893. Homfray, D., c/o The Hard Chemical Co., Santa Julia, Mexico City, Analytical Chemist.
1909. Hook, Russell W., 8, Holton Street, West Medford, Mass., U.S.A.
1904. Hooker, A. H., c/o Hooker Electrochemical Co., Niagara Falls, N.Y., U.S.A., Manufacturing Chemist.
- O.M. Hooper, E. Grant, 16, Royal Avenue, Sloane Square, London, S.W., Analytical Chemist.
1889. Hooper, Ernest F., Pilgrim House, Pilgrim Street, Newcastle-on-Tyne (Journals to "The Hill," Stroud, Glos.), Technical Chemist.
1888. Hope, Jas., The Knoll, Lenzie, near Glasgow, and (Journals) The Nickel Co., Kirkintilloch, by Glasgow, Nickel Works Manager.
1904. Hopewell, Fredk., 8, Place Youville, Montreal, Canada, Manager.
1892. Hopkins, Erastus, 21, Arnold Park, Rochester, N.Y., U.S.A., Consulting Chemical Engineer.
1915. Hopkins, E. M., c/o Thos. Jackson, Chemical Works, Clayton, Manchester, Manager and Chemist.
1905. Hoppstedt, A. W., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Chemist.
1895. Horne, Dr. W. D., 175, Park Avenue, Yonkers, N.Y., U.S.A., Consulting Chemist.
1904. Hornsey, J. W., 233, Broadway, New York City, U.S.A., and (Journals) Summit, N.J., U.S.A., Chemical Engineer.
1913. Horrocks, Herbert, 147, Wegman Parkway, Jersey City, N.J., U.S.A., Chemist.
1914. Horrocks, John M., "Maywood," Osborne Road, Levenshulme, Manchester, Tar Distiller and Manufacturing Chemist.
1900. Horsfall, John, 4, Grange Avenue, Rawtenstall, Manchester, Analytical and Consulting Chemist.
1917. Horsfall, Ronald S., c/o Levinstein, Ltd., Blackley, Manchester, Chemist.
1901. Horton, Edw., jun., Rothamsted Experimental Station, Harpenden, Herts, Chemist.
1916. Hose, Dr. Chas., The Lodge, Botesdale, Diss; (Jnls.) H.M. Factory, King's Lynn, Norfolk, Acetone Manufacturer.
1906. Hoseason, Jas. H., Sun Buildings, 2, Bridge Street, Manchester, Chemical Manufacturer.
1916. Hoskin, H. E., 35, Vallance Road, Alexandra Park, London, N., Works Manager and Chemist.
1916. Hoskins, Arthur A., Rainham, Kent, Explosives Chemist.
1890. Hoskins, A. Percy, "Clonlec," Rosetta Park, Belfast, Ireland, Analytical Chemist.
1899. Hoskins, Wm., 2009, Harris Trust Building, 111, West Monroe Street, Chicago, Ill., U.S.A., Chemist.
1914. Hough, Alex. T., 188, Boulevard de Charente, Paris XXc.
1917. Hough, Ralph, 2, Bridge Street, and Journals to "Newlands," Wilbraham Road, Alexandra Park, Manchester, Manufacturing Chemist.
1911. Hough, Samuel, Q10 West, Greta, Scotland, Analytical Chemist.
1899. Houlder, Bertram E., 50, Lady Margaret Road, Southall, Middlesex, Chemist.
1915. Houston, R. H., 46, Elm Park Road, London, S.W., General Manager (Aluminium Mills).
- O.M. Howard, A. G. Burnt House, Chigwell, Essex, Chemical Manufacturer.
1901. Howard, Bernard F., Firbank, Loughton, Essex, Chemist.
1887. Howard, D. Lloyd, Uphall Works, Ilford, Essex, Chemical Manufacturer.
1915. Howard, Dr. G. S., Lock Box 204, Carleton Place, Ontario, Canada, Research Chemist.
1898. Howard, Henry, 36, Amory Street, Brookline, Mass., U.S.A., Chemical Engineer.
1902. Howard, Nelson A., c/o General Chemical Co. of California, 705, Royal Insurance Building, San Francisco, Cal., U.S.A., General Manager.
1915. Howard, O. McG., Paint, Oil and Drug Review, 212, West Washington Street, Chicago, Ill., U.S.A., President and Journalist.
1913. Howard, Tom, 320, Wellington Road, Heaton Chapel, Stockport, Cheshire, Chemist.
1916. Howden, Robert, 12, Wolveleigh Terrace, Gosforth, near Newcastle-on-Tyne, Analytical Chemist.
1906. Howe, Chester A., 135, Oliver Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1916. Howe, Harrison E., 137, McGill Street, Montreal, Canada, Chemical Engineer.
1903. Howe, Jas. Lewis, Washington and Lee University, Lexington, Va., U.S.A., Professor of Chemistry.
1912. Howe, Dr. Percy R., 536, Pleasant Street, Belmont, Mass., U.S.A., Dentist.
1904. Howell, Walter L., Room 314, Custom House, New Orleans, La., U.S.A., Chemist.
1916. Howie, William, 4, Porter Street, Ibrox, Glasgow, Works Chemist.
1899. Howles, Fred., c/o McDougall Bros., 66-68, Port Street, Manchester, Chemist.
1889. Howorth, F. Wise, 10, New Court, Lincoln's Inn, W.C., Technical Chemist and Chartered Patent Agent.
1907. Howroyd, Richard R., c/o Calder Mersey Extract Co., Ltd., Ditton, near Widnes, Chemist.
1914. Howson, Herbert G., c/o Kynoch, Ltd., Umbogintwini, Natal, Analytical Chemist.
1906. Hoyler, Fritz, 93, Market Street, Perth Amboy, N.J., U.S.A., Chemist.
1896. Hoyte, Percy S., Gas Works, Coxside, Plymouth, Gas Engineer.
1916. Hubbard, R. S., Harrison Bros., and Co., Inc., 3500, Grays Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
1909. Hudson, Baker, Public Library, Middlesbrough, Librarian.
1899. Hudson, Dr. Edw. J., c/o Pioneer Iron Co., Marquette, Mich., U.S.A., Chemist.
1916. Hudson, G. Fred., Cawood Villa, Barnes Road, Castleford, Yorks, Works Manager.
1915. Hudson, G. Inglis, "Gudvangen," Arden Street, Coogee, Sydney, N.S.W., Australia, Manufacturing Chemist.
1914. Hudson, Norman S.W., No. 1, Staff House, Eastriggs, Dornock, Annan, Chemist.
1905. Hudson, O. F., Royal School of Mines, South Kensington, London, S.W., Lecturer on Metallurgy.
1900. Huebner, Julius, Linden, Cheadle Hulme, Cheshire, Director of Dyeing and Papermaking Departments (Municipal School of Technology).
1917. Huether, Davis J., c/o Dunlop Tyre and Rubber Goods Co., Booth Avenue, Toronto, Canada, Foreman.
1916. Huggins, A. F., "Cartref," Cromford Road, West Bridgford, Nottingham, Analytical Chemist.
- O.M. Hughes, J., 79, Mark Lane, London, E.C., Agricultural Chemist.
1917. Hulbert, Percy G., 3, Station Parade, Balham, S.W., Chemist.
1915. Hulme, Chas., Gas Works, Uxbridge, Middlesex, Gas Engineer.
1906. Hulme, Robert B., 1162, Union Avenue, Memphis, Tenn., U.S.A., Chemical Engineer and Manager.
1909. Hultman, G. H., St. Paulsgatan 31, Stockholm, Sweden, Chemical Engineer.
1905. Hulton, H. F. E., 15, Oak Hill Court, Putney S.W., Chemist.
1893. Humphrey, Chas., Homewood, Hartford, Cheshire, Alkali Works Manager.

1916. Humphrey, Wm. A., Seaton Lodge, Southbury Road, Enfield, Lead Products Works Manager.
1916. Humphrey, Edith E., 4, Cumberland Park, Acton, W., Works Chemist.
1902. Humphrey, Richard L., 1001, Harrison Building, Philadelphia, Pa., U.S.A., Civil Engineer.
1903. Humphreys, A. C., 165, Broadway, New York City, and (Jnls.) Stevens Inst. of Technology, Hoboken, N.J., U.S.A., Engineer.
1908. Humphries, Albert E., Coxes Lock Mill, Weybridge, Surrey, Flour Miller.
1912. Humphries, Herbert B. P., 14, Old Queen Street, Westminster, London, S.W., Consulting Chemist.
- O.M. Humphrys, N. H., 5, Wyndham Road, Salisbury, Wilts., Gas Engineer.
1900. Hunt, Arthur V., 5, The Wind, Lower Bebbington, Cheshire, Analytical Chemist.
- O.M. Hunt, Chas., 17, Victoria Street, Westminster, London, S.W., Civil Engineer.
1883. Hunt, J. S., Appleton, Widnes.
1903. Hunt, P. C. Holmes, 360, Collins Street, Melbourne, Vic., Australia, Gas Engineer.
- O.M. Hunt, W., Hampton House, Wood Green, Wodnesbury, Staffs., Chemical Manufacturer.
1893. Hunter, Prof. Matthew, Rangoon College, Rangoon, Burmah, Professor of Chemistry.
1902. Huntly, Geo. N., 14, Old Queen Street, Westminster, S.W., Analytical and Consulting Chemist.
1904. Hurren, F. H., c/o The Rover Co., Ltd., Coventry, Analytical Chemist.
1894. Hurry, E. H., Llanover, Churt, Farnham, Surrey, Mechanical Engineer.
1912. Hutchin, C. D., c/o Messrs. Meredith and Drew, Ltd., High Street, Shadwell, London, E., Biscuit Manufacturer.
1915. Hutchinson, Alfred, Manesty, Saltburn-by-the-Sea, General Manager, Skinningrove Iron Co.
- O.M. Hutchinson, T. J., Aden House, Manchester Road, Bury, Analytical and Consulting Chemist.
1909. Hutchison, Chas. F., Eastman Kodak Co., Kodak Park, Rochester, N.Y., U.S.A., Photographic Emulsion Maker.
- O.M. Huxley, Jas. H., c/o Vickers, Son, and Maxim, Ltd., River Don Works, Sheffield, Metallurgical Chemist.
1906. Huyett, Miles C., 1005, Morgan Building, Buffalo, N.Y., U.S.A., Mechanical Engineer.
1897. Hyams, Godfrey M., 312, Sears Building, Boston, Mass., U.S.A., Mines Manager.
1902. Hyde, Austin T., Box 98, Rumford Falls, Maine, U.S.A., Chemical Engineer.
1897. Hyde, B. T. Babbitt, 11, Broadway, New York City, U.S.A., Soap Manufacturer.
1899. Hyde, Fred. S., 215, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Research Chemist.
1899. Hyde, Wm. Grantley, Garden Wharf, Church Road, Battersea S.W., Assayer.
- I
1900. Ichioka, Dr. Tajiro, 19, Maruyama, Shinmachi, Hongo, Tokyo, Japan, Chemist (Imperial Japanese Navy).
1906. Iddings, Richard P., Arlington Mills, Lawrence, Mass., U.S.A., Chemist.
1885. Idris, T. H. W., 120, Pratt Street, Camden Town, N.W., Mineral Water Manufacturer.
1913. Illingworth, S. R., c/o Gas Lighting Improvement Co., Ltd., Pacific Wharf, West Ham, E., Works Chemist. On active service.
1909. Imison, C. S., The Cottage, Runcorn, Cheshire, Chemist, United Alkali Co.
1900. Imrie, John, 30, Osgathorpe Road, Sheffield, Producer Gas and By-Products Plant Manager.
1900. Ingalls, Walter R., "Engineering and Mining Journal," 10th Avenue at 36th Street, New York City, U.S.A., Mining Engineer and Metallurgist.
1889. Ingle, Dr. Harry, 26, Bond Street, Leeds, Organic Chemist.
1909. Ingleby, G. W., c/o John L. Seaton and Co., Ltd., Sculcoates, Hull, Director.
1916. Inglis, George P., 37, Stratford Road, West Bridgford, Nottingham, Works Chemist (Boots Pure Drug Co., Ltd.).
1906. Inglis, Dr. Jno. K. H., University of Otago, Dunedin, New Zealand, Professor of Chemistry.
1916. Inglis, Robert, c/o Lever Bros. (Japan), Ltd., P.O. Box, 174, Kobe, Japan, Chemist.
1912. Inglis, Robert J. C., "Rosedale," Airdrie, Lanarkshire, Analytical Chemist.
1911. Innes, Dr. Alfred G., H.M. Factory, Gretna, Technical Chemist.
1909. Innes, R. Faraday, c/o The British Chrome Tanning Co., St. Andrew's Tannery, Northampton, Chemist.
1903. Innes, Dr. Wm. Ross, 121, Norton Way, Letchworth, Herts, Chemist.
1910. Irvine, Prof. J. C., Chemical Research Laboratory, The University, St. Andrews, Scotland, Professor of Chemistry.
1884. Irving, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.
1911. Irwin, George C., c/o S. H. Johnson and Co., Ltd., Carpenter's Road, Stratford, E., Manager (Engineering Works).
- O.M. Irwin, W., Derwent Lodge, Cockermouth, Analytical Chemist.
1901. Isakovics, Alois von, Synflour Scientific Laboratories, Monticello, N.Y., U.S.A., Manufacturing Chemist.
1915. Isherwood, Dr. Percy C. C., c/o W. J. Bush & Co., Ltd., Hackney, N.E., and (Journals) Moss Cottage, Bushey Heath, Herts, Chief Chemist.
1900. Ittner, Dr. Martin H., c/o Colgate and Co., Jersey City, N.J., U.S.A., Soap and Essential Oil Chemist.
1912. Ivatt, Albert, The Engadine, Histon, Cambridge, Chemist (Foods).
- J
1890. Jackman, E. J., 60, Belgrave Road, Ilford, Essex, Technical Chemist.
1904. Jackson, Ernest W., Godrevy, Saltburn, Yorks, Analytical Chemist.
1991. Jackson, F., Smedley Bridge Works, Cheetham, near Manchester, Bleacher and Dyer.
1883. Jackson, Frederick, 44, Chapel Street, Salford, Manchester, Laboratory Furnisher.
1886. Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.
1901. Jackson, Percy G., c/o National Boiler and General Insurance Co., St. Mary's Parsonage, Manchester, Chemist.
1916. Jackson, R. S., c/o Kemp and Co., Ltd., Manufacturing Chemists, Bombay, India, Pharmacist and Analyst.
1890. Jackson, Saml., 3, Buckingham Gardens, Perambore Barracks, Madras, India, Analytical Chemist.
1902. Jackson, Samuel, c/o Wm. Metcalf, Ltd., Church, near Acerington, Director (Tar Distillery).
1898. Jackson, Thos., 31, Brownsville Road, Heaton Moor, near Stockport, Chemical Manufacturer.
1900. Jackson, Dr. W. Hatchett, Radcliffe Library, University Museum, Oxford, Librarian and Science Tutor (Keble College).
1899. Jackson, W. Morton, c/o British Oxygen Co., Ltd., Great Marlborough Street, Manchester, Manager.
- O.M. Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.
1915. Jacobs, Lionel L., Algoma Steel Corporation, Ltd., Sault Ste. Marie, Ontario, Canada, Superintendent Coke Plant.
1900. Jacoby, Arcll H., c/o National Aniline and Chemical Co., 100, William Street, New York City, U.S.A., Chemist.
1886. Jago, Wm., 17, Wilbury Avenue, Hove, Sussex, Barrister-at-Law.

1833. James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.
1916. James, Fredk. O., c/o Lever Bros., Ltd., H.C.B. Dept., Liver Buildings, Liverpool, Chemist.
1916. James, Geoffrey M., 515, Stewart Avenue, Ithaca, New York, U.S.A., Chemical Engineer.
1915. James, Hugh W., South Metropolitan Gas Co., Tar Works, Ordnance Wharf, East Greenwich, S.E., Technical Chemist.
1905. James, Oscar S., 6, Leuty Avenue, Toronto, Canada, Analytical Chemist.
1916. Jaques, Harry J., 11, Moreton Avenue, Stretford, Manchester, Chemist.
1914. Jaques, John, 66, Grove Road, Wanstead, N.E., Rubber Technologist.
1890. Jarman, Geo. S., Dalton Lodge, Huddersfield, Wool Extractor.
- O.M. Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.
1911. Jarrom, Harry G., 14, Goodwyn Avenue, Mill Hill, Middlesex, Managing Director (Gallenkamp and Co.).
1900. Jarvie, Jas., Ferndale, Kenmure Avenue, Bishopbriggs, Scotland, Chemist.
1914. Jaubert, Dr. G. F., 155, Boulevard Malesherbes, Paris, France, Technical Journalist.
1910. Jayne, David W., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U.S.A. Journals to c/o A. G. Peterkin, jun., The Barrett Co., Bridesburg Station, Philadelphia, Pa., U.S.A. Manager.
1913. Jeans, Harold, 165, Strand, London, W.C., Metallurgist.
1892. Jenkin, W. A., 12, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.
1905. Jenkins, Chas. D., 1384, Commonwealth Avenue, Allston, Mass., U.S.A., Chemist.
1894. Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.
1912. Jenkins, Leslie C. W., 26, Ulundi Road, Blackheath, S.E., Chemist (Wood Dyeing).
1912. Jenkins, Rees, 53, Shaftesbury Road, Ravenscourt Park, W., Analytical Chemist.
1916. Jenkinson, Stanley N., Edinburgh and Leith Flint Glass Co., Norton Park, Edinburgh, Glass Manufacturer.
1905. Jennison, Jas., Mount Nod, London Road, Greenhithe, Kent, Chemist.
1904. Jepson, John Elliott, c/o Star Paper Mill Co., Ltd., Feniscowles, near Blackburn, Chemist.
1899. Jerdan, Dr. David S., Temora, Colinton, Midlothian, Chemist (Gelatin Works).
1890. Jessop, Louis V., St. Bede's, Bushwood, Leytonstone, Essex, Chemist.
1904. Jewson, F. T., Earlith, near St. Ives, Hunts, Chemist.
1896. Job, Robt., 649, Roslyn Avenue, Westmount, Quebec, Canada, Analytical Chemist.
1886. Johnson, A. E., 24, Parkdale, Wolverhampton, Analytical Chemist.
1908. Johnson, Arthur, 7, Carlton Road, Bolton Road, Pendleton, Manchester, Chemist.
1904. Johnson, Cedric, Winnington Park, Northwich, Cheshire, Chemical Engineer.
1891. Johnson, Edmond E., c/o Adcocks, Drayton Park Works, Highbury, N., Chemical Engineer.
1904. Johnson, Dr. F. M. G., 286, Peel Street, Montreal, Canada, Chemist.
1904. Johnson, G. B., 7, Church Street, Liverpool, Wholesale Chemist.
1907. Johnson, H. Finnis, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., Sales Manager.
1900. Johnson, John, c/o John Johnson and Co., 37th Street and Second Avenue, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1913. Johnson, J. Carroll, on active service, Chemist.
- O.M. Johnson, J. E. J., 133, Earlham Grove, Forest Gate, E., Manufacturing Chemist.
1900. Johnson, John W. Haigh, West Riding Rivers Board, Wakefield, Yorks, Analytical Chemist.
1906. Johnson, Oliver L., c/o The Aspinook Co., Jewett City, Conn., U.S.A., Dye Works Manager.
1904. Johnson, S. Hearon, 7, Church Street, Liverpool Wholesale Chemist.
1916. Johnson, Walter L., c/o Bell Bros., Ltd., Middlesbrough, Iron Master.
1895. Johnston, Alex. R., 18, Percy Street, Ibrox, Glasgow, Analytical Chemist.
1906. Johnston, A. McA., Box 108, Germiston, Transvaal, Metallurgical Chemist.
1894. Johnston, G. Lawson. *See* Lawson-Johnston, G.
1904. Johnston, J. H., 8, Leopold Road, Wimbledon, S.W., Chemist and Bacteriologist.
1904. Johnston, Thos. J., 1, Brunswick Street, Edinburgh, Chemist.
1890. Johnston, Wm. A., The S. S. White Dental Manufacturing Co., Prince Bay, N.Y., U.S.A., Dental Enamel Manufacturer.
1894. Johnston, W. E. Lawson. *See* Lawson-Johnston, W. E.
1910. Johnstone, E. J., Park Place, Watertown, New York, U.S.A., Consulting Engineer and Industrial Chemist.
- O.M. Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.
1905. Johnstone, J. Swanston, Natal Distilleries Co., Bond Street, Durban, Natal, Distiller.
1903. Johnstone, S. J., "Rousdon," Clifford Road, New Barnet, Herts, Research Chemist.
1907. Jolliffe, Ernest H., Central Technical School, Toronto, Canada, Works Chemist.
1905. Jolliffe, Frank, 51, Vancouver Road, Forest Hill, S.E., Chemist.
1917. Jollyman, Frederic W., c/o The Imperial Tobacco Co., Ltd., Bodminster, Bristol, Analyst.
1904. Jones, Arthur B., 981, Central Avenue, Plainfield, N.J., U.S.A., Superintendent.
1913. Jones, B. Vaughan, P.O. Box 27 Petersburg, Va., U.S.A., Chemist and Manufacturer.
1912. Jones, Charles, Bearpark, Brancepeth Colliery, Durham, Coke Plant Manager.
1908. Jones, D. Trevor, 44, Ardrossan Road, Saltcoats, Ayrshire, Works Chemist.
1911. Jones, Edgar D., 157 Wakehurst Road, Clapham Common, S.W., Analytical Chemist.
1912. Jones, E. Gabriel, City Analyst's Laboratory, Ashton Street, Liverpool, Assistant Public Analyst for Liverpool.
1910. Jones, E. Protheroe, The Golden Horseshoe Estates Co., Salisbury House, London Wall, London, E.C., Secretary.
1902. Jones, E. Strangways, Sulphide Corporation, Ltd., Cockle Creek, N.S.W., Australia, Metallurgical Chemist.
1909. Jones, E. Willis, 22, Coleshill Terrace, Llanelli, South Wales, Chemical Manufacturer.
- O.M. Jones, E. W. T., 10, Victoria Street, Wolverhampton Analytical Chemist.
1897. Jones, Fred. W., 35, Addiscombe Road, Croydon, Technical Chemist.
1896. Jones, G. Cecil, 41, London Road, Forest Hill, S.E., Consulting Chemist.
1905. Jones, Harold, Villa Nova de Lima, Minas Geraes, Brazil, Analyst and Assayer.
1893. Jones, Herbert. *See* Sefton-Jones, H.
1910. Jones, Herbert J., 81, Ham Park Road, Stratford, E., Chemist.
1910. Jones, Ivor R., 54, Atlantic Chambers, Manchester, Chemical Merchant.
1905. Jones, J. E. Staey, Hearsall Works, Coventry, Consulting Chemist and Technical Metallurgist.
1904. Jones, J. Shirley, Moscow, Idaho, U.S.A., Chemist.
1894. Jones, M. W., Stonebeck, Brislington, Bristol, Manager (Oil and Colour Works).
1917. Jones, Richard O., 57, Browning Avenue, Rockferry, Cheshire, Research Chemist (Lever Bros., Ltd.).

- O.M. Jones, Walter Norris, Lancashire Metal Works, Widnes, Technical Chemist.
1915. Jones, W. B., 366, Washington Street, New York City, U.S.A., Research Chemist.
1903. Jones, Wm. App, c/o Boston Artificial Leather Co., 200, Fifth Avenue, New York City, U.S.A., Chemist.
1905. Jones, W. Ellis, 80, Arundel Avenue, Liverpool, Sugar Refiner.
1908. Joselin, Percy H., 81, Bennerley Road, New Wandsworth, S.W., Chemist.
1905. Joseph A. F., 296, Willesden Lane, N.W., Lecturer on Chemistry.
1900. Josephson, Edgar, c/o Pantasote Leather Co., Passaic, N.J., U.S.A.
1891. Joslin, Omar T., 3223, Spring Grove Avenue, Cincinnati, Ohio, U.S.A., Chemical Engineer.
1887. Jölet, Dr. C. H., 238, East 2nd Avenue, Roselle, N.J., U.S.A., Technical Chemist.
1904. Jowett, Dr. H. A. D., Phoenix Mills, Dartford, Kent, Research Chemist.
1903. Joyce, Clarence M., 145, Walnut Street, Leominster, Mass., U.S.A., Consulting Chemist (Nitro-cellulose).
1916. Joyce, Sydney R., c/o Curtis's and Harvey, Ltd., Cliff-at-Hoo, Kent, Analytical Chemist.
- O.M. Justice, Philip M., 55-56, Chancery Lane, London, W.C., Patent Agent.
- K
1896. Kalbfleisch, Franklin H., 31, Union Square West, New York City, U.S.A., Chemical Manufacturer.
1908. Kaliski, Dr. Maximilian S., 116, Broad Street, New York City, U.S.A., Technical Chemist.
1916. Katz, Israel, c/o Sulzberger and Sons Co., Union Stockyards, Chicago, Ill., U.S.A., Chief Chemist.
1901. Kauder, Dr. E. c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.
1892. Kaufmann, Dr. Herbert M., c/o Mutual Chemical Co., Jersey City, N.J., U.S.A., Chemist.
1904. Kaus, Dr. Emil, 96, High Street, Perth Amboy, N.J., U.S.A., Chemist.
1915. Kawakami Kaichi, c/o Sumitomo Electric Wire and Cable Works, Osaka, Japan, Chemical Engineer.
1885. Kawakita, Prof. Michitada, Imperial Engineering College, Tokio, Japan, Professor of Applied Chemistry.
1912. Kay, Jas. H., Fair Fields, Dundee Lane, Ramsbottom, Lancashire, Soap Manufacturer.
- O.M. Kay, Wm. E., 349, The Cliff, Broughton Park, Manchester, Printworks Chemist.
1910. Kaye, Henry R., c/o Cuming, Smith, and Co., Port Melbourne, Vic., Australia, Analytical Chemist.
1904. Kaye, Thos., 26, Rose Crescent, Perth, Scotland, Analytical Chemist.
1884. Keane, Dr. Charles A., Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., Principal.
- O.M. Kearns, H. W., Boothroyd, Brooklands, near Manchester, Dyer.
1897. Kearns, Jno. S., Cowpe Mills, Waterfoot, near Manchester, Chemist and Dyer.
1915. Keary, Harold E., The Glen, Stanford le Hope, Essex.
1908. Keen, Dr. Jas. L., 7, King Street, Chapside, London, E.C., Consulting Chemical Engineer.
1911. Keenan, Thomas J., 117, East 24th Street, New York City, U.S.A., Paper Chemist.
1915. Keetland, C. G., c/o The Standard Chemical Iron and Lumber Co., 524, St. Ambrose Street, Montreal, Canada, Montreal Manager.
1908. Keith, Jas. W., c/o Parry and Co., Ranipettai, North Arcot Dt., Madras Presidency, India, Analytical Chemist.
1915. Keller, D. Rayment, 20, Carey Place, Watford, Herts, Works Chemist.
1907. Keller, Dr. Edward, 365, W. 56th Street, New York City, U.S.A., Chemist and Metallurgist.
1905. Keller, Robt. J., 89, Barclay Street, New York City, U.S.A., Dyestuff and Chemical Merchant.
1885. Kellner, Dr. Wm., 135, Victoria Road, Old Charlton, S.E., Chemist to War Department.
1908. Kellogg, H. W., c/o National Electrolytic Co., Niagara Falls, N.Y., U.S.A., General Manager.
1916. Kelly, Wm., c/o Canadian Explosives Ltd., Room 807, Transportation Building, Montreal, Canada, President's Assistant.
1916. Kempson, J. F., Crow Lees, Thorpe Road, Norwich, Chemical Manufacturer.
1907. Kendall, G. F., Chemical Works, Stratford-on-Avon, Chemical Manufacturer.
1912. Kennedy, Carl D., c/o General Rubber Co., Kisaran Asahan, Sumatra, D.E.I., Chemist.
1916. Kennedy, J. R., 21, Crown Park Road, Toronto, Canada, Perfumer.
1916. Kenner, Capt. James, A.P.O. 4 (Shops), B.E.F., Chemist.
1912. Kent, Raymond W., East Palistine, Ohio, U.S.A., Chemist.
1914. Kenyon, James, U.K. Chemical Products, Ltd., Sutton Oak Works, St. Helens, Analytical Chemist.
1903. Kenyon, Percy S., Park House, Cheadle Hulme, Cheshire, Drysalter.
1889. Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.
1915. Kerfoot, Thos., Pole Bank Hall, Gee Cross, Cheshire, Manufacturing Chemist.
1899. Kern, Walter P., c/o General Chemical Co., 1642, Halle Street, Laurel Hill, Boro' of Queens, N.Y., U.S.A., Chemist.
1916. Kernick, Fred S., c/o Kernick and Sons, Ltd., Old Rink Building, Moira Terrace, Cardiff (Journals to 192, Newport Road, Cardiff), Laboratory Manager.
1915. Kernot, Dr. J. C., Furze Hill, Augustus Road, Wimbledon Park, S.W., Doctor of Chemistry.
1906. Kerr, Charles H., c/o American Optical Co., Southbridge, Mass., U.S.A., Director of Research Laboratory.
1912. Kerr, R. Vaughan, Saboaria Seixas Irmaos y Ca., Parahyba, Brazil, Technical Chemist.
1890. Kerr, Saml. T., 516, North Delaware Avenue, Philadelphia, Pa., U.S.A., Salt Manufacturer.
1897. Kerr, Wm. M., 1421, Chestnut Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1896. Kershaw, Jno. B. C., 9, Grosvenor Road, Colwyn Bay, N. Wales, Analytical Chemist.
1915. Kertland, Chas. G., The Standard Chemical and Lumber Co., 524, St. Ambrose Street, Montreal, Canada, Local Manager.
1903. Kesava-Menon, A., Government Soap Works, Calicut, Madras, India, Chemist.
1902. Kessler, Henry W., 1640, East 115th Street, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
1893. Kestner, Paul, 16, Rue de Chabrol, Paris, France, Chemist.
1900. Kewley, Jas., The Refinery, Portishead, near Bristol, Oil Refinery Manager.
1890. Keys, W. H., Hall End Works, West Bromwich, Oil and Chemical Manufacturer.
1900. Kilgore, Berj. W., North Carolina Dept. of Agriculture, Raleigh, N.C., U.S.A., Chemist.
1901. Kilmer, Fred. B., c/o Messrs. Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemical Manufacturer.
- O.M. Kitch, Prof. E., Komaba, Haslemere, Surrey, Professor of Chemistry.
- O.M. King, A. J., Elleray, Windermere, Bleacher and Finisher.
1917. King, Albert P., 98, Foxley Road, Purley, Chemical Manufacturer.
1907. King, C. A., c/o The Farnley Iron Co., Farnley, near Leeds, Technical Chemist.
1913. King, Edward W., New Liverpool Rubber Works, Walton, Liverpool, Analytical Chemist.
1915. King, George, 25, Whitmore Road, Small Heath, Birmingham, Research Chemist.

1911. King, Harold, Welcme Research Laboratories, King Street, Snow Hill, E.C., Chemist.
- O.M. King, J. Falconer, 43, Stirling Road, Edinburgh, Consulting Chemist.
1910. King, John, Summerville Gardens, Latchford, Warrington, Lancashire, Works Manager.
1913. King, Dr. Robert C., Aptekarsky Prospect Sa, Petrograd, Russia, Chemist.
1895. King, Sidney J., "Blenheim," Union Road, Surrey Hills, Melbourne, Victoria, Australia, Analytical Chemist.
- O.M. King, Walter R., "Torville," The Cliffs, Southend-on-Sea, Chemical Manufacturer.
1905. King, Warren C., 72, Front Street, New York City U.S.A., President, Independent Chemical Co.
1916. King, Wm. E., 24, Tantallon Road, Balham, S.W., Research Chemist.
1917. King, William W., "Double Trees," The Ridgway, Sutton, Surrey, Chemical Manufacturer.
1896. Kingdon, G. Holman, c/o Joseph Crosfield and Sons, Ltd., Warrington, Technical Chemist.
1908. Kingsbury, Percy C., German-American Stoneware Works, 50, Church Street, New York City, U.S.A., Chief Engineer.
1883. Kingsford, T. P., Oswego, N.Y., U.S.A., Starch Manufacturer.
- O.M. Kingzett, C. T., "Maplin," Frinton on Sea, Essex, and (Journals) Sanitas Co. Ltd., Locksley Street, Limehouse, E., Chemical Manufacturer.
1906. Kinnersley, H. W., "Ingleside," Abbey Park, Keynsham, Somerset, Chemist and Manufacturer.
1897. Kipping, Dr. F. Stanley, F.R.S., University College, Nottingham, Prof. of Chemistry.
1914. Kirby, William, 50, Mayhill Road, Charlton, Kent, Chemist.
1916. Kirkcaldie, J. C., The Laboratory, Bo'ness Distillery, Bo'ness, Scotland, Analytical and Consulting Chemist.
1908. Kirkhope, T. Bertram, Sandbank, Gwithian, Hayle, Cornwall, Explosives Works Chemist.
1905. Kirkland, John, 2, Cranworth Gardens, Brixton Road, S.W., Technical Instructor.
1900. Kirkpatrick, Prof. S. F., Kensington Avenue, Kingston, Ont., Canada, Professor of Metallurgy.
1913. Kirsebom, Gustave, Readingsgade 11, Christiania, Norway, Metallurgical Engineer.
1911. Kiretein, H. C. See Bingham, H. C.
1902. Kitchen, Wm. J., Port Melbourne North, Vic., Australia, Soap and Candle Manufacturer.
1883. Kitto, B., 26, Lancaster Road, Finsbury Park, London, N., Analytical Chemist.
1900. Kittredge, H. G., c/o The Kay and Ess Co., Dayton, Ohio, U.S.A., Chemist.
1908. Klaber, Wm., c/o Castle Kid Co., Camden, N.J., U.S.A., Chemist.
1900. Kleber, Dr. Clemens, Clifton Chemical Laboratory, Passaic, N.J., U.S.A., Director.
1911. Klein, C. A., Brimsdown Avenue, Enfield Highway, Middlesex, Works Chemist.
1909. Klemm, W. F. E., 58 Woodlands Road, Aigburth, Liverpool, Chemist.
1908. Klien, Dr. J. L. See Keen, Dr. J. L.
1903. Kline, Clarence M., 429, Arch Street, Philadelphia, Pa., U.S.A., Wholesale Druggist.
1889. Klipstein, A., Messrs. A. Klipstein and Co., 644-654, Greenwich Street, New York City, U.S.A., Chemical Manufacturer.
1902. Klipstein, Ernest C., 93, Prospect Street, East Orange, N.J., U.S.A., Chemical Merchant.
1916. Klotz, J. R. N., c/o The Newport Hydro Carbon Co., 32, Liberty Street, New York City, U.S.A., Chemist.
1913. Klotz, W. C., Canadian Ammonia Co., Ltd., Toronto, Canada, Chemist.
1891. Knaggs, Alfred B., c/o Dr. Knaggs, Oak House, New North Road, Huddersfield, Technical Chemist in Dyeworks. Retain Journals.
1911. Knapp, Arthur W., c/o Cadbury Bros., Ltd., Bourneville, near Birmingham, Research Chemist.
1911. Knapp, Harry P., c/o Talbot Dyewood and Chemical Co., 38-44, Middle Street, Lowell, Mass., U.S.A., Chemical Manufacturer.
1916. Knapp, Lionel F., Hertcombe, Kingston Hill, Surrey, Chemist.
1892. Knecht, Dr. E., Beech Mount, Marple, Cheshire, Professor of Tinctorial Chemistry.
1904. Kniffen, Frederick, Holly Oak, Del., U.S.A., Chemist.
1887. Knight, A. H., 51, Highfield Street, Liverpool, Assayer.
1903. Knight, Harley F., 14, Old Queen Street, Westminster, S.W., Analyst.
1887. Knights, J. West, 67, Tenison Road, Cambridge, Analytical Chemist.
1885. Knipier, F., "Strathberg," Greensborough, near Melbourne, Victoria, Starch Manufacturer.
1907. Knoedler, E. L., c/o Welsbach Co., Gloucester City, N.J., U.S.A., Factory Foreman.
1910. Knott, E. Anthony F., The Priestman Collieries, Ltd., Ottovale Coke Works, Blaydon-on-Tyne, Works Chemist.
1904. Knowles, W. R., The Hollies, Wood Green, Wednesbury, Chemical Works Manager.
1886. Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; Sugar Manufacturer and Refiner.
1906. Knudsen, Kristian H., 96, Maiden Lane, New York City, U.S.A., Chemist.
1904. Koch, J. A., Bluff and Pride Streets, Pittsburg, Pa., U.S.A., Chemist.
1911. Kochs, A. Victor. See Derry, A. V.
1904. Koebig, Dr. J., 934, Union Oil Building, Los Angeles, Cal., U.S.A., Consulting Chemical Engineer.
1909. Kockkoek, Lt. P. R., No. 2, Special Co., R.E., B.E.F., France. Retain Journals.
1915. Koenig, W. A., 1802, North Smallwood Street, Baltimore, Md., U.S.A., Chemist.
1916. Koetz, Metty, c/o L. Borne, Limoilon, Canada, Chemist.
1884. Kohn, Dr. Charles A. See Keane, Dr. Charles A.
1902. Kohnstamm, Lothar S., 87, Park Place, New York City, U.S.A., Chemist.
1915. Kondakow, Prof. I., Prudowaja, 74, Jurjew, Livland, Russia, Director of Pharmaceutical Institute.
1913. Kondo, K., 136, Yoyogi, Tokyo, Japan, Chemical Engineer.
1894. Krause, Dr. Albert H., 1444, West 98th Street, Cleveland, Ohio, U.S.A., Chemist (Grasselli) Chemical Co.).
1898. Krebs, H. J., 806, Franklin Street, Wilmington, Del., U.S.A., Manufacturing Chemist.
1915. Kübler, Ernest, c/o The West Indies Chemical Works, Ltd., 1, Brazennose Street, Manchester, Dyeworks Chemist.
1916. Krobot, S., 220, Broadway, New York City, U.S.A., Chemical Engineer.
1917. Kulp, Samuel R., 414, N. 5th Street Allentown, Pa., U.S.A., Chemist.
1904. Kunz, Dr. George F., c/o Tiffany and Co., 409, 5th Avenue, New York City, U.S.A., Gem Expert.
1905. Kurt, Franklin T., 553, Boylston Street, Boston, Mass., U.S.A., Professor of Chemistry, B.Y.M.C.A.
1916. Kutsuki, Viscount Tsumasada, Kwayaku-Kenkusho, Itabashi, Tokyo, Japan, Lt. Col.
1900. Kuttroff, Fred., 128, Duane Street, New York City, U.S.A., Merchant.
- O.M. Kynaston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.

L

1906. Lacell, Harold G., Liderley, Lansdowne Road, Finchley, N., Chemist.
1890. Lacey, E. C., St. Julian's Lodge, St. Julian's Farm Road, West Norwood, Manufacturing Chemist.
1903. Lachman, Dr. Arthur, Corner The Alameda and Newhall Street, San Jose, Cal., U.S.A., Chemical Engineer.
115. Lacy, Edwin, c/o Harland and Wolff, Ltd., Queen's Island, Belfast, Engineering Works Chemist.

1913. Laib, Walter, Rittman, Wayne Co., Ohio, U.S.A., Chemist (Ohio Salt Co.).
- O.M. Lake, G., jun., Lee Mount, Glossop, Derbyshire, Analytical Chemist.
1907. Lake, Henry B., The Manbré Saccharine Co., Fulham Palace Road, Hammersmith, W., Manager.
1900. Lamar, Wm. R., 8502, Ferriss Street, Woodhaven, New York City, U.S.A., Chemical Manufacturer.
1898. Lamb, Morris Chas., Leathersellers' Technical College, 176, Tower Bridge Road, London, S.E., Chemist.
1912. Lancaster, Harry C., 39, Ladbroke Grove, Kensington, W., Managing Director.
1907. Lancaster, Harry M., Laboratory, Provincial Board of Health, 5, Queen's Park, Toronto, Canada, Chemist.
1916. Land, Henry S., c/o Hardman and Holden, Ltd., Tar Distillers, Manchester: (J.) 7, Amos Street, Church Lane, Moston, Manchester, Works Chemist.
1914. Lander, Dr. G. D., Royal Veterinary College, Camden Town, London, N.W., Consulting Chemist.
1910. Landrum, R. D., c/o The Harshaw, Fuller and Goodwin Co., Electric Building, Cleveland, Ohio, U.S.A., Chemical Engineer.
1910. Lane, J. Henry, 3, Arbour Square, Stepney, London, E., Analytical and Consulting Chemist.
1903. Lane, Nathaniel J., U.S. Laboratory, 641, Washington Street, New York City, U.S.A., Chemist.
1915. Lane-Hall, 2nd Lieut. R., 4, Lloyds Avenue, London, E.C. (Journals to 2nd Northamptonshire Regt., R.E.F., France), Chemical Merchant.
1893. Lang, Dr. Wm. R., University of Toronto, Canada, Professor of Chemistry.
1892. Langer, Dr. Carl, Bucklebury Place, Woolhampton, Berks, Analytical Chemist.
1914. Langlands, S. H. B., Glasgow Corporation Lighting Dept., 20, Trongate, Glasgow, Chief Inspector of Lighting.
1897. Langmuir, Arthur C., c/o Marx and Rawolle, 9, Van Brunt Street, Brooklyn, N.Y., U.S.A., Factory Manager.
1902. Langmuir, F. Leighton, 288, Bloor Street West, Toronto, Canada, Chemist.
1898. Langstaff, Wm., 35, Orchard Street, Elizabeth, N.J., U.S.A., Chemist.
1915. Langton, H. M., The Universal Oil Co., Ltd., Kynochtown, Stanford-le-Hope, Essex, Research Chemist.
1916. Lankshear, F. R., 63, Birchfield Road, Rusholme, Manchester, Works Manager.
1900. Lant, Herbert, "Ivy Bank," Wath-on-Dearne, near Rotherham, Yorks, Chemist and Manager.
1909. Lantsberry, Fred. C. A. H., Birmingham Small Arms Co., and (Journals) 63, Walford Road, Sparkbrook, Birmingham, Metallurgical Chemist.
1906. Lantz, Lieut. Alfred, 139, Rue La Fayette, Paris, France, Chemical and Colour Manufacturer.
1914. Laplante-Courville, H., 399, Viger Avenue, Montreal, Canada, Lecturer.
1915. Lapworth, Prof. Arthur, F.R.S., The University, Manchester, Professor of Organic Chemistry.
1903. Larter, Alfred T., 5, Rookfield Avenue, Muswell Hill, N., Chemist.
1904. Lasher, F. G., 104, Grove Street, Brooklyn, N.Y., U.S.A., Chemist.
1884. Latham, Baldwin, Parliament Mansions, Victoria Street, Westminster, S.W., Civil Engineer.
1889. Latham, J. J., Mill House, Bold, Widnes, Chemical Works Manager.
1907. Lathwood, Arthur, c/o Borax Consolidated, Ltd., 16, Eastecheap, London, E.C., and (Jnls.) The Briars, Maidstone Road, Bounds Green, N., Chemist.
1914. Lander, Dr. Alex., College of Agriculture, 13, George Square, Edinburgh, Lecturer in Chemistry.
1914. Laurie, Dr. A. P., Heriot Watt College, Chambers Street, Edinburgh, Principal.
1909. Law, (Lt.) Douglas J., Trent Bridge Leather Works, Nottingham, Chemist.
1915. Law, Dr. H. Drake, Castle Fields, Rastrick, Brighouse, Yorks, Chemist.
1913. Law, John A., c/o Barry, Ostlere, and Shepherd, Ltd., Forth Works, Kirkcaldy, Scotland, Lino-leum Works Director.
- O.M. Lawrence, Jas., c/o Arch. Hamilton, 70, Glassford Street, Glasgow, Explosives Manufacturer.
1916. Lawrence, Jas. C., 16, Glencairn Drive, Pollok-shields, Glasgow, Chemical Plant Manufacturers.
1911. Lawrence, Wm. A., Manorville, Long Island, N.Y., U.S.A., Director.
1916. Lawrenson, Thos., Plas Newydd, Croxton Lane, Middlewich, Cheshire, Manufacturing Chemist.
1916. Lawson, John, 49, Melton Road, West Bridgford Notts, Pharmaceutical Chemist.
1904. Lawson, Jos. H. S., Rodney Street Works, Oldham Road, Manchester, Salesman.
1891. Lawson-Johnston, G., (Journals) 29, Portman Square, W., and 152, Old Street, E.C., Vice-Chairman of Bovril, Ltd.
1894. Lawson-Johnston, W. E., c/o Bovril, Ltd., 152, Old Street, London, E.C., Director.
1916. Layton, W. T., 313, Friern Road, Dulwich, S.E., Editor, South Met. Gas Co.'s Journal.
1907. Leach, Dr. F. P., "Lynden," Frodsham, Cheshire, Research Chemist.
1908. Leake, Percy C., Prospect House, Ferryhill Village, co. Durham, Tar Works Manager.
1898. Lean, Geo., 3, Park Quadrant, Glasgow, Chemist.
- O.M. Leather, Major J. Walter, 3rd Garrison Batta., Cheshire Regt., Ramsey, Isle of Man, Retain Journals, Government Chemist.
1893. Le Boutilier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.
1904. Le Chatelier, Prof. H., 75, Rue Notre Dame des Champs, Paris, France, Professor (l'Ecole des Mines).
1896. Leecombe, W. G., Cambridge Works, Knott Mill, Manchester, Engineer.
1896. Lederle, Dr. E. J., Stamford, Conn., U.S.A., Chemist.
1892. Ledoff, Prof. A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.
1895. Ledoux, Dr. Albert R., 99, John Street, New York City, U.S.A., Chemist.
1903. Ledoux, Aug. D., 15, William Street, New York City, U.S.A., Importer of Pyrites.
1915. Ledoux, P., Société Minière Métallurgique de Peniarroya, 12, Place Vendôme, Paris, Director-General.
1915. Ledwidge, Jos. G., Municipal Technical School, Drogheda, Ireland, Analytical Chemist.
1905. Lee, Ashton, Lawrence, Mass., U.S.A., Manufacturing Chemist.
1905. Lee, Frank W., Lawrence, Mass., U.S.A., Manufacturing Chemist.
1905. Lee, John C., Wellesley, Mass., U.S.A., Assistant Engineer (American Telegraph and Telephone Co.).
1898. Lee, Jno. L., Woodfield, Lytham, Lancashire, Dyer and Bleacher.
1885. Lee, S. Wright, 6-10, Whitechapel, Liverpool, Wholesale Druggist.
1906. Lee, William, 28, Sherard Gardens, Eltham, Kent, Works Chemist.
1915. Leech, Ben., 77, Pownall Street, Macclesfield, Consulting Chemist.
1916. Leech, Herbert L., Craig Royston, Gonrock Road, Eltham, Kent, Director and Works Manager.
1912. Lees, Arnold, West View, Town Street, Beeston, Leeds, Analytical Chemist.
1915. Leese, Ernest, c/o Wilson's Portland Cement Co., Ltd., Warkworth, Auckland, New Zealand, Works Chemist.
1914. Legg, Bertram, Minas de Rio Tinto, Prov. Huelva, Spain, Chemist and Assayer.
1915. Leggett, T. S. L., 35, Sufton Street, Birkby, Huddersfield, Chemist.

1907. Lehmann, Dr. Adolf L. F. University of Alberta, Strathcona, Alberta, Canada, Professor of Chemistry.
1888. Leigh, Cecil, Birmingham Metal and Munition Co., Adderley Park Rolling Mills, Birmingham, Technical Chemist.
1902. Leighton, A. E., Commonwealth Cordite Factory, Maribyrnong, Victoria, Australia, Analytical Chemist.
1916. Leighton, E. W., "Karachi," Empress Avenue, Woodford Green, Essex, Metallurgist.
1894. Leitch, Jno. W., Milnsbridge Chemical Works, near Huddersfield, Aniline Dye Manufacturer.
1904. Le Maistre, Fred. J., Ridley Park, Pa., U.S.A., Research Chemist.
1898. Leman, Wm. T., P.O. Box 747, Chicago, Ill., U.S.A., Oil and Asphalt Agent.
1883. Lennard, F., c/o Forbes, Abbott, and Lennard, Ltd., Chemical Works, Shorham, Sussex, Chemical Manufacturer.
1917. Lentz, C. E., 1235 Lincolnway W., South Bend, Indiana, U.S.A., Glue Engineer.
1884. Leonard, Wm. J., 1, Lindfield Gardens, Hampstead, N.W., Naphtha Distiller.
1904. Lesley, R. W., 604, Pennsylvania Building, Philadelphia, Pa., U.S.A., Cement Manufacturer.
1917. Leslie, Eugene H., Research Lab., General Petroleum Corporation, 3800, Santa Fe Avenue, Los Angeles, Cal., U.S.A., Chief Chemist.
1907. Leslie, Dr. Fred. A., 79, Post Avenue, New York City, U.S.A., Chemist.
1904. Lessing, Dr. Rudolf, Southampton House, 317, High Holborn, London, W.C., Consulting Chemist.
1912. Lessner, C., Carril, Spain, Metallurgical Chemist.
1892. Lester, J. H., The Laboratory, 56, Oxford Street, Manchester, Analytical Chemist.
1899. Le Sneur, Major Henry R., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Lecturer.
1909. Lever, W. Hulme, Heathfield, Bebington, Cheshire, Soap Manufacturer.
1891. Leverhulme, Rt. Hon. Lord, Thornton House, Thornton Hough, Cheshire, Soap Manufacturer.
1901. Levett, Walter, Holmdands, Stanford-le-Hope; and (Journals) Mines Safety Explosives Co., Stanford-le-Hope, Essex, Factory Manager.
1915. Levey, Alfred E., 18, Roxburgh Avenue, Higher Trannura, Cheshire, Works Chemist.
1903. Levi, Dr. Louis E., 781, Sherman Boulevard, Milwaukee, Wis., U.S.A., Chemist.
1912. Levin, Isaac H., P.O. Box 562, Dayton, Ohio, U.S.A., Chemist.
1906. Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.
1901. Levinstein, Dr. Herbert, c/o Levinstein, Ltd., Blackley, near Manchester, Chemist.
1917. Levy, Frank, No. 3 Staff Hostel, Eastgriggs, Annan, Dumfries, Chemical Engineer.
1909. Levy, Louis S., 80, Maiden Lane, New York City, U.S.A., Editor "American Perfumer."
1916. Levy, Stanley I., 9, Parkhurst Road, Holloway, N., Chemist.
1901. Levy-Mond, Dr. Albert. See Mond, Dr. Albert L.
1898. Lewin, H. James, Royal Clarence Yard, Gosport, Hants, Analytical Chemist.
1914. Lewis, C. Preston, 223, Brixton Hill, London, S.W., Technical Chemist.
1896. Lewis, Daniel C., c/o Millville Manufacturing Co., Millville, N.J., U.S.A., Dye Works Chemist.
1904. Lewis, Edw. W., c/o J. G. Ingram and Sons, London India Rubber Works, Hackney Wick, N.E., Chemist.
1909. Lewis, Reginald J., Govt. Explosives Office, 423, Flinders Lane, Melbourne, Australia, Chemist.
1900. Lewis, Dr. S. Judd, The Laboratories, Staple Inn Buildings, High Holborn, London, W.C., Analytical Chemist.
1914. Lewis, Prof. W. C. McC., Muspratt Laboratory, The University, Liverpool, Professor of Physical Chemistry.
1913. Lewkowitsch, Mrs. K. J., The Lewkowitsch Laboratories, 71, Priory Road, West Hampstead, N.W.
1907. Leyson, Lewis T., Penseynor, near Neath, S. Wales, Analytical Chemist.
1916. Licence, A. B. C., 150, Springbank Road, Hither Green, S.E., Director and Chemist (Dye Manufacturing Co.).
1901. Lichtenstein, Alf. F., c/o Geisenheimer and Co., P.O. Box 994, New York City, U.S.A., Chemist.
1913. Lichtenstein, L. M., Royal Albert and Victoria Docks Chemical Works, Silvertown, London, E., Manufacturing Chemist.
1917. Lidstone, Frank M., 37, Powell Street, Derby, Analytical Chemist.
1916. Liebert, Dr. Martin, c/o Spencer Chapman and Messel, Ltd., 36, Mark Lane, E.C., Chemical Manufacturer.
- O.M. Liebmann, Dr. A., The Whim, Weybridge, Surrey, Consulting Chemist.
- O.M. Lightfoot, T. E., Fernleigh, Accrington, Calico Printer's Chemist.
1905. Liley, Thos. A., 46, Westover Road, Bramley, Leeds, Chemist.
1898. Lilly, Josiah K., c/o Eli Lilly and Co., Indianapolis, Ind., U.S.A., Manufacturing Pharmacist.
1904. Lindemann, Ottocar, 53, Victoria Street, Westminster, S.W., Managing Director (Korting Bros., Ltd.).
1908. Lindfield, James H., c/o Messrs. Martineau, King Edward Street, Whitechapel, E., Technical Chemist.
1897. Lindsay, Robt., Transvaal G.M. Estates, Ltd., Pilgrim's Rest, Lydenburg, Transvaal, Chemist.
1911. Line, Chas. A., 39, Beaufort Road, Edgbaston, Birmingham, Technologist.
1890. Ling, Arthur R., Laboratory, 74, Great Tower Street, London, E.C., Consulting Chemist.
1896. Lishman, Geo. P., Lambton Coke Works, Fence Houses, Co. Durham, Colliery Chemist.
1905. Little, Arthur D., 93, Broad Street, Boston, Mass., U.S.A., Consulting Chemist.
1916. Littler, Robert P., United Alkali Co., Ltd., Netham, Works, Bristol, Chemist.
- O.M. Littlejohn, Jas., c/o Littlejohn and Whitby, P.O. Box 849, Johannesburg, Transvaal, Analytical Chemist.
1916. Littlewood, Ernest A., 6, Monart Road, Blackley, Manchester, Works Chemist.
1904. Livermore, W. D., Washington Mill, Lawrence Mass., U.S.A., Chemist.
1886. Liversedge, A. J., 63, Northampton Road, Croydon, Mechanical Engineer.
1914. Liversedge, John A., The Whangarei Freezing Works, Restah, New Zealand, Assistant Lead Mill Manager.
- O.M. Liversedge, Prof. A., F.R.S., Field Head, Coombe Warren, Kingston, Surrey, Professor of Chemistry.
1883. Livingston, W. J., 30, Fountayne Road, Stoke Newington Common, London, N., Analytical Chemist.
1903. Llewellyn, Ivor P., 149, Moorland Road, Stockport, Chemist.
1907. Llewellyn, W. B., Park House, Westbourne Park, Urmoston, nr. Manchester, Chemist.
1909. Lloyd, Edward, "Kings Pylon," Cavendish Road, Bowdon, Cheshire, Chemical Engineer.
1904. Lloyd, Leonard B., Whitehall Street, Yarraville, Victoria, Australia, Cannier.
1907. Lloyd, Dr. Lorenzo L., Technical College, Bradford, Yorks, Lecturer in Chemistry.
1916. Lloyd, Prof. Stewart J., University, Alabama, U.S.A., Professor of Chemistry.
1900. Lloyd, Thos. H., 7, Beacon Hill Road, Newark-on-Trent, Analyst.
1916. Lloyd-Wilky, W. S., Invicta Mills, Pew Common Lane, London, E., Charcoal Manufacturer.

1914. Lockett, William T., School of Technology, Manchester, Research Chemist.
1915. Lockie, J. R., Ascog, Meikleriggs, Paisley, Scotland, Analytical Chemist.
1916. Lockwood, Jos. H., 3, Ridge Road, Winchmore Hill, London, N., Analytical Chemist.
1888. Lodge, Edw., 35, Scale Hill, Cowcliffe, Huddersfield, Chemist and Dyer.
1917. Lodge, George, Levinstein Ltd., Blackley, Manchester, Research Chemist.
1916. Lodge, Wm. C., c/o Canadian Inspection Co., 603, Canadian Express Building, Montreal, Canada, Chemist.
1907. Lomax, E. Lawson, c/o Anglo-Persian Oil Co., Ltd., Gresham House, 24 Old Broad Street, London, E.C., Chemist.
1901. Long, Eugene J., c/o E. O'Callaghan and Son, City Tannery, Limerick, Ireland, Tanner.
1909. Long, George M., Cudahy, Wis., U.S.A., Glue Maker.
1898. Longstaff, Dr. J. P., Broadway Chambers, Westminster, London, S.W., Journals to "Arcadia," Squirrels Heath, Romford, General Secretary.
1890. Lord, F. J., Winmarleigh, Southbourne, Bournemouth, Hants, Analytical Chemist.
1896. Lord, Jno. Lloyd, Wellington Cement Works, Elton, Bury, Lancs, Chemist and Manager.
- O.M. Lorenz, H., 7 and 8, Idol Lane, London, E.C., Chemical Merchant.
1917. Lorimer, John W., c/o Curtis's and Harvey, Dartford, Kent, Analytical Chemist.
1905. Loring, Lindsley, 40, Central Street, Boston, Mass., U.S.A., Vice-President (Cochrane Chemical Co.).
1909. Lorieberg, C., c/o R. W. Greeff and Co., Thames House, Queen Street Place, London, E.C., Chemical Merchant.
1916. Lothbury, Philip A., 3a, Kingdon Road, West Hampstead, London, N.W., Managing Director, Dye Manufacturing Co.
- O.M. Lott, F. E., The Laboratory, Bridge Chambers, Burton-on-Trent, Consulting Brewing Chemist.
1894. Louis, Prof. Henry, Armstrong College, Newcastle-on-Tyne, Professor of Mining.
- O.M. Love, Dr. E. G., 124, East 15th Street, New York City, U.S.A., Analytical Chemist.
- O.M. Lovibond, T. W., West Jesmond House, Newcastle-on-Tyne, Brewer.
1913. Low, Frank S., 52, N. Pearl Street, Buffalo, New York, U.S.A., Chemical Engineer.
1900. Low, Prof. Wilson H., Cudahy Packing Co., South Omaha, Neb., U.S.A., Chemist.
1911. Lowcock, J. Harold, 39, Wickham Way, Park Langley, Beckenham, Kent, Chemist.
1913. Lowe, Austin, 39, Chelverton Road, Putney, S.W., Research Chemist.
1887. Lowe, Clement W., Thorneyholme, Knutsford, Cheshire, Manufacturing Chemist.
- O.M. Lowe, W. F., 18, Hough Green, Chester, Analytical Chemist.
1906. Lawson, Wm., The University, Leeds, Chemical Lecturer.
1917. Loynes, Walter C., 308, Dudley Road, Birmingham, Analytical Chemist and Assayer.
1895. Lucas, Ah., Laborstories, Public Works Ministry Gardens, Cairo, Egypt, Analyst.
1892. Lucas, Bernard R., Winnington Park, Northwich, Cheshire, Alkali Works Manager.
- O.M. Luek, A. Courtenay, San Martin 475, Buenos Aires, Argentina, Explosives Chemist.
1913. Luey, Arthur J., c/o Turner & Co., 6, Dale Street, Liverpool, Consulting Engineer.
1916. Luff, B. D. W., 85, Ashley Terrace, Edinburgh Technical Chemist.
1915. Lumley, Edgar P., 37, General Graham Street, Chester Road, Sunderland, Chemist.
1900. Lummus, Walter E., 39, Bassett Street, Lynn, Mass., U.S.A., Manager.
1903. Lumsden, Alex. A., Forth Chemical Works, Bo'ness, Scotland, Technical Chemist.
1910. Lumsden, William W., 39, Caledonia Road, Saltcoats, Scotland.
1888. Lund, Jas., 142, Hawthorne Street, Malden, Mass., U.S.A., Ammonia Works Manager.
1915. Lund, W. Jackson, "Penryn," Temple Road, Stowmarket, Suffolk, Chemist.
1888. Lundholm, Carl O., 220, Winchester House, Old Broad Street, London, E.C., Explosives Works Manager.
- O.M. Lunge, Dr. G., Carmenstrasse 37, Zürich, Switzerland, Professor of Chemistry.
1885. Lupton, Sydney, 102, Park Street, Grosvenor Square, London, W.
1884. Luthy, Otto, Haekensack, N.J., U.S.A., Analytical Chemist.
1903. Lye, Ernest B., Legrave Hall, near Luton, Beds, Straw Plait Dyer and Bleacher.
1885. Lye, W. T., Legrave Hall, near Luton, Beds, Straw Dyer.
1915. Lyle, C. E. Leonard, 21, Mineing Lane, London, E.C., Sugar Refiner.
1884. Lyle, James, 23, Mainsfield Road, Ilford, Sugar Refiner.
1916. Lyman, Arthur, c/o Lyman's Ltd., 344, St. Paul Street West, Montreal, Canada, Wholesale Druggist.
1896. Lymn, Arthur H., 40, Westminster Palace Gardens, S.W., Consulting Chemical and Gas Engineer.
1899. Lynn, R. Rankine, 8, Windsor Quadrant, Kelvin-side, Glasgow, Chemical Engineer.
1906. Lyons, Robert H., c/o Canadian Explosives, Ltd., Beloeil Station, Quebec, Canada, Chemist.
- O.M. Lytle, A. M., North of Ireland Chemical Co., Ltd., 34, Victoria Street, Belfast, Ireland, Chemical Manufacturer.

1908. Maas, Milton A., 92, William Street, New York City, U.S.A., Manufacturing Chemist.
1911. Mabbitt, Alan T., 3, Wallwood Road, Leytonstone Essex, Analytical Chemist.
1887. Mabery, Prof. Chas. F., Case School of Applied Science, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1891. Macadam, Herbert E., Dalkeith, Glengall Road, Woodford Green, Essex, Manure Works Manager.
1894. Macadam, Stevenson, 55, York Place, Edinburgh, Analytical Chemist.
1912. McAfee, Dr. A. M., c/o The Gulf Refining Co., Port Arthur, Texas, U.S.A., Chemist.
1917. McAlley, James, "Noreot," Church Lane, Whitefield, nr. Manchester, General Manager.
1894. McAlley, Robt., Bankside, Falkirk, Scotland, Paint Works Manager.
1892. Macara, Thos., jun., 20, Denton Road, Stroud Green, N., Chemist.
1912. McArlly, T. P., Mount Lyell Mining and Railway Co., Queenstown, Tasmania, Chemist and Assayer.
1917. McArthur, Donald N., Chemistry Dept., West of Scotland Agricultural College, 6, Blythswood Square, Glasgow, Research Chemist.
1887. McArthur, James B., Price's Patent Candle Co., Limited, Belmont Works, Battersea, S.W., Chemist.
- O.M. McArthur, J. S., Loch Lomond Radium Works, Balloch, Dumbartonshire, Consulting Chemist and Metallurgist.
1901. Macarthur, Jno. S., 15, St. John's Road, Pollokshields, Glasgow, Paint and Varnish Manufacturer.
1892. McArthur, Thos., 711, Tower Building, Water Street, Liverpool, Drysalter and Drywood Extractor.
1917. Macaulay, James R., 2378, Hutchinson Street, Outremont, Quebec, Canada, Chemist.
1912. Macaulay, John W., Evermonde, 10, Holmlands, Monkseaton, Northumberland, Metallurgical Chemist.
1898. MacCallum, D. A., 389, Central Chambers, 93, Hope Street, Glasgow, Chemist.
- O.M. MacCallum, Sir J. M., M.P., Southdene, Paisley, Scotland, Soap Manufacturer.

1914. McCarthy, Robt. A., Bertram Street, Mortlake, Sydney, N.S.W., Australia, Gas Chemist.
1917. McCauley, John J., "Sunnyholme," Fairfield Road, Latchford, W., Warrington, Technical Chemist.
1905. McCaw, Lt.-Col. W. D., Library, Surgeon General's Office, Washington, D.C., U.S.A., Officer, Medical Department, U.S. Army.
1915. McCleak, G. E., Curhar Crescent, Station Road, Cliffe, Kent, Explosives Chemist.
1905. McCleary, Wm., 61, Station Road, Pendlebury, near Manchester, Finisher.
1910. McColl, A. L., 60, Addingham Road, Mossley Hill, Liverpool, Chemist.
1913. McCrady, McH., 9, St. James Street, Montreal, Canada, Chemist and Bacteriologist.
1897. McCrae, Dr. John, Government Laboratories, P.O. Box 1080, Johannesburg, Transvaal, Government Analyst.
1898. McCreath, Wm. D., Quantock Vale Cider Works, North Petherton, Bridgewater, Cider Manufacturer.
1900. McCulloch, John, Glencee, Lostock Gralam, near Northwich, Cheshire, Chemical Engineer.
1911. McCulloch, Norman G., Rhodes Works, Rhodes, Manchester, Chemist and Calico Printer.
1903. McCully, R. E. J., c/o The Indian Cement Co., Porbandar, Kathiawar, India, Analytical Chemist.
1916. McDermott, F. A., c/o Corby Co., Station K., Washington, D.C., U.S.A., Research Chemist.
1910. Macdonald, Alexander, Netherlea, Matilda Road, Pollokshields, Glasgow, Manufacturing Chemist.
1912. Macdonald, Allan D., "Belgrano," Milngavie, near Glasgow, Manufacturing Chemist.
- O.M. Macdonald, Andrew, 72, Great Clyde Street, Glasgow.
1912. McDonald, Donald, 95, Clarence Gate Gardens, Regent's Park, London, N.W., Analytical Chemist.
1897. MacDonald, G. W., Whitefriars, Rochester, Kent Chief Explosives Research Chemist (Curtis's and Harvey, Ltd.).
1910. Macdonald, Major J. L. A., 13, Howard Place, St. Andrews, Fife, Scotland.
- O.M. MacDonald, J. W., c/o Henry Tate and Sons, Ltd., Thames Sugar Refinery, Silvertown, E., Analytical Chemist.
- O.M. McDonald, T. McG., Wahlabo Estate, St. Vincent, West Indies, Sugar Chemist.
1916. MacDougall, A. J., Toronto Power Co., 12, Adelaide Street East, Toronto, Canada, Mechanical Engineer.
1890. McDougall, J. T., St. Lawrence, Isle of Wight, Manufacturing Chemist.
1906. McDowall, Wm., Oficina Santa Isabel, Tocopilla, Chile, Analytical Chemist.
1889. MacEwan, Peter, 64, Southwood Lane, Highgate, N., Editor of "Chemist and Druggist."
1901. McEwen, Duncan C., c/o Chosen Gold Mines, Ltd., Kok-Kang-Kol Mine, Chung-An, Korea, Metallurgical Chemist.
1917. McEwen, Gordon C., c/o Imperial Varnish and Colour Co., Ltd., Morse Street, Toronto, Canada, Chemist.
1914. McFadyen, F. H., Batavia Rubber Company, Batavia, N.Y., U.S.A., Chemist.
1902. McFarland, Alan R., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
1916. Macfarlane, C. W. C., 116, Forth Street, Pollokshields, Glasgow, Analytical Chemist.
1910. McFarlane, John, 6, Gordon Terrace, Shettleston, Glasgow, Metallurgist.
1893. McGhie, T. Burns, c/o Dr. Goodall, 1, Annandale Road, East Greenwich, S.E., Metallurgist.
1904. McGill, Dr. A., 317, Queen Street, Ottawa, Canada, Analytical Chemist.
1899. McGillivray, Wm. A., c/o Swansea Safety Fuse Factory, Pipe House Wharf, Swansea, Works Manager.
1887. McGlashan, John, Post Office, Tolodi Balapur, Dist. Chanda, C.P., India, Technical Chemist.
1917. MacGregor, Jas., c/o E. Scott and Co., Ltd., 19, Waterloo Street, Glasgow, Joint Managing Director.
1896. Mellhiney, Dr. Parker C., 50, East 41st Street, New York City, U.S.A., Chemist.
- O.M. Mellowaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.
- O.M. McIndoe, G. D., Ness Street, Invercargill, New Zealand, Public Analyst and Consulting Chemist.
1917. MacInnes, Ronald, 17, Shrewsbury Road, New Southgate, London, N., Departmental Manager.
1903. MacIntire, Benj. Gould, c/o du Pont Powder Co., Georgetown, S.C., U.S.A., Chemist.
1916. McIntosh, J. G., 9, Parsonage Street, Cubitt Town, E., Technical Chemist.
1909. McIntyre, George D., 536, Notre Dame de Grace Avenue, Montreal, Canada, Technical Chemist.
1916. Mack, G. A., 19, Havergal Street, Runcorn, Cheshire, Works Chemist.
1910. Mackay, Angus, Laboratory, Wellpark Brewery, Glasgow, Brewer's Chemist.
1911. Mackay, F., Oficina Agua Santa, Negreiros, Iquique, Chile, Analytical Chemist.
1912. McKechnie, Alex., Chad Hill Cottage, Edgbaston, Birmingham, Copper Smelter.
1904. MacKeehnie, R. D., c/o British Aluminium Co., Ltd., Larne Harbour, co. Antrim, Ireland, Chemical Engineer.
1917. McKee, Ralph H., 187, Bergen Avenue, Ridgefield Park, N.J., U.S.A., Research Chemist.
1887. McKellar, W. G., c/o United Alkali Co., Ltd., St. Rollox Works, Glasgow, Technical Chemist.
1899. McKenzie, Alex. H., 17, North Street, North Adams, Mass., U.S.A., Colour Mixer.
1909. Mackenzie, Kenneth G., c/o The Texas Co., 17, Battery Place, New York, U.S.A., Chemist.
1917. McKenzie, Tom M., c/o Anglo Mexican Petroleum Co., Ltd., Finsbury Court, Finsbury Pavement, E.C., Chemist.
1893. McKerrow, C. A., 50, Great Russell Street, W.C.; and (Journals) c/o Mitchells, Ashworth and Co., 23-24, Old Bailey, London, E.C., Consulting Chemist.
1893. McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1891. Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
1916. Mackie, Wm., c/o Mrs. French, 219, Sydenham Road, Sydenham, London, S.E., Ironworks Chemist.
1912. McKillop, G. F., Oilworks, Broxburn, West Lothian, Scotland, Works Chemist.
1890. McKillop, Jno., c/o W. Muller, 69A, Great Queen Street, Kingsway, W.C., Metallurgist.
1902. McKim, Wm., 37, Fairview Street, Yonkers, N.Y., U.S.A., Colour Maker.
1915. MacKusick, M. H., The Rubber Regenerating Co., Ltd., Westinghouse Road, Trafford Park, Manchester, Managing Director.
1916. MacLachlan, H. F., Hillcrest Oil Co., Ltd.; and (Journals) Woodend, Styal, Cheshire, Managing Director.
1908. McLaren, Alex., c/o W. P. Hartley, Aintree, Liverpool, Analytical Chemist.
1908. McLaren, Alex. W., Ramsden Dock, Barrow-in-Furness, Analytical Chemist.
1916. McLaren, Geo., 146, Dukes Avenue, Muswell Hill, N., Analytical Chemist.
1898. McLaurin, Robt., Homesteads, Cambusbarron, Stirling, Chemist.
1916. MacLean, Dr. A. R. M., 369, Mance Street, Montreal, Canada, Chemist.
1905. McLellan, Basil G., c/o Rowntree and Co., Ltd., The Cocoa Works, York, Technical Chemist.
1908. Macleod, Alex., Mount Pleasant, Old Kilpatrick, Dumbartonshire, Analytical Chemist.
1914. MacLeod, Fred. L., 694, Duke Street, Glasgow, Chemical Manufacturer.
1892. Macleod, Jas., Clairmont, 54, Albert Drive, Pollokshields, Glasgow, Manager.

1912. McMaster, Prof. Le Roy, Washington University, St. Louis, Mo., U.S.A., Assoc. Prof. of Chemistry.
1904. McMullen, Alan, Saint James' Gate, Dublin, Ireland, Brewer.
1895. McMurtry, G. C., Templemore, Richmond, Nelson, New Zealand, Manager.
- O.M. Macnab, W., 10, Cromwell Crescent, London, S.W., Analytical Chemist.
1907. McNaughton, Wm. G., Port Edwards, Wis., U.S.A., Chemist.
1908. McQueen, James, jun., No. 3, Staff Quarters, Dornock, Dumfriesshire, Chemical Manufacturer.
1912. McRae, J. A., 184, University Avenue, Kingston, Ont., Canada, Research Chemist.
1914. McTavish, D. D., 626, Roslyn Avenue, Westmount, Quebec, Canada, General Manager (Canadian Carbide Co.).
1909. McWhirter, James, c/o Wm. Beardmore and Co., Laboratory, Parkhead Forge, Glasgow, Metallurgical Chemist.
1910. Madge, Norman, 406, West Fifth Avenue, Roselle, N.J., U.S.A., Chemist.
1912. Main, Hugh, Almondaie, Buckingham Road, South Woodford, Essex, Analytical Chemist.
1898. Main, Wm., Piermont, N.Y., U.S.A., Chemist.
1915. Maitland, Prof. W., Robert Gordon's Technical College, Aberdeen, Professor of Chemistry.
1905. Major, Ernest, c/o Major Bros. and Co., Johnstone's Bay, Balmain, Sydney, N.S.W., Paint and Chemical Manufacturer.
- O.M. Major, J. Lewis, Sculcoates, Hull, Tar Distiller and Chemical Manufacturer.
1910. Male, C. E., c/o Bankoku Toryo Seizosho, P.O. Box No. 141, Kobe, Japan, Chemist.
1886. Mallinckrodt, Edw., Mallinckrodt Chemical Works, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1916. Malpas, A. E., "Inglebrook," Flint, North Wales, Manager (Perchlorate Works).
1915. Manahan, E. H., Marris Avenue, and Elm Road, Mountain Lakes, N.J., U.S.A., Manager (J. C. Wiarda and Co.).
1912. Manley, Chas. E., 8, Wilmington Gardens, Barking, Essex, Paint and Colour Works Manager.
1917. Manley, John W., "Woodbury," New Barnet, Herts, Electrical Engineer.
1893. Mann, Harold H., Agricultural College, Poona, Bombay, India, Research Chemist.
1899. Mann, Jas. S., 19, Stoford Road, Upton Manor, Essex, Analyst.
1891. Mann, John C., 33, Nicholls Street, West Bromwich, Staffs, Chemist.
1914. Mann, Wilfred G., 37, Parliament Street, Westminster, S.W., Chemical Engineer.
1914. Mann, William, Messrs. Mann and Cook, 27, St. Mary Axe, London, E.C., Oil and Chemical Merchant.
1892. Mansbridge, Wm., 4, Norwich Road, Wavetree, Liverpool, Chemist.
1915. Mansfield, John F., 433, Beverley Road, Hull, Manufacturer of Oils and Fats.
1916. Marcan, A., Sapatum Road, Bangkok, Siam, Chief Assayer, Royal Siamese Mint.
1883. Markel, Dr. K. E., 20, Queen's Gate Terrace, South Kensington, S.W., Technical Chemist.
1916. Marks, H. P., 3, Cranley Mansions, Muswell Hill, N., Analytical Chemist.
1905. Marland, Percy, Kempfield House, Knottingley, Yorks, Technical Chemist.
1905. Marlatt, Wilbur T., Oakville, Ont., Canada, Leather Manufacturer.
1914. Marples, Morris E., 20A, Belvedere Road, Upper Norwood, London, S.E., Chemist.
1916. Marriott, A. W., 21, Tennyson Street, Nottingham, Analytical Chemist.
1904. Marris, H. C., 68, Schlüsselsburg Prospekt, Petrograd, Russia, Analytical Chemist.
1901. Marsden, Dr. Fred., Technical Institute, Madura, South India, Chemist.
1906. Marsden, Oliver, Manor Road Mill, Victoria Road, Leeds, Cashier.
- O.M. Marsh, J. T., Ammonia Soda Works, Fleetwood, Lancashire, Chemist.
1883. Marsh, W., Union Alkali Co., Soho Works, Ancoats, Manchester, Chemical Manufacturer.
1895. Marshall, Arthur, Waverley Cottage, Naini Tal, India, Chief Chemical Examiner.
1895. Marshall, Francis G., 56, Bewick Road, Gateshead, Technical Chemist.
1908. Marshall, John, Cudbear Street, Hunslet, Leeds, Dyeware Manufacturer.
1917. Marshall, Joseph, 11, George Road, West Bridgford, Nottingham, Research Chemist (Boots Pure Drug Co.).
1913. Marshall, Philip W., c/o The Fred. Crane Chemical Co., Armoury Close, Bordesley Green, Birmingham, Lacquer Manufacturer (retired).
1917. Marshall, Reginald E., No. 29 Black, Gaitlebridge, Greta, Works Chemist.
1883. Marshall, Wm., Laboratory, Ladybrook Road, Cheadle Hulme, Cheshire, Dyer.
1884. Marshall, Wm., 9, Castello Avenue, Putney Park, S.W., Analytical Chemist.
1904. Marston, John P., 247, Atlantic Avenue, Boston, Mass., U.S.A., Merchant.
1894. Martin, Alex. M., Hillview, Twechar by Glasgow, Analytical Chemist.
1895. Martin, Chas. H., 50, Longmead Road, Claremont, Pendleton, Manchester, Oil and Soap Works Manager.
1913. Martin, Edwin J., c/o Jas. Martin and Sons, Luton, Beds, Bleacher and Dyer.
1911. Martin, Dr. G., Co-operative Wholesale Society, Ltd., Research Dept., 109, Corporation Street, Manchester, Science Teacher and Industrial Chemist.
1916. Martin, Sam W., "Wood Grange," Station Road, Brimington, Chemical Works Manager.
1917. Martin, Thomas, 18, Winifred Road, Urmston, Manchester, Works Chemist.
1916. Martin, V. M., 68, Upper Thames Street, London, E.C., Fur Skin Dyer and Dresser.
1916. Martin, Dr. Wm., c/o Brady and Martin, Ltd., Northumberland Road, Newcastle-on-Tyne.
1899. Martin, Wm. E., 111, Bellevue Road, Durban, Natal, South Africa, Chemist.
1887. Martineau, Sydney, Streatham Grove, Norwood, S.E., Sugar Chemist.
1894. Martyn, T. Graham, Box 5, Maraishburg, Transvaal, South Africa, Metallurgist.
1909. Marx, Robert J., 133-139, Finsbury Pavement, London, E.C., Engineer.
1904. Mason, Dr. Edward D., 32, Vernon Road, Edgbaston, Birmingham, Scientific Apparatus Dealer.
1911. Mason, Francis A., c/o Murphy and Lonsdale, 4, Queen Square, Leeds, Analytical Chemist.
1915. Mason, Dr. Fredk. A., 21, Queen Square, London, W.C., Demonstrator in Chemistry.
1906. Mason, Dr. Frederic S., 90, Beckman Street, New York City, U.S.A., Manufacturing Chemist.
1887. Mason, J. Francis, Eynsham Hall, Witney, Oxon.
1914. Mason, William O. S., Bankside, Meopham, near Gravesend, Kent, Analytical Chemist.
1915. Masse, René, 12, Rue de Clichy, Paris, France, President (Gas Society).
- O.M. Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.
1908. Masson, R. Duncan, c/o Messrs. R. Silcock and Sons, Stanley Hall, Union Street, Liverpool, Analytical Chemist.
1902. Masujima, Prof. Bunjiro, c/o K. Takebe, 16, Gizenbocho, Azabuku, Tokyo, Japan, Prof. of Applied Chemistry.
1910. Matchet, Andrew S., 13, Bute Gardens, Muirend, Cathcart, Glasgow, Analytical Chemist.
1911. Mather, Hubert, Lonsdale Terrace, Whitefield, Lancashire, Chemist.
1900. Mather, Wm., c/o The Standard Chemical Iron and Lumber Co., Montreal, Canada, Chemist.
1907. Matheson, A. Greville E., 9, Mossband, Greta, near Carlisle, Engineer.

1890. Matheson, W. J., c/o Cassella Color Co., 182, Front Street, New York City, U.S.A., Chemical Merchant.
1901. Mathew, W. E. B. de Vere, "Dinham," Hillside Gardens, Wallington, Surrey, Analytical Chemist.
1898. Mathewson, E. P., Royal Bank Building, 8, King Street East, Toronto, Canada, Metallurgist.
1888. Mátos, Dr. Louis J., (Comms.) 103, North 19th Street, East Orange, N.J., and (Jnls.) c/o Cassella Color Co., 182-4, Front Street, New York City, U.S.A., Chemist.
1896. Matsui, G., 10, Nishikatomachi, Hongo, Tokyo, Japan, Chemical Engineer.
1912. Matthewman, Fred. P., Analyst's Office, L.B. and S.C. Railway Co., Brighton, Chief Chemist.
- O.M. Matthews, Chas. G., 31, Stapenhill Road, Burton-on-Trent, Brewing Chemist.
1907. Matthews, Dr. F. E., Aberdeen House, Flat No. 1, 211, Adelaide Road, Swiss Cottage, N.W., Technical Research Chemist.
1899. Matthews, Dr. J. Merritt, 50, East 41st Street, New York City, U.S.A., Professor of Chemistry and Dyeing.
1903. Maxim, Hudson, 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A., Chemist and Mechanical Engineer.
1916. Maxted, Dr. Edw. B., 63, Highgate Road, Walsall, Staffs, Chemist.
1894. Maxwell, Jno., Solway Chemical Works, Silloth, Cumberland, Chemical Manure Manufacturer.
1903. Maxwell, Orin P., c/o West Virginia Pulp and Paper Co., Luke, Md., U.S.A., Chemist.
1911. May, Clarence E., 520, South Park Avenue, Bloomington, Ind., U.S.A.
1914. May, Dr. Percy, 126, Cazenove Road, Stamford Hill, London, N., Chemist.
1884. Mayenfeld, Dr. E. von Salis. See Salis-Mayenfeld, Dr. E. von.
1903. Mayer, Andrew, jun., 8210, Ridge Boulevard, Brooklyn, N.Y., U.S.A., Chemist.
1896. Mayfield, A. S., Oakdene, Newland Park, Hull, Analyst.
1892. Mayfield, H. B., Normanhurst, Mundy Street, Heanor, near Nottingham, Dyer.
1885. Mayhew, E. W. A., Library, Technical College, Perth, Western Australia, Manufacturing Chemist.
1916. Mayo, Chas. R., 155, Dashwood House, New Broad Street, E.C., Consulting Engineer.
1909. Meanwell, Chas. W., 15, Woodlands Crescent, Muswell Hill Road, London, N., Analytical Chemist.
1916. Meek, R. H., 1331, Salisbury Drive, Vancouver, B.C., Canada, Chief Dairy and Food Inspector.
1896. Meggitt, Loxley, c/o Co-operative Wholesale Society, Ltd., Irlam, near Manchester, Analytical Chemist.
1901. Meier, Dr. Franz, c/o Society of Chemical Industry in Basle, Basle, Switzerland, Chemist.
1888. Meikle, John, S., Melrose Street, Great Western Road, Glasgow, Journalist.
1915. Meister, Fred J., Laboratory, Distillers' Co., Ltd., Menstrie, Scotland, Analytical Chemist.
1902. Mecher, Arthur C., 58, Bowen Street, Newton Centre, Mass., U.S.A., Research Chemist.
1912. Melling, S. E., Bank House, The Cliff, Higher Broughton, Manchester, Analytical Chemist.
- O.M. Mellon, W. W., Woodlands, Blackrock, Co. Dublin, Ireland, Manufacturing Chemist.
1910. Mellor, Dr. Joseph W., Sandon House, Regent Street, Stoke-on-Trent, Ceramic Chemist.
1917. Melvin, Geo. M. A., c/o Australian Explosives and Chemical Co., Ltd., 135, William Street, Melbourne, Australia, General Manager.
1915. Mendonça, M. S. de, 100, Rua S. Julião, Lisbon, Portugal, Chemist.
1912. Mennell, Harold, 41, Wolverton Road, Stony-Stratford, Bucks, Analytical Chemist.
1893. Mensching, Dr. C., Journals to Mersey Chemical Works, Bromborough Port, Birkenhead, Chemist.
1915. Menzies, R. C., c/o A. Beake Roberts & Co., Ltd., Carpenters Road, Stratford, E., Chemist.
1892. Mercer, C. A., 34, Camomile Street, London, E.C., Chemical Apparatus Maker.
1905. Merck, George, Merck and Co., 45, Park Place, New York City, U.S.A., Manufacturing Chemist.
1916. Merreywether, J. E., 27, Agnes Street Meadows, Nottingham, Analytical Chemist.
1899. Merrill, Frank H., 2420, Ocean View Avenue, Los Angeles, Cal., U.S.A., Factory Superintendent.
1906. Merrils, Fred. J., 25, Figtree Lane, Sheffield, Analytical Chemist.
1909. Merriman, C. E. B., 74, Trent Boulevard, West Bridgford, Nottingham, Technical Chemist.
1909. Merriman, H. J., 214, Victoria Park Road, South Hackney, N.E., Research Chemist.
1905. Merrin, A. C., 194-200, Bishopsgate, London, E.C., Assistant Editor and Analyst.
1904. Merry, Jno. B., 74, Park Hill Road, Harborne, Birmingham, Metallurgical Chemist.
1903. Mersan, Ferdinand de, Fairfield, Chestnut Avenue, Boston Spa, Yorks, Chemist.
1905. Merz, Eugene, Newark, N.J., U.S.A., Superintendent, Heller and Merz Co.
1897. Meslans, Prof. M., 6, Rue de Navarin, Paris, France, Professor of Chemistry.
- O.M. Messel, Dr. R., F.R.S., 147, Victoria Street, London, S.W., Chemical Manufacturer.
1899. Metcalf, Howard F., Farr Alpaca Co., Holyoke, Mass., U.S.A.
1886. Metcalf, Jno., Moorfield Chemical Works, Altham, near Acerington, Tar Distiller.
1908. Metcalfe, Ernest D., Messrs. Curtis's and Harvey, Ltd., Cannon Street House, London, E.C., Secretary.
1906. Methley, Bernard, Ferndale, Moorgate, Rotherham, Yorks, Engineering Chemist.
1898. Metz, Herman A., P.O. Box 753, New York City, U.S.A., Chemical Merchant.
1917. Metzger, F. J., 120, Broadway, New York City, U.S.A., Professor of Chemical Engineering.
1900. Mewborne, Robt. G., c/o Kentucky Tobacco Products Co., Louisville, Ky., U.S.A., Chemist.
1907. Meyer, Dr. Erwin, c/o Morgan and Wright, Detroit, Mich., U.S.A., Chemist.
1902. Meyrick, L. J., 137, City Road, Birmingham, Assistant Analyst.
1915. Miall, Dr. S., 28, Belsize Grove, Hampstead, N.W., Chairman of the Grimsdown Lead Co.
1912. Michie, Arthur C., The Wallsend Laboratories, Wallsend-on-Tyne, Technical Chemist.
1909. Michie, John L., c/o Peter Scott and Co., Limited, Buccleuch Street, Hawick, Scotland.
1907. Micklethwait, Miss Frances M. G., 17, St. Mary's Terrace, Paddington, W., Chemist.
1916. Middleditch, B., Hillside, Peterborough Hill, Harrow, Chemistry Master.
1911. Middlemass, Alphonso, 59, Promenade, Portobello, Midlothian, Works Chemist.
1904. Mighill, Dr. Thos. A., 37, Wareham Street, Boston, Mass., U.S.A., Chemist.
1896. Miles, G. Wellington, jun., Room 214, 88, Broad Street, Boston, Mass., U.S.A., Analytical Chemist.
1889. Milestone, W. C., 45, Heathfield Road, Wandsworth Common, S.W., Chemical Works Manager.
1916. Millar, A. Falconer, 28, Victoria Street, London, S.W., Chemical Engineer.
1916. Millar, E. T., Douglas House, Birmingham Road, West Bromwich, Chemist.
1899. Millar, Jas. H., P.O. Box 4975, Johannesburg, Transvaal, Manufacturing and Analytical Chemist.
1909. Millar, Jas. Hill, Chief Chemist's Laboratory, St. James' Gate Brewery, Dublin, Chemist.
1883. Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
- O.M. Miller, E. V., Sugar Works, Chelsea, Auckland, New Zealand, Sugar Works Chemist.
1914. Miller, Eric J., Carnub Club, Perambur Barracks, Madras, India, Chemist.
1917. Miller, Frank, 21, Ossington Villas, Sherwood Street, Nottingham, Works Chemist (Boots Pure Drug. Co.).

1889. Miller, Geo., Thornlea, Beaconsfield Road, Farnworth, Widnes, Technical Chemist.
1893. Miller, Dr. Harry E., 305, Palm Avenue, Oakland, Cal., U.S.A., Chemist.
1894. Miller, Dr. John A., 44-45, Lewis Block, Buffalo, N.Y., U.S.A., Consulting Chemist, to State of N.Y.
1888. Miller, J. Hopkins, 86, North Frederick Street, Glasgow, Dyeworks Chemist.
1889. Miller, Jno. Poynter, Sandilands Chemical Works Aberdeen, Technical Chemist.
1901. Miller, Stuart B., c/o Du Pont Powder Co., High Explosives Operating Dept., Wilmington, Del., U.S.A., Chemical Engineer.
1916. Miller-Jones, T., Invieta Mills, Bow Common Lane, London, E., Manufacturing Chemist.
1901. Miller, Dr. W. Lash, 50, St. Alban Street, Toronto, Canada, Associate Professor of Physical Chemistry.
1884. Miller, W. M., Caledonia Estate, Prov. Wellesley, Penang, S.S., Sugar Chemist.
1902. Milligan, R. E., New York Continental Jewell Filtration Co., 15, Broad Street, New York City, U.S.A., Chemical Engineer.
- O.M. Mills, Prof. E. J., F.R.S., 64, Twyford Avenue, West Acton, W., Emeritus Professor of Technical Chemistry and Consulting Chemist.
1916. Mills, Frederick Peter, Colliery Rescue Station, 854, Scotswood Road, Newcastle-on-Tyne, Mining Engineer.
1904. Mills, Dr. J. E., University of South Carolina, Columbia, S.C., U.S.A., Analytical and Consulting Chemist.
1916. Mills, Willie G., "Sylvan," Bramford, near Ipswich, Suffolk, Works Manager.
1905. Mills, Wm. Henry, 120, Broadway, New York City, U.S.A., Merchant.
1916. Mills, Dr. Wm. S., Research Dept., Levinstein, Ltd., Blackley, Manchester, Research Chemist.
1915. Milne, John, 1, St. Mary's Place, Inverurie, Aberdeenshire, Merchant.
1905. Milne, Thomas, c/o The Gas Light and Coke Co., Ltd., Finsbury Court, Finsbury Pavement, London, E.C., Chemical Products Salesman.
1916. Milner, David W., Well Close Place, Lofthouse, Wakefield, Works Chemist.
1903. Milnes, Cresswell, The Cedars, Holborough, near Rochester, Cement Works Manager.
1887. Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
1902. Milnes, Ernest E., Park Print Works, Halifax, Yorks, Chemist.
1909. Mindeff, Chas., c/o American Smelting and Refining Co., Maurer, N.J., U.S.A., Chemist.
1895. Miner, Harlan S., c/o Welsbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
1916. Mingaye, J. C. H., Chemical Laboratory, Dept of Mines; (Journals) Campbell Street, Parramatta, N.S.W., Australia, Chemist and Assayer.
1915. Misell, D., c/o R. Lane-Hall and Co., 4, Lloyds' Avenue, London, E.C., Chemical Merchant.
1895. Mitchell, Chas. A., c/o Beanfoy and Co., South Lambeth Road, S.W., Analyst.
1898. Mitchell, G. D. H., 309, North Fullerton Avenue, Montclair, N.J., U.S.A., Chemist.
1917. Mitchell, Percy, Hillside, Wheatthampstead, Herts, Works Chemist.
1917. Mitchley, John W., A4, Staff Quarters, Easttriggs, Annan, N.B., Chemical Engineer.
1904. Mitsugi, R., c/o Tokyo Gas Co., Kanda, Tokyo, Japan, Chemist.
- O.M. Mitting, E. Kennard, 38, Harold Road, Norwood, S.E., Technical Chemist.
1909. Miyoshi, K., Osaka Gas Works, Iwasakicho, Nishiku, Osaka, Japan, Engineer.
1905. Modi, Dr. E. M., Meher Buildings, Tardeo, Bombay, India, Manufacturing and Analytical Chemist.
1917. Mody, Frederick W., 12, Park Avenue, Long-sight, Manchester, Works Chemist.
1910. Moe, Carl, The Pine Tree Inn, Bogalusa, La., U.S.A., Chemist.
1906. Moe, Eldor H., Box 266, Salt Lake City, Utah, U.S.A., Chemist.
1914. Moffitt, Francis A., 72, Hawley Street, Binghamton, N.Y., U.S.A., Chemist.
- O.M. Mohr, Dr. B., 69A, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
1894. Mole, Herbert B., Royal Albert Brewery, Queen's Road, Reading, Brewer.
1901. Mond, Dr. Albert L., c/o Hubers and Mond, 19, Southampton Buildings, Chancery Lane, London, W.C., Chemical Engineer.
1899. Mond, Emile S., 22, Hyde Park Square, London, W., Technical Chemist.
1891. Mond, Dr. Robt. L., Cembe Park, near Sevenoaks, Kent, Chemist.
1906. Monier-Williams, G. W., 32, St. Leonard's Terrace, Chelsea, S.W.
1908. Monk, Chas. W., 102, Bloomfield Road, Plumstead, Kent, Chemist.
1909. Monk, Reginald Hill, 388, Grosvenor Avenue, Westmount, P.Q., Canada, Chemical Engineer.
1916. Montgomerie, J. A., Maryfield, Central Avenue, Cambuslang, Chemist.
1890. Moodie, Wm. E., Alexandria Works, Alexandria, Scotland, Analytical Chemist.
1905. Moody, Dr. Gerald T., Lorne House, North Dulwich, S.E., Barrister-at-Law.
1898. Moody, Dr. Herbert R., College of the City of New York, and (Journals) 330, Convent Avenue, New York City, U.S.A., Professor of Chemistry.
1903. Mooney, F. Morgan, 118, Pembroke Road, Dublin, Chemical Manure Manufacturer.
1902. Mooney, Luke, Box 435, Woodbridge, N.J., U.S.A.,
1887. Moore, Chas. C., 33, Clarendon Road, Garston, Liverpool, Chemist.
1901. Moore, Dr. Chas. W., c/o Crosfield and Sons, Ltd., Laboratory, Warrington, Chemist.
1907. Moore, Ernest P., 34, Jackson Street East, Hamilton, Ont., Canada, Chemist.
1911. Moore, 2nd Lieut. Ernest W., 3rd Battalion Middlesex Regt., Salonika E.F., Analytical Chemist. On Active Service; retain Journals.
1902. Moore, Fred., Canadian Explosives, Ltd., Victoria, B.C., Canada, Manufacturing Chemist.
1906. Moore, F. H., Messrs. G. H. Ogston and Moore, 87-89, Aldgate, London, E., Analytical Chemist.
1892. Moore, Dr. Geo. D., 201, Salisbury Street, Worcester, Mass., U.S.A., Professor of Chemistry.
1914. Moore, Harold, c/o Mirreles, Bickerton, and Day, Hazel Grove, Stockport, Chemist.
1916. Moore, Jos. H., Main Street, Randalstown, co. Antrim, Ireland, Textile Chemist and Cloth Bleacher.
1912. Moore, Joseph W., Kinderton House, Runcorn, Works Chemist.
1914. Moore, Lawrence, Stoneywood, 22, Welbeck Street, Wakefield, Dyer.
1905. Moore, Leslie R., 14, Elm Street, Concord, Mass., U.S.A., Chemist.
1899. Moore, Quintin, jun., Garrowbank House, Riddrie, Glasgow, Works Manager.
1885. Moore, R. T., 142, St. Vincent Street, Glasgow, Mining Engineer.
1899. Moore, Dr. Russell W., 121, Madison Avenue, New York City, U.S.A.; and Journals to University Library, Princeton, N.J., U.S.A., Chemist.
1890. Moore, Thos., 3, Tamworth Road, Sutton Coldfield, Birmingham, Analytical Chemist.
1917. Moore Tom S., Hillside, Egham, Surrey, Professor of Chemistry.
1910. Moorhouse, Samuel, 48, Oakworth Street, Blackley, Manchester, Secretary and Oil Specialist.
1903. Moran, Geo. A., 98, Massachusetts Avenue, North Andover, Mass., U.S.A., Chemist.
1916. Mordecai, W. E., 1, Craig-yr-Hesg, Berw Road, Pontypridd, Glem, Technical Chemist.
1902. More, Andrew, "Ellesmere," King's Road, Walton-on-Thames, Analytical Chemist.

1908. Morfev, Harold, c/o The Mitchell Main Colliery Co., Ltd., Wombwell, near Barnsley, Yorks, Manager of By-Products Works.
1901. Morgan, Dr. Gilbert T., F.R.S., City and Guilds Technical College, Leonard Street, Finsbury, E.C., Professor of Chemistry.
1912. Morgan, Sidney, Petaling Estate, Selangor, Federated Malay States, Analytical Chemist.
1906. Morgan, Thos., c/o R. H. Morgan and Co., Ltd., Custom House Buildings, Liverpool, Manufacturing Chemist.
1898. Morgan, T. M., 370, Wood Avenue, Westmount, Quebec, Canada, Cement Works Manager.
1916. Morgan, Trevor O., c/o Messrs. Levinstein, Ltd., Blackley, Manchester, Analytical Chemist.
- O.M. Moritz, Dr. E. R., 45, Great Tower Street, London, E.C., Brewing Chemist.
1885. Morley, Dr. H. Forster, 5, Lyndhurst Road, Hampstead, N.W., Professor of Chemistry.
1902. Morrell, Dr. R. S., Messrs. Mander Bros., Colour and Varnish Works, Wolverhampton, Chemist.
1884. Morrice, Jas. A., 1, Prince's Terrace, Dowanhill, Glasgow, Starch and Gum Manufacturer.
1906. Morris, A. H., 152, Chorley New Road, Bolton, Lanes, Brewer.
1898. Morris, Edgar F., Holly Bank, Roby, near Liverpool, Research Chemist.
1897. Morris, Harry, The Hall, Hexthorpe, Doncaster, Chemical Merchant.
1890. Morris, Herbert N., Alpha Works, Denton, near Manchester, Technical Chemist.
1903. Morris, Wm. J., 33, Prince Alfred Road, Wavertree, Liverpool, Chemist.
1911. Morrison, G. R., Oficina Reducto, Santa Catalina, Iquique, Chile, Chemist.
1910. Morrison, J. A. S., S. Esteourt Avenue, Headingley, Leeds, Leather Chemist.
1904. Morson, Thos. D., 14, Elm Street, Gray's Inn Road, London, W.C., Chemist.
1906. Morson, T. Pierre, 14, Elm Street, Gray's Inn Road, London, W.C., Chemical Manufacturer.
1916. Morton, Allan, 167, Trent Boulevard, West Bridgford, Nottingham, Technical Chemist.
1907. Morton, George A., "Silverbirch," Station Road, Wylde Green, Birmingham, Chemist and Works Manager.
1917. Morton, James, Dentonhill Works, Carlisle, Textile Manufacturer.
1897. Morton, Jno., North Road, St. Helens, Lancashire, Analytical Chemist.
1902. Mosbaugh, F. R., c/o Anglo-Canadian Leather Co., Huntsville, Ont., Canada, Chemist.
1911. Mosenthal, E. Macqueron de, 9, Rue Neuve, Versailles, France, Chemist.
1915. Moss, Gerald L., 13, Barkly Grove, Beeston, Leeds; Chemical Engineer.
1894. Moszczenski, John B., 216, Ovington Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist.
1897. Motion, Jno., c/o The Joseph Dixon Crucible Co., Jersey City, N.J., U.S.A., Assistant Superintendent.
1887. Moul, Frank, Aldersgate Chemical Works, Southall, Technical Chemist.
1898. Moulton, Prof. Chas. W., Vassar College, Poughkeepsie, N.Y., U.S.A., Professor of Chemistry.
1905. Moulton, Rt. Hon. Lord, K.C.B., G.B.E., F.R.S., 57, Onslow Square, London, S.W.
1915. Moulton, P. P., 49, The Mall, Faversham, Kent, Explosives Chemist.
1892. Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).
1905. Mrazsek, F. M., 31, West Cromwell Road, London, S.W., Consulting Chemist.
1890. Muir, Jas. Stanley, 23, Lilybank Gardens, Glasgow, Chemist.
1896. Mundy, Lionel, 27, Merton Road, Kensington, W., Importer of Unfermented Wines.
1914. Munn, W. F., 518, Main Street, East Orange, N.J., U.S.A., Chemist.
1887. Munroe, Prof. Chas. E., George Washington University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.
1900. Munton, Fred. T., c/o The Salt Union, Ltd., Engineer's Office, Winsford, Cheshire, Analytical Chemist.
1904. Murdoch, Alexander, Garden Suburb, Westerton, near Glasgow, Analytical Chemist.
1917. Murdoch, David S., 28, Craigpark Drive, Dennistoun, Glasgow, Analytical Chemist.
1886. Murdoch, R. H. M., Norwood, Saltecoats, Ayrshire, Explosives Chemist.
1899. Murphy, Albert J., 3 and 4, Queen Square, Leeds, Brewer's Chemist.
1901. Murray, Benjamin L., c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.
1903. Murray, Chas. B., 467, Perry Payne Building, Cleveland, Ohio, U.S.A., Chemist.
1914. Murray, John E., c/o Emerson Drug Co., 64, Spadina Avenue, Toronto, Canada, Laboratory Superintendent.
1898. Murray, Rd., c/o Brotherton and Co., Ltd., Ammonia Works, Holmes Street, Leeds, Analyst.
1908. Murray, Captain Thos. J., O.C. 71st Sanitary Section, B.E.F., Lecturer on Chemistry.
1916. Murray-Salamon, W. H., Ferry Road, Rainham, Essex, Chemical Manufacturer.
1905. Murrill, Dr. Paul L., Room 86, Chemists' Building 50, East 41st Street, New York, U.S.A., Superintendent.
- O.M. Muspratt, Dr. E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.
1894. Muspratt, Max, The Grange, Fulwood Park, Liverpool, Technical Chemist.
- O.M. Muspratt, S. K., Alkali Manufacturer.
1907. Musso, Louis A., Box 956, G.P.O., Sydney, N.S.W., Australia, Technical Chemist.
1911. Myers, Ernest M., "Greycourt," Harpfield, Stoke-on-Trent, Coke Oven Manager and Chemist.
1917. Myers, Francis W., c/o W. J. Bush & Co., Ltd., Ash Grove, Hackney, N.E., Works Chemist.
1917. Myers, Jos. W., 4, Balmoral Gardens, Monkseaton, Northumberland, Analytical Chemist.
1891. Myers, Dr. Wm. S., 25, Madison Avenue, New York City, U.S.A., Director.

N

1902. Naef, Dr. Ernest E., 16, Loughborough Road, West Bridgford, Notts, Chemist.
1913. Nagase, Denzo, c/o Japan Dyestuff Manufacturing Co., Ltd., Osaka, Japan, Engineer.
1917. Nagelvoort, Adriaan, 52, East 41st Street, New York City, U.S.A., Chemist.
1908. Nagle, J. C., c/o Nicholls, Nagle and Co., Ltd., Trafford Park, Manchester, Glucose and Starch Manufacturer.
1913. Nair, Valliyil G., Société Cotonnière du Tonkin, Nam-Dinh, Tonkin, French Indo-China, Chemist and Colourist.
1897. Nairn, Sir Michael, Bart., Dysart House, Fife, Linoleum Manufacturer.
1909. Nakai, S., Miike Colliery Office, Omuta-machi, Chikugo, Japan, Engineer.
1903. Nakayama, T., Kihō, near Fusan, Korea, Chemist.
1893. Napier, John W., Gas Works, Alloa, Scotland, Manager and Chemist.
1904. Napper, Sidney S., c/o S. Courtauld and Co., Ltd., Foleshill Road, Coventry, Chemist.
1897. Nash, L. Myddleton, Westlands, Princess Road, Finsbury Park, N., Industrial Chemist.
1910. Nash, N. C., Treleven, Darling Street, Balmain East, Sydney, N.S.W., Works Chemist.
1908. Nasmith, M. E., Curtis Bay Chemical Co., Curtis Bay, Md., U.S.A., Chemist.
1900. Nathan, Col. Sir Frederic L., 37, Cornwall Gardens, South Kensington, S.W.
1917. Naughton, Wm. J. S., Levinstein Ltd., Blackley, Manchester, Research Chemist.

1916. Naylor, J. H., Braemore, Flinn Lane, Frodsham, Cheshire, Explosives Works Manager.
- O.M. Naylor, W. A. H., The British Drug Houses, Ltd., 22-30, Graham Street, City Road, London, N., Manufacturing Chemist.
1909. Neal, C. S., Acme White Lead and Colour Works, Detroit, Mich., U.S.A., Manager.
1899. Neate, Percy J., 49, Frogna, Hampstead, N.W., Director of Cement Co.
1916. Neaverson, Lewis, Clough Edge, Halifax Old Road, Huddersfield, Teacher of Dyeing.
1905. Neff, Robert W., 22, India Square, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Neil, Dr. Archibald A., c/o Brunner, Mond, and Co., Ltd., Caxton House, Westminster, S.W., Chemical Engineer.
1890. Neill, Geo. D., 78, Drumfrah Road, Greenock, Sugar Refiner.
1898. Neilson, Alex. McG., Umbilo, Durban, Natal, Analytical Chemist.
1911. Neilson, R. G., c/o Anglo-Persian Oil Co., Ltd., Abadan, Persian Gulf (via Bombay), Assistant Works Manager.
1902. Neish, Dr. Arthur C., Columbia University, New York City, U.S.A., Chemist.
1911. Nello, Vincent, Baldwin's Hill, Loughton, Essex, Artists' Colour Manufacturer.
1917. Nelson, Colin McG., Casa Pirita, Minas de Rio Tinto, Huelva, Spain, Metallurgist.
1916. Nelson, Sir E. Montague, K.C.M.G., Emseote Mills, Warwick, Gelatine Manufacturer.
1916. Nelson, Percy S., 153, Holly Road, St. Albans, Christchurch, New Zealand, Assistant Chemist.
1913. Nesbitt, Cosby T., 18, Montrose Road, Sheffield, Metallurgical Chemist.
1906. Nestell, Raymond J., c/o Western Precipitation Co., 1016, West Ninth Street, Los Angeles, Cal., U.S.A., Analytical Chemist.
1902. Neumann, Dr. Edgar D. M., Chemical Supply Co., Barking Gas Works, Abbey Road, Barking, E.
- O.M. Newall, F. S., Washington Station R.S.O., Co. Durham, Chemical Manufacturer.
1905. Newall, Jos., Hill Cliffe, Heath Road, Runcorn, Cheshire, Chemist.
1889. Newberry, Spencer B., 818, Engineers' Building, Cleveland, Ohio, U.S.A., Manager.
- O.M. Newlands, W. P. R., 10, Criclado Avenue, Streatham Hill, S.W., Sugar Chemist.
1914. Newman, Alex. R., C.E.R.A. (Temp.), H.M.S. Erebus, c/o G.P.O., London, Chemical Engineer.
- O.M. Newton, Jno., Verney Road, Rotherhithe New Road, London, S.E., Manure Manufacturer.
1912. Newton, Leonard O., Sefnol Ltd., Westcombe Hill, Greenwich, S.E., Analytical Chemist.
1901. Nibelius, Axel W. T., The Engineers' Club, 32, West 40th Street, New York City, U.S.A., Chemist.
1916. Nicholl, George, 15, Prince's Road, Heaton Moor, Stockport, Director, Claus & Co., Ltd.
1915. Nicholls, H. V., c/o G. and C. Hoskins, Ltd., Eskbank Iron and Steel Works, Lithgow, N.S.W., Australia, Chemist.
1904. Nichols, C. W., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
1905. Nichols, E. Remington, 25, Broad Street, New York City, U.S.A., Treasurer (Nichols Chemical Co.).
1888. Nichols, Dr. Wm. H., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.
1905. Nichols, W. H., jun., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.
1916. Nicholson, Frank, The Brewery, Castle Street, Sunderland, Brewery Director.
1904. Nicholson, Wilfred E., Hunstet Chemical Works, Leeds, Chemical Manufacturer.
1897. Nicholson, Wm. J., Ardeer, Stevenston, Ayrshire, Chemist.
1917. Nicol, James, "Sunny Lawn," 25, Montague Road, Wimbledon, London, S.W., Chemist.
1903. Nicoll, Frank, c/o Messrs. F. Steiner and Co. Ltd., Church Works, Church, Lanes, Chemist.
1905. Nieghorn, Albert, 120, Mill Street, Toronto, Canada, Agent.
1900. Nield, J. H., c/o General Chemical Co., Edgewater, N.J., U.S.A., Superintendent.
1916. Nightingale, Ernest, 20, Swain Street, Hyde, Cheshire, Works Chemist.
- O.M. Nimmo, Jas., 35, Whitworth Road, South Norwood, S.E., Analytical Chemist.
1907. Nims, H. E., c/o The Fiberloid Co., Indian Orchard, Mass., U.S.A., Chemist.
1916. Nisbet, Edward T., Lambton and Hetton Collieries, Ltd., Cathedral Buildings, Dean Street, Newcastle-on-Tyne, Secretary.
1885. Nishigawa, T., 5, Hikawa Cho, Akasaka, Tokyo, Japan, Works Director and Chemical Engineer.
1898. Nishikawa, Dr. T., Dept. of Applied Chemistry, Kyushu Imp. University, Fukuoka, Japan, Prof. of Applied Chemistry.
1916. Nivling, Walter A., 185, Devonshire Street, Boston, Mass., U.S.A., Sales Manager.
- O.M. Noetting, Prof. Dr. E., Cengiopresso, Savona, Italy, Professor of Chemistry.
1917. Nordin, Chas., c/o Russian-American India Rubber Co., Treugolnik, Petrograd, Russia, Works Chemist.
- O.M. Norman, Sir Frederick J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.
1892. Norman, J. T., 23, Leadonhall Street, London, E.C., Consulting Chemist.
1913. Norman, T. Stanley, Lyndhurst, Runcorn, Cheshire, Chemical Manager.
1890. Norman-Bott, Dr. Wm., 64, Victoria Street, Westminster, London, S.W., Consulting Chemist.
1915. Norris, Edward W., c/o Levinstein, Ltd., Blackley, Manchester, Works Chemist.
1902. North, Barker, 33, Ashgrove, Great Horton Road, Bradford, Assistant Professor of Chemistry.
1915. Northing, H. C., Reenmore, Arklow, co. Wicklow, Ireland, Technical Chemist.
1916. Northwood, T. G., 22, Claremont Road, Woodsmoor, Stockport, Works Chemist.
1905. Norton, Arthur L., 100, William Street, New York City, U.S.A., Dyestuff Merchant.
- O.M. Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).
1911. Norton, Samuel J., Craigie Bank, 15, Merrylyce Road, Newlands, Glasgow, Engineer.
1887. Norton, Dr. T. H., c/o Wm. Bryce, 54, Lothian Street, Edinburgh, U.S. Consul.
1899. Noyes, Henry, 499-501, Bourke Street, Melbourne, Victoria, Australia, Engineer.
1901. Noyes, Prof. Wm. A., University of Illinois, Urbana, Ill., U.S.A., Editor (J. Amer. Chem. Society).
1917. Nutter-Smith, Arthur, 47, North Road, West Bridgford, Nottingham, Works Chemist (Boots Pure Drug Co.).

O

1910. Oakden, W. E., 11, Lonsdale Road, Barnes, S.W., Director of Research Laboratory.
1905. Oakes, F. J., jun., 141, Milk Street, Boston, Mass., U.S.A., Secretary, Oakes Manufacturing Co.
1904. Oberländer, Dr. Otto, 29, Queen Street, London, E.C., Research and Consulting Chemist.
1904. O'Brien, Claude H., c/o Central Cane Price Board, Dept. of Agriculture, Brisbane, North Queensland, Supervising Chemist.
1900. O'Brien, Frederick, Pineleigh, Saltford, near Bristol, Analytical Chemist.
1905. Oburg, W. F., 148, State Street, Boston, Mass., U.S.A., Assistant Treasurer (Merrimac Chem. Co.).
1917. O'Callaghan, Jas. P., c/o United Water Softeners, Ltd., Imperial House, Kingsway, London, W.C. (Journals to 36, Tyrwhitt Road, Brockley, London, S.E.), Analytical Chemist.
1908. O'Day, John, 15, Custom House Street, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.

1888. Oddy, Robert W., Abbey Street, Toad Lane, Rochdale, Chemist.
1908. Ogilvie, Jas. P., 2, St. Dunstan's Hill, E.C., Analytical Chemist.
1901. Ogston, Alex. G., Heathpark, near Aberdeen, Soap Manufacturer.
1903. Ohlenschläger, J. G., jun., Shanghai House, Botolph Lane, London, E.C., Chemical Merchant.
1905. Ohliger, Willard, c/o F. Stearns and Co., Detroit, Mich., U.S.A., Chemist.
1907. Oke, Alfred W., 32, Denmark Villas, Hove, Sussex, Solicitor.
1884. Oliver, F., 31, Horsley Hill Road, Westoe, South Shields, Analytical Chemist.
1910. Oliver, Willie, Wilton Villa, 4, St. Mary's Avenue, Carlton Grange, Batley, Yorks, Works Chemist; retain Journals.
1888. Oliver, Wm. Letts, 251, Vernon Street, Oakland, Cal., U.S.A., Mining Engineer.
1914. Olle, Arch. D., "Kareema," Charlotte Street, Ashfield, N.S.W., Australia, Electro-therapeutist.
1904. Olney, Prof. L. A., 118, Riverside Street, Lowell, Mass., U.S.A., Professor of Chemistry and Dyeing.
1916. Olssen-Seffer, R., 1, Royal Exchange Place, Calcutta, India, Nitrate Agent.
1902. O'Neill, Chas., c/o Bleachers' Association, Ltd., 4, Norfolk Street, Manchester, Chemist and Colourist.
1905. Ormandy, Dr. W. R., Imperial House, Kingsway, London, W.C., Consulting Chemist.
1898. Ormerod, Dr. Ernest, 62, Dale Street, Liverpool, Consulting and Analytical Chemist.
1894. Ormerod, John, Globe Leather Works, Castleton, Manchester, Tanner and Currier.
1913. Ormsby, Irwin, "Caleula," Allison Road, Randwick, New South Wales, Australia, Factory Assistant.
1917. Orr, Donald J. W., c/o Messrs. Orr's Zinc White, Ltd., Widnes, Lancs., Chemical Manufacturer.
- O.M. Orr, J. B., Crossacres, Woolton, Liverpool, Chemical Manufacturer.
1907. Ortvad, Niels C., c/o Hiram Walker and Sons, Ltd., Walkerville, Ont., Canada, Chemist and Fermentologist.
1900. Osbourne, Jno. P., "Bowsden," Prescott Road, St. Ann's, St. Helens, Lancs., Analytical Chemist.
1900. O'Shaughnessy, Francis R., 42, Temple Street, Birmingham, Consulting Chemist.
1885. O'Shea, Prof. L. T., Dept. of Applied Science St. George's Square, Sheffield, Professor of Applied Chemistry (University of Sheffield).
1912. Osius, George, Canadian Ammonia Co., Ltd., Foot of Meldrum Street, Detroit, Mich., U.S.A., Secretary and Treasurer.
1883. O'Sullivan, J., High Bank, Burton-on-Trent, Brewing Chemist.
1912. Oswald, Jacob, c/o Messrs. Fels and Co., 73rd Street and Woodland Avenue, Philadelphia, Pa., U.S.A., Soap Works Technical Manager.
1898. Oushkoff, John P., Warwarka 5, Moscow, Russia, Chemical Manufacturer.
1906. Oxley, Horace F., Ashfield, Helsby, Cheshire, Chemist.
1908. Oxley, John C., Oakwell House, Heckmondwike, Aniline Colour Merchant.
1886. Pagès, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.
1916. Pallister, Chas. (on Active Service; retain Journal). Metallurgical Chemist.
1906. Palm, Otto G., 41, Colborne Street, Toronto, Canada, President (Atteaux Dye and Chemical Co.).
1917. Palmberg, Dr. Bertil, Kaipainen, Finland.
1917. Palmén, Baron, Dr. J. O., Boulevardsgatan 30, Helsingfors, Finland, Research Chemist.
1903. Palmenberg, O. W., 59, Church Street, New York City, U.S.A., Consulting Chemist and Fuel Engineer.
1916. Palmer, Chas. W., Heaton House, Wilmslow Road, Withington, Manchester, Chemist.
1902. Palmer, Fred. G., c/o Curtis's and Harvey, Cliffe, Kent, Chemist and Gunetteon Superintendent.
1887. Palmer, T. Chalkley, c/o American Dyewood Co., Chester, Pa., U.S.A., Manufacturing Chemist.
1887. Palmer, Thos. C., c/o W. J. Fraser and Co., Ltd., Dagenham, Essex, Engineer.
1907. Palmer, Wm. J., 25, Beech Hill Road, Eltham, Kent, Analytical Chemist.
1915. Pandya, Prof. Kantilal, Bag Mazaffar Khan, Agra, India, Professor of Chemistry.
1911. Paniker, Ramni, Vidrio 10, Barcelona, Spain, Leather Trades Chemist.
1915. Pansky, Dr. A., c/o Williamson and Corder, Ltd., Low Walker, Newcastle-on-Tyne, Chemical Engineer.
1917. Parker, Dr. Albert, The University, Edmund Street, Birmingham, Lecturer in Chemistry.
1891. Parker, Edw., Laburnum House, Rushford Avenue, Levenshulme, Manchester, and (Jnls.) 142, Manchester Road, Denton, Manchester, Analytical Chemist.
1894. Parker, Dr. J. Gordon, Leathersellers' Technical College, 176, Tower Bridge Road, London, S.E., Principal.
1897. Parker, Prof. Matthew A., University of Manitoba, Winnipeg, Canada, Professor of Chemistry.
1915. Parker, R. G., 63, Gondar Gardens, Hampstead, N.W., Chemist.
1901. Parker, Richard H., 147, Seymour Avenue, Newark, N.J., U.S.A., Analytical Chemist.
1894. Parker, Thos. J., 100, William Street, New York City; and (Journals) Bayonne, N.J., U.S.A., Chemical Works Manager.
1903. Parker, Wm. B., 1, Murray Road, Rugby, Chief Chemist (British Thomson-Houston Co., Ltd.).
1901. Parkes, Albert E., 43, Whitehorse Street, Stepney, E., Analytical Chemist.
1915. Parrish, Percy, c/o South Metropolitan Gas Co., East Greenwich, S.E., Chemical Works Manager.
1898. Parrish, Saml., 80, Grange Avenue, Chapeltown Road, Leeds, Teacher of Chemistry.
1916. Parsons, C. H., Prior Park, and Journals to Castle Soap Works, Ashby de la Zouch, Soap Manufacturer.
1914. Pascoe, Charles F., The Thomas Davidson Manufacturing Co., Ltd., Montreal, Canada, Metallurgist.
1909. Passmore, Dr. Francis W., 81, Queen Victoria Street, London, E.C., Consulting Chemist.
1897. Patchett, Col. Jas., Oakworth, Hadley, Wellington, Salop, Ironmaster.
1884. Paterson, John, 24, Bank Street, Carlisle, Mechanical Engineer.
1916. Paton, John D., 25, Market Street, Manchester, Engineer and Technologist.
1901. Patterson, Chas. A., 1007, Broome Street, Wilmington, Del., U.S.A., Analytical Chemist.
- O.M. Patterson, Geo., Elm Lodge, 8, The Grove, Isleworth, W., Technical Chemist.
1893. Patterson, Harry J., Collage Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.
1902. Patterson, Wm. Hamilton, 30, Lightwoods Hill, Warley, Birmingham, Technical Chemist.
1917. Patterson, Wm. S., 85, Abbey Road, Barrow-in-Furness, Analytical Chemist.

- O.M. Pattison, Jas., Drimmonona, Kilmacoolm, N.B., Chemical Merchant.
1889. Pattison, Percy J., St. Budeaux, Devonshire Road, Hornechurch, Essex, Technical Chemist.
1909. Patton, H. G., c/o Fred Rueping Leather Co., Fond du Lac, Wis., U.S.A., Chemist.
1908. Paul, David M., c/o Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.
1891. Paul, Jas. H., 11, Glenluce Road, Blackheath, S.E., Analytical Chemist.
1900. Paul, Dr. L. Gordon, Market Hall Chambers, King Street, Huddersfield, Consulting Chemist.
1916. Payman, William, Home Office Experimental Station, Eskmeads, Cumberland, Chemist.
1904. Payne, A. G. C., 6, Bradford Place, Penarth, near Cardiff, Chemist.
- O.M. Payne, J. B., 13, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
1912. Peachey, S. J., 5, Yew Tree Road, Davenport, Stockport, Lecturer in Chemistry.
1894. Pearce, Jas. Stanley, Priest's Mere, Tadworth, Surrey, Chemical Manufacturer.
1897. Pearce, Richard, 6, Beach Lawn, Waterloo, Liverpool, Metallurgist.
1916. Pearce, Robert J., 318, LaGauchetiere Street West, Montreal, Canada, Analytical Chemist.
1883. Pearce, Sir W., M.P., 14, Park Crescent, Portland Place, W., Chemical Manufacturer.
1903. Pearcey, A. C., 43, Marlborough Mansions, Finchley Road, London, N.W., Director, Explosives Co.
1915. Pearson, Geo. E., c/o Burroughs, Wellcome and Co., Snow Hill Buildings, London, E.C., Chemist and General Manager.
1917. Pearson, Herbert, 4, Leinster Gardens, Runcorn, Cheshire, Technical Chemist.
1915. Pearson, Stanley, 21, Kingsway, Coventry, Works Chemist.
1904. Pease, Fred N., P.O. Box 503, Altoona, Pa., U.S.A., Chemist.
1898. Peck, Dr. Ernest L., High Lawn, Bromborough, Cheshire, Chemist.
- O.M. Pedler, Sir Alexander, C.I.E., F.R.S., 28, Stanhope Gardens, Queen's Gate, London, S.W., Director of Public Instruction (retired).
1906. Peile, Henry, Milburn House, Newcastle-on-Tyne, Colliery Owner.
1897. Pellaw, Chas. E., 111, East 78th Street, New York City, U.S.A., Adjunct Professor of Chemistry.
1904. Pelly, Russell George, 3, Wingate Road, Hammer-smith, W., Analytical Chemist.
1915. Pemberton, W. G., c/o F. Reddaway and Co., Ltd., Pendleton, Manchester (Journals to 49, Acresfield road, Pendleton, Manchester), Rubber Works Chemist.
1914. Penfold, A. R., 34, Alt Street, Ashfield, Sydney, N.S.W., Australia, Research Chemist.
1896. Penney, Mulgrave D., 11, High Street, Hull, Analytical Chemist.
1890. Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.
1885. Pentecest, S. J., Lenton Works, Nottingham, Lace Dresser.
1892. Peplow, D. H. T., Underriver House, Sevenoaks, Kent.
1885. Perkin, A. G., F.R.S., Grosvenor Lodge, Grosvenor Road, Leeds, Technical Chemist.
1898. Perkin, Dr. F. Mollwo, 59, New Oxford Street, London, W.C.
1887. Perkin, Dr. W. H., F.R.S., 5, Charlbury Road, Oxford, Professor of Chemistry.
1916. Perkins, M., 29, Whites View, Manningham, Bradford, Technical Chemist.
1917. Perkins, Stephen E., Jas. Pascall, Ltd., Furzedown Works, Streatham Lane, Mitcham, Confectioners' Manager.
1901. Perry, Chas. M., Greene, Kent County, R.I., U.S.A., Bleach and Dyeworks Chemist.
1887. Perry, David, 1, Albert Drive, Pollokshields, Glasgow, and (Journals) Forth and Clyde Chemical Works, Nitshill, near Glasgow, Manufacturing Chemist.
1917. Perry, Guy A., Lincoln House, Percy Street, Fartown, Huddersfield, Chemist.
1895. Perry, Jos. H., 276, Highland Street, Worcester, Mass., U.S.A., Teacher of Chemistry.
1903. Perry, M. J. T., Australian Drug Co., O'Connell Street, Sydney, N.S.W., Australia, Manufacturing Chemist.
1903. Perry, Robt. Swain, 31, Union Square West, New York City, U.S.A.
1911. Perry, R. W., c/o Gunn's, Ltd., Toronto, Canada, Superintendent and Chief Analyst.
1916. Perry, W. S., 65, Grafton Street, Mile End, E., Technical Chemist.
1917. Peter, Alfred M., Kentucky Agricultural Experiment Station, Lexington, Kentucky, U.S.A., Chief Chemist.
1897. Peter, D. A. H., 2508, Broadway, New York City, U.S.A., Chemist.
1908. Peters, John M., c/o National Lead Co., 111, Broadway, New York City, U.S.A., White Lead Manufacturer.
1909. Petrie, A. Swanston, c/o Gibson, Rosslyn, 154, Vicarage Road, Langley, Birmingham, Analytical Chemist.
1903. Petrie, Dr. Jas. M., The University, Sydney, N.S.W., Australia, Chemist.
1906. Pettee, Chas. L. W., c/o Hartford Laboratory Co., Hartford, Conn., U.S.A., Chemist.
1916. Pettersen, M. G., 2, Elm Grove, Hyde, Cheshire, Chief Chemist.
1892. Pettigrew, Robert, c/o Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Electro-Chemist.
1902. Pettitt, Alf., c/o Chestnut Ridge Brick Co., 7, West 45th Street, New York City, N.Y., U.S.A., Chemist.
1917. Pezzani, Henri M., c/o National Bank of South Africa, Ltd., Circus Place, London Wall, E.C., Sugar Chemist.
1916. Philbert, Pierre, French Commission of Munitions, Empire House, Kingsway, London, W.C., Leather Manufacturer.
1888. Philip, Arnold, Admiralty Chemist's Dept., H.M. Dockyard, Portsmouth, Electro-Metallurgist and Electrical Engineer.
1908. Philip, Prof. James C., Imperial College of Science and Technology, South Kensington, S.W., Professor of Physical Chemistry.
1903. Philipp, Herbert, 178, Market Street, Perth Amboy, N.J., U.S.A., Chemist and Electrochemical Engineer.
1917. Phillips, Ernest George, "Southfield," Wollaton Street, Nottingham, Electrical Engineer (Boots Pure Drug Co.).
1912. Phillips, G. A., Laboratory, The Powell Duffryn Co., Aberdare, Mon., Chemist.
1917. Phillips, George W., 52, Lendenhall Street, London, E.C., Chemical Merchant.
- O.M. Phillips, Harecourt, Court Chambers, Mawdsley Street, Bolton, Analytical Chemist.
1911. Phillips, Henry A., Royal Gunpowder Factory, Waltham Abbey, Essex, Chemist.
1917. Phillips, John T., 52, Cloncurry Street, Fulham Palace Road, Fulham, London, S.W., Chemist.
1910. Phillips, Prof. Percy P., Thomason College, Rurki, United Provinces, India, Professor of Chemistry.
1915. Phillips, Richard, St. Gatien, Warbreck Moor, Aintree, Liverpool, Chemist.
1895. Phillips, S. Chas., 47, Cannon Street, London, E.C., Chemical Engineer.
1911. Phillips, Major William E., Retain Journals.
1896. Phillips, Wm. H., 100, Milton Avenue, East Ham, E., Soap Works Chemist.
1917. Phipps, Ernest Wm., c/o Mardon, Son and Hall, Printers, Temple Gate, Bristol, Deputy Printers, Manager.
1911. Philpotts, Wilfred C., 35, Sandford Avenue, Toronto, Canada, Gasworks Chemist.
1894. Picard, Hugh F. K., 44, London Wall, London, E.C., Metallurgist.
1905. Piekard, Greenleaf W., 59, Dalton Road, Newton Center, Mass., U.S.A., Electrical Engineer.

1914. Pickard, Joseph A., 21, Rosemont Road, Acton, W., Consulting Metallurgical Chemist.
1902. Pickard, Dr. R. H., Billinge View, Blackburn, Teacher and Analyst.
1914. Pickering, Walter J., Central Laboratory, City Gasworks, Nchells, Birmingham, Works Chemist.
1914. Pickles, R. H., Prussiate Works, Droylsden, near Manchester, Chemical Manufacturer.
1915. Pickles, R. W., P. 13 W., Gretna, N.B., Pharmacist.
1915. Pickup, Edgar H., 348, Great Clowes Street, Higher Broughton, Manchester, Calico Printer.
1904. Pierce, Jas. B., jun., Lock Box 932, Charleston, W. Va., U.S.A., Chief Chemist (Rollin Chemical Co.).
1915. Pilkington, A. C., Briar's Hey, Rainhill, Lanes, Glass Manufacturer.
1888. Pilkington, G., The Conservative Club, Broad Street, Bury, Lancashire, Analytical Chemist.
1893. Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.
1894. Pilling, John E., 229, Hornby Road, Blackpool, Chemist.
1906. Pincott, Emile S., 222, St. James' Street, Montreal, Canada, Manager (Nichols Chemical Co. of Canada, Ltd.).
1914. Pinkerton, Corporal Andrew, 196250, Sect. 77, N. Coy., 4th Batt., Spec. Brigade, R.E., G.H.Q., B.E.F., France (Journals to 59, Mount Preston, Leeds), Analytical Chemist.
1910. Pinnock, Douglas R., c/o The Nucoa Butter Co., 4th Street and Avenue A, Bayonne, N.J., U.S.A., Chemist.
1905. Pinnock, H. T., 11, Fountain Road, Edgbaston, Birmingham, Chemist.
1896. Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1916. Pirrie, Noble W., Imperial Munitions Board, Union Bank Building, Ottawa, Ont., Canada, Technical Chemist.
1907. Pitman, Brig.-Gen. John, 167, Berkeley Avenue, Orange, N.J., U.S.A., U.S. Army (retired).
1902. Pittard, Jno., West Ham Chemical Works, West Ham, E., Chemical Manufacturer.
1884. Pittuck, F. W., 19, Stratford Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.
1909. Piutti, Prof. Dr. Arnaldo, Instituto Chimico-farmaceutico, R. Universita, Napoli, Italy, Director.
1899. Pizey, Jas. H., 38, Lewisham Road, Highgate Road, London, N.W., Chemist.
1915. Platt, J. H., c/o Major & Co., Ltd., Hull, Technical Chemist.
1894. Platten, Frank, c/o Elliot's Metal Co., Selly Oak Works, near Birmingham, Metallurgical Chemist.
1890. Platts, Jno. C., 547, Notre Dame, St. Lambert, Montreal, Canada, Metallurgical Chemist.
1914. Plews, George, jun., 65, Keswick Road, St. Helens, Lanes., Chemist.
1907. Poetschke, Paul, c/o L. D. Caulk Co., Milford, Del., U.S.A., Chemist.
1915. Polack, W. G., Beacon Mount, Highlands Road, Runcorn, Cheshire, Alkali Works Manager.
1901. Pollard, Wm., Oakfield, Hitchio, Herts., Chemist (retired).
1904. Pollitt, Major G. P., D.S.O., H.Q. Special Companies, R.E., B.E.F., France.
1902. Pollitt, Jas. C. T., Sharrow, The Lickey, near Bromsgrove, Worcestershire (Journals to A. A. Pollitt, Karl Cottage, Stanley Road, Knutsford) Managing Chemist.
1883. Pollock, A., Kirkland, Bonhill, Dumbartonshire, Dyeworks Manager.
1890. Pomeroy, Dr. Chas. T., 459, High Street, Newark, N.J., U.S.A., Ink Manufacturer.
1916. Pomphrey, John, c/o Sapon Ltd., and 39, Leeds Old Road, Bradford, Manager Textile Department.
1909. Pond, Dr. Francis J., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Professor of Chemistry.
1896. Pond, Prof. G. G., State College, Centre Co., Pa., U.S.A., Professor of Chemistry.
- O.M. Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.
1914. Pondal, Prof. M. Leguizamon, 726, Str. Mexico, Buenos Aires, Argentina, Doctor of Chemistry.
1906. Pont, A. Felix du, Box 31, Wilmington, Del., U.S.A., Explosives Manufacturer.
1895. Pont, Pierre S. du, c/o Dr. C. L. Reese, E. I. du Pont de Nemours Powder Co., Wilmington, Del., U.S.A., Explosives Manufacturer.
1912. Pope, Chester H., 34, Brookfield Road, Winthrop, Mass., U.S.A., Ink Manufacturer.
1899. Pope, Thos. H., 31, Cecil Street, Hillhead, Glasgow, Chemist and Lecturer on Brewing.
1900. Pope, Prof. W. J., F.R.S., University Chemical Laboratory, and (Journals) Holmesdale, Brooklands Avenue, Cambridge, Professor of Chemistry.
1917. Popham, Fredk. J. W., 71, Kennington Avenue, Bishopston, Bristol, Technical Chemist.
1912. Porritt, B. D., c/o North British Rubber Co., Ltd., Castle Mills, Edinburgh, Chief Chemist.
1911. Porteous, Jas. W., c/o Bolckow, Vaughan, and Co., Ltd., Grange Hill, Bishop Auckland, Co. Durham, Chemist and Coke Oven Manager.
1902. Porter, J. Edw., P.O. Box 785, Syracuse, N.Y., U.S.A., Chemist.
1915. Potter, Alfred, 16, Nelson Street, Lower Broughton, Manchester, Rubber Works Chemist.
1884. Potter, Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
1888. Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
- O.M. Potter, E. P., Chemical Works, Little Lever, near Bolton, Alkali Manufacturer.
1915. Potter, F. M., H.M. Factory, Penrhyn-Deudraeth, N. Wales, Chemist.
1915. Potter, H. V., 98, Bradford Street, Birmingham, Manager and Chief Chemist.
1910. Potts, Harold E., c/o W. P. Thompson and Co., 6, Lord Street, Liverpool, Patent Agent.
1915. Poulenc, Camille, 122, Boulevard St. Germain, Paris, France, Chemical Manufacturer.
1915. Powell, Alar R., 150, Capel Road, Forest Gate, Essex, Analytical Chemist.
1916. Powell, Arthur D., 152, Robin Hood Chase, Nottingham, Analytical Chemist.
1900. Powell, Harry J., 125, Thurlow Park Road, Dulwich, S.E., Glass Manufacturer.
1897. Power, Dr. Fred. B., Bureau of Chemistry, U.S. Dept. of Agriculture, Washington, D.C., U.S.A. Research Chemist.
1902. Powney, Wm. E. F., 35, Priory Avenue, Hornsey, N., Analytical Chemist.
1912. Prasad, Prof. H., Government College, Ajmer, India, Professor of Science.
1897. Prentice, Dr. Bertram, Royal Technical Institute, Salford, Lecturer on Chemistry.
1902. Prentice, Dr. David, Teesholme, Walton New Road, Lower Walton, near Warrington, Chemist.
1903. Prentice, Jas., Cossipore Sugar Works, Cossipore, Calcutta, India, Chemist.
1911. Prescott, Alfred, 63, Corporation Street, Manchester, Chemical Agent.
1900. Prescott, Prof. Saml. C., 585, Boylston Street, Boston, Mass., U.S.A., Prof. of Ind. Biology.
1916. Preston, Ernest, 105, Barker's Pool, Sheffield, Pharmaceutical Chemist and Laboratory Furnisher.
1905. Preston, Jas. F., 403, Andover Street, Lowell, Mass., U.S.A., Manufacturing Chemist.
- O.M. Price, Arthur F., 503, Market Street, San Francisco, Cal., U.S.A., Analytical Chemist.
1905. Price, Lieut. T. Slater, (R.N.V.R.), R.N.A.S. Factory, Stirling Chemical Works, Canning Road, Stratford, E. (Journals to The Technical School, Birmingham), Lecturer on Chemistry.
1904. Prichard, Norman B., 40, Quebec Street, Sherbrooke, Quebec, Canada, Superintendent.

1905. Priest, Geo. Wesley, 1018, West 10th Street, Wilmington, Del., U.S.A., General Manager.
1915. Priestley, Donald. [Address unknown.] Works Chemist.
1916. Priestley, J. W., Grove Mills, Halifax, Woollen Manufacturer.
1899. Prinsen-Geerligns, H. C., Wanningstraat 17, Amsterdam, Holland, Director of Sugar Cane Experimental Station.
1917. Pritchard, David A., "The Gables," Farnworth, Widnes, Departmental Manager.
1912. Prittie, Frank H., Southern Pacific Railway Laboratory, Sacramento, Cal., U.S.A., Assistant Chemist.
1896. Prochazka, Dr. Geo. A., c/o Central Dyestuff and Chemical Co., Newark, N.J., U.S.A., Colour Manufacturer.
- O.M. Procter, Prof. H. R., The Grange, Ilkley; and (Jnls.) The University, Leeds, Emeritus Professor of Tanning.
1884. Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
1890. Procter, Miss Ann J., Free Library, Widnes, Librarian.
- O.M. Proctor, C., 118, Grosvenor Road, London, S.W., Analytical Chemist.
1916. Pryor, J. C., 4160, Sherbrooke Street West (Flat 31), Montreal, Canada, Metallurgist and Chemist.
1917. Pugh, Frank H., 2, Cotham Street, Walworth, London, S.E., Student.
1905. Pugh, John V., Guiting House, Allesley, near Coventry, Works Director (Rudge-Whitworth, Ltd.).
1916. Pugh, Ralph J., London Chemical Works, Ltd., Southall, Middlesex (Journals to 99, Lonsdale Road, Barnes, S.W.), Director.
1899. Pullar, Edmund, Keirfield, Bridge of Allan, Scotland, Manufacturer.
- O.M. Pullar, R. D., Pullar's Dyeworks, Perth, Scotland, Dyer.
1913. Pulsifer, Lanson V., c/o Messrs. Valentine and Co., 364, Manhattan Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1902. Puntan, H. H. C., 10, London Chambers, Durban, Natal, Public Analyst.
1913. Purves, G. Thomson, Coke Ovens Dept., Auchen-geich Colliery, Chryston, Scotland, Manager.
1905. Pyman, Dr. Frank Lee, Southwood, Pinner, Chemist.

Q

1903. Queeny, Jno. F., Monsanto Chemical Works, 1800, South 2nd Street, St. Louis, Mo., U.S.A., Chemical Manufacturer.
1903. Queneau, Augustin L. J., The Chloride Syndicate, Ltd., The Quay, Wallsend-on-Tyne, Metal-lurgical Engineer.
1887. Quibell, Oliver, Shalem Lodge, Newark-on-Trent, Manure Manufacturer.
1902. Quinan, Kenneth B., Cape Explosives Works, Somerset West, C.C., South Africa, and (sub-scriptions) c/o Cape Explosives Works, Ltd., 15, St. Swithin's Lane, E.C., Superintendent.

R

1917. Rabinovitch, Dr. L., 6, Belsize Road, Hampstead, N.W., Electro-Chemical Engineer.
1911. Rae, Joseph, City Hall, Ottawa, Canada, City Bacteriologist.
1915. Radcliffe, L. Guy, 929, Chester Road, Stretford, Manchester, Chemist.
1917. Radford, Samuel C., 13, Belmont Road, Luton, Works Chemist.
1900. Radley, Ernest G., 49, Ernest Street, West Norwood, S.E.
1902. Ramsay, A. Alexander, Laboratory, Department of Agriculture, 136, George Street, Sydney, N.S.W., Australia, Assistant Chemist.

1916. Ramsay, Thos., 101, West George Street, Glasgow, Chemical Exporter.
1885. Ramsay, W., c/o Cammell, Laird, and Co., Ltd., Birkenhead Ironworks, Birkenhead, Chemist and Assayer.
1911. Ramsay, Wm. G., Beecherof, Hazlemere, Bucks., Research Chemist.
1913. Ramsbottom, Dr. J. E., 98, Peabody Road, South Farnborough, Hants, Chemist.
1906. Ranck, Samuel H., Ryerson Public Library Building, Grand Rapids, Mich., U.S.A., Librarian.
1909. Randall, George, Severn Bank Tannery, Worcester, Tanner.
1916. Randall, Jas., Low Mill, Ulverston, Lancs, Tanner.
1910. Ranken, Charles, 19, Stockton Road, Sunderland, Analytical and Consulting Chemist.
1901. Ransom, Francis, The Chilterns, Hitchin, Herts., Manufacturing Pharmaceutical Chemist.
1905. Ransom, H. B., 70, Beulah Hill, Upper Norwood, Consulting Engineer.
1898. Rasehen, Dr. Julius, The Highlands, Runcorn, Cheshire, Consulting Chemist (United Alkali Co.).
1915. Rashid, Dr. S. A., "Dar-ul-Fazl," Gujrat, Punjab, India, Pharmacist.
1908. Rassow, Prof. Dr. Berthold (address unknown), General Secretary.
1893. Ratcliff, Frank D., Stourbank House, Stourport, Vinegar Brewer.
1904. Ratcliffe, C. F., c/o Brotherton and Co., Ltd., City Chambers, Leeds, Tar Distiller.
1914. Ratcliffe, Henry, Leeds Phosphate Works, Ltd., Midland Road, Hunslet, Leeds, Chemist.
1916. Ratcliffe, Norman, 16, Park Street, Clydach, near Swansea, Analyst.
1898. Ratcliffe, Walter, c/o Carter and Wright, Hexagon Works, Pollon Lane, Halifax, Analytical Chemist.
1917. Ratcliffe, Wm. A., c/o Jas. Ratcliffe and Sons, Ltd., Hillgate Works, Stockport, Candle and Soap Maker.
1901. Rawlins, Herbert J. L., The Crossways, Rainhill, Lancashire, Managing Director.
1903. Rawolle, Frederick C., c/o Marx and Rawolle, 100, William Street, New York City, U.S.A., Chemist.
- O.M. Rawson, Chris., 22, Cumberland Street, Manchester, Consulting Chemist.
1909. Rayner, Arthur B., 45, Gilpin Avenue, East Sheen, Surrey, Chemical Broker.
1912. Rayner, Edgar A., 72, Annan Road, Gretna, near Carlisle, Analytical Chemist.
1915. Razzaek, Syed A., c/o S. A. Razzaek and Co., Charkaman, Hyderabad, Deccan, South India, Pharmaceutical Chemist.
1895. Read, E. J., c/o Pretoria Portland Cement Co., Ltd., P.O. Box 405, Pretoria, South Africa, Analyst.
1917. Read, Fredk. Wm., The Laboratory (W. D. & H. O. Wills), East Street, Bedminster, Bristol, Analytical Chemist.
1914. Read, Harold M., The Briers, North Park Avenue, Roundhay, Leeds, Manufacturing Chemist.
1913. Read, Prof. John, The University, Sydney, N.S.W., Australia, Prof. of Organic Chemistry.
1890. Reade, Thos., 118, Tettenhall Road, Wolverhampton, Manufacturing Chemist.
1908. Reavell, J. Arthur, 28, Oakwood Avenue, Becken-ham, Kent, Engineer.
1902. Redfern, C. G., 15, South Street, Finsbury, London, E.C., Patent Agent.
1915. Redfield, C. S., P.O. Box 502, Trenton, N.J., U.S.A., Rubber Chemist.
1915. Redman, L. V., Redmanol Chemical Products Co., 636, West 22nd Street, Chicago, Ill., U.S.A., Chemical Manufacturer.
1916. Redmayne, Leonard, c/o The British Engineering Co. of Russia and Siberia, Ltd., Central House, Kingsway, London, W.C., Engineer and Manager.
1914. Redpath, G. C., 10, Dean Street, Newcastle-on-Tyne, Analytical Chemist.
- O.M. Redwood, Sir Boverton, Bart., 4, Bishopsgate, London, E.C., Petroleum Expert.

1887. Redwood, Robt., 4, Bishopsgate, London, E.C., Secretary.
1886. Rée, Dr. A., 15, Mauldeth Road, Withington, Manchester, Aniline Dye Manufacturer.
1916. Reed, Arthur S., c/o J. and H. S. Pattinson, 10, Dean Street, Newcastle-on-Tyne, Analytical Chemist.
1902. Reed, Herbert C., 227-229, Fulton Street, New York City, U.S.A., Cons. Tanning Chemist.
1916. Reed, John Y., c/o Hoyle, Robson, Burnett & Co., Ltd., Bill-Quay-on-Tyne, Analytical Chemist and Works Manager.
1906. Reed, William, c/o London County and Westminster Bank, 52, East India Dock Road, Limehouse, E., Works Manager.
1893. Reekie, J. A., Buckton Grange, Stalybridge, Calico Printer's Colour Mixer.
1883. Reeks, T. H., 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.
1906. Rees, Walter J., Department of Applied Science, The University, Sheffield, Glass Works Chemist.
1900. Reese, Dr. Chas. L., Eastern Laboratory, P.O. Box 424, Chester, Pa., U.S.A., Chemist.
1915. Reeve, H. T., American Optical Co., Southbridge, Mass., U.S.A., Metallurgist.
1917. Reeves, Bartow V., The Horse Head Inn, Palmerton, Pa., U.S.A., Assistant Chief of Spelter Dept.
1916. Reeves, George, c/o British Dyes, Ltd., Dalton Works, Huddersfield, Works Chemist.
1913. Regan, Colston J., 14, Penerley Road, Catford, S.E., Analytical Chemist.
1916. Reid, Alexander F., 3, Dalmarnock Road, Glasgow, Chemist.
1897. Reid, Andrew, c/o L. and J. McLellan, 65, Port Dundas Road, Glasgow, Chemist.
1916. Reid, C. A., c/o Mauri Bros., and Thompson, 123, Castlereagh Street, Sydney, N.S.W., Technical Chemist.
1909. Reid, David E., Kodak Park, Rochester, N.Y., U.S.A., Chemist.
1906. Reid, James, Caldererux Mills, by Airdrie, Scotland, Chemist.
1905. Reid, Dr John H., Westgarth, Eccles Road, Formby, Lanes, Chemist.
1907. Reid, Robert, Agencia de Tharsis, Huelva, Spain, Analytical Chemist.
1896. Reid, Robt., Oil Mills, Horbury Bridge, near Wakefield, Chemist.
- O.M. Reid, Walter F., Fieldside, Addlestone, Surrey, Technical Chemist.
1893. Reid, Wm., jun., Bombay Dyeworks, Dadur, Bombay, India, Dyer.
1904. Reinherz, Otto. *See* Reynard, Otto.
1898. Reitmeyer, Robt. E. D., c/o Messrs. Reitmeyer, Calburn and Kindersley, Ltd., 2, Marlborough Gate, Bayswater Road, London, W., Chemical Merchant.
1916. Relyea, P. J., Dept. of Explosives Supplies, Ministry of Munitions, Storey's Gate, Westminster, S.W., Chemical Engineer.
1904. Remington, Prof. Joseph P., 1832, Pine Street, Philadelphia, Pa., U.S.A., Author, U.S. Pharmacopoeia.
1903. Remsen, Professor Ira, Johns Hopkins University, Baltimore, Md., U.S.A., Professor of Chemistry.
1911. Renaud, Paul, 8, Rue Nouvelle, Paris (9^e), France, Consulting Engineer.
- O.M. Rennie, Dr. E. H., University of Adelaide, South Australia, Professor of Chemistry.
1911. Rentschler, Mahlon J., Willoughby, Ohio, U.S.A., Chemist.
1901. Renwick, Frank F., Sunny Side, Weald Road, Brentwood, Essex, Chemist (Photographic Works).
1907. Reoch, Robert A. S., Pacific Mills Printworks, Laurence, Mass., U.S.A., Printworks Superintendent.
1894. Rettie, Dr. Theodore, 12, Ann Street, Edinburgh, Metallurgical Chemist.
1915. Reuschle, Wm. C., 471, Summer Avenue, Newark, N.J., U.S.A., Manufacturing Chemist.
1905. Revis, Cecil, 5, Carlton Villas, Station Road, Barnes, S.W., Chemist.
1904. Reynard, Otto, 3, Selborne Villas, Manningham, Bradford, Yorks, Chemist.
1916. Reynolds, Clayton W., Canadian Inspection and Testing Labs., Ltd., Montreal, Canada, Manufacturing Chemist.
- O.M. Reynolds, Dr. J. Emerson, F.R.S., 3, Inverness Gardens, Kensington, W., Professor of Chemistry.
1912. Reynolds, Wm. Colebrook, "Wharfedale," Upminster, Essex, Manufacturing Chemist.
1913. Rhead, T. F. Eric, Central Laboratory, Neehells Gas Works, Birmingham, Research Chemist.
1908. Rhoads, J. Edgar, 2211, Shallcross Avenue, Wilmington, Del., U.S.A., Leather Chemist.
1892. Rhodes, P. J., Bridge House, Church, Acerington, Dye and Print Works Manager.
1889. Richards, Edgar, 60, Ayrault Street, Newport, R.I., U.S.A., Analytical Chemist.
1888. Richardson, Dr. Clifford, Room 1615, Woolworth Building, 233, Broadway, New York City, U.S.A., Chemical Engineer.
1884. Richardson, F. W., County Analyst's Office, Bradford, Yorkshire, Analytical Chemist.
1900. Richardson, Jno. H., 29, Westbury Road, Henleaze, Bristol, Manager.
1891. Richardson, Walter W., Aldingham, Park View Crescent, Roundhay, Leeds, Manufacturing Chemist.
1903. Richardson, Wm., Linfield, Wood Lane, Headingley, Leeds, Drysalter.
1894. Richardson, Wm. H., Newsky Thread Mills, Malaja, Bolotnaja, Petrograd, Russia, Textile Chemist.
1898. Richmond, Jno. R., "Maisonette," Park Drive, Trentham, Staffs, Alkali Works Manager.
1884. Rideal, Dr. Samuel, Laboratory, 28, Victoria Street, Westminster, S.W., Consulting Chemist.
1916. Rider, Douglas, H.M. Factory, West Gorton Chemical Works, Manchester, Works Manager.
1905. Ridge, H. M., The Ridge Roasting Furnace and Engineering Co., 2, Great Winchester Street, London, E.C., Mining Engineer.
- O.M. Ridsdale, C. H., Laboratory, 3, Wilson Street, Middlesbrough, Analytical Chemist.
1899. Riederer, Emil J., Forcite Works, Landing, N.J., U.S.A., Superintendent.
1902. Riederer, Dr. Herman S., 2124, South Compton Avenue, St. Louis, Mo., U.S.A., Chemist.
1916. Rigg, Geo. F., 154, Titford Road, Langley, near Birmingham, Metallurgical Chemist.
1907. Rigg, Gilbert, c/o Associated Smelters Proprietary, Ltd., Collins House, Melbourne, Australia, Chemist.
1892. Riker, Jno. J., 19, Cedar Street, New York City, U.S.A., Merchant.
1913. Riley, George, Effra Works, South Lambeth Road, London, S.W., Chemical Engineer.
1915. Riley, Lt.-Col. J. J., 400, St. James Street, Montreal, Canada, Explosives Manufacturer.
1905. Riley, Louis J. E., 8, Newton Road, London, W., Chemist.
1912. Riley, Walter A., 100, King Street, Norwich, Brewer.
1899. Rink, Arnold, 11, Bridgewater Street, Barbican, London, E.C., Tannin Extract Manufacturer.
1889. Rintoul, Wm., "Lauriston," Ardrossan, Ayrshire, Explosives Chemist.
1901. Ripley, Philip F., 7, Abbott Street, Andover, Mass., U.S.A., Chemist.
1914. Ritchie, P. B., Box 894 G.P.O., Sydney, N.S.W., Australia, Manufacturer.
1916. Roast, Harold J., c/o The James Robertson Co., Ltd., 142, William Street, Montreal, Canada, Analyst.
1915. Roberts, Alfred A., Carlton House, Yate, Glos., Director, Strontia Works.
1907. Roberts, Chester, Swarthmore College, Swarthmore, Pa., U.S.A., Superintendent.

- O.M. Roberts, F. G. Adair, Oak Hill Lodge, Hampstead, N.W., and Jnls. to Madane Brook, c/o Messrs. A. Boake, Roberts and Co., Ltd., Carpenters' Road, Stratford, E., Chemical Manufacturer.
1916. Roberts, Frederick, Broad Oak Printworks, Broad Oak, near Acreington, Calico Printworks Manager.
1901. Roberts, H. E. U., c/o British Explosives Synd., Pitsea, Essex, Chemist.
1911. Roberts, H. W., H.M. Factory, Queensferry, near Chester, Chemist.
1916. Roberts, Joseph G., c/o Shanks and Co., Ltd., Tubal Works, Barrhead, Glasgow, Chemist.
1917. Roberts, Oswald, Chemical Dept., Inspection Dept., Royal Arsenal, Woolwich, Analytical Chemist.
1902. Roberts, Wm. H., City Analyst's Laboratory, Ashton Street, Liverpool, Analytical Chemist.
1891. Robertson, Alex. A., Riversdale, Cressington Park, Liverpool, Technical Chemist.
1916. Robertson, Arthur F., c/o National Drug and Chemical Co., Montreal, Canada (Journals to 9, Seymour Avenue, Montreal), Chemical Engineer.
1910. Robertson, Charles, c/o Messrs. S. Allsopp and Sons, Ltd., Burton-on-Trent, Brewer.
1915. Robertson, G. S., East Anglian Institute of Agriculture, Chelmsford, Essex, Agricultural Chemist.
1900. Robertson, Jas., Barneraig, South Medrox, by Glenboig, Scotland, Analytical Chemist.
1910. Robertson, Dr. Joseph G., 19, Broomhill Terrace, Partick, Glasgow, Manufacturer.
1391. Robertson, Dr. Robt., Research Dept., Royal Arsenal, Woolwich; and (Journals) 29, Charlton Road, Blackheath, S.E., Research Chemist.
1916. Robertson, W. O., The Bungalow, Redbridge, Hants., Chemist.
1910. Robertson, William, 21, Worfield Street, Battersea Park, S.W., Research Chemist.
1913. Robins, Edmund A., c/o Messrs. Kodak, Ltd., Wealdstone, Middlesex, Assistant Works Manager.
1913. Robinson, C. Stanley, H.M. Factory, Queen's Ferry, near Chester, Works Chemist.
1897. Robinson, Clarence J., 708, Jewett Avenue, West New Brighton, N.Y., U.S.A., Chemist.
1916. Robinson, Frederick, "The Hollies," Mile End, Stockport, Cheshire, Brewing Chemist.
1902. Robinson, Hy., Fishwick, Culeth Chemical Works, Newton Heath, Manchester, Manufacturing Chemist.
- O.M. Robinson, H. H., 42, Penyvern Road, Earl's Court, S.W., Analytical Chemist.
1907. Robinson, Herbert W., Robinson Bros., Ltd., Ryders Green, West Bromwich, Staffordshire, Tar Distiller.
1913. Robinson, I. H., 7, West Road, Northumberland Park, London, N., Technical Chemist.
1911. Robinson, Jas. H., 22, Park Parade, Whitley Bay, Northumberland, Analytical Chemist.
- O.M. Robinson, Jos., Farnworth, Widnes, Chemical Manufacturer.
1915. Robinson, Prof. R., Organic Chemistry Dept., The University, Liverpool, Professor of Organic Chemistry.
1916. Robinson, Robert, 36, Ripon Gardens, Newcastle-on-Tyne, Scientific Instrument Maker.
1887. Robinson, Thomas, (Journals) 401, West Street, Glasgow; and (communications), The Villa, Nitschill, Chemical Works Manager.
1902. Robitschek, Carl, 200, Worth Street, New York City, U.S.A., Scientific Brewer.
1915. Robson, J. C., 16, View Park Drive, Burnside, Glasgow, Chemist.
1915. Rocha, João, Villa Nova de Lima, Minas Gerais, Brazil, Assayer and Chemist.
1884. Rodger, Edw., 1, Clairmont Gardens, Glasgow, W.
1904. Rodger, Robert, Government Laboratory, Clement's Inn Passage, Strand, London, W.C., Chemist.
1909. Rody, Franz A., 601, West Maple Street, Johnson City, Tenn., U.S.A., Chemist.
1903. Roelofsen, Dr. J. A., c/o Coal Distillation Co., Middlesbrough, Yorks, Works Manager.
1910. Roessler, Dr. F., 89, High Street, Perth Amboy, N.J., U.S.A., Chemist.
1905. Rogers, Dr. Allen, Pratt Institute, Brooklyn, N.Y., U.S.A., Research Chemist.
1915. Rogers, Dr. F. M., c/o Standard Oil Co., Whiting, Ind., U.S.A., Chemist.
1900. Rogers, Geo. J., 32, Chudleigh Road, Brockley, S.E., Chemist.
1908. Rogers, Harry V., Ilkeston Laundry, Ilkeston, Derbyshire, Engineer.
1909. Rogers, Herbert, c/o James Lyne Hancock, Ltd., 266, Goswell Road, London, E.C., Rubber Works Chemist.
1915. Rogers, J. E., "Quarry Bank," Hawthorn Road, Bootle, Liverpool, Chemist.
1899. Rogers, John, c/o Nobel's Explosives Co., Ltd., Nobel House, Glasgow, Chemist.
1898. Roller, H. C., 493, Central Avenue, Newark, N.J., U.S.A., Superintendent.
1899. Rollin, Chas., Bylton, East Jarrow-on-Tyne, Chemical Manufacturer.
1909. Rollin, Hugh, 1558, Kanawha St., Charleston, West Va., U.S.A., Chemical Manufacturer.
- O.M. Rollin, J.C., 1, St. Nicholas Buildings, Newcastle-on-Tyne, Chemical Manufacturer.
1907. Rolph, George M., c/o California and Hawaiian Sugar Refining Co., Crockett, Cal., U.S.A., Sugar Refiner.
1905. Romanes, J. W., c/o Lothian Chemical Co., Ltd., 3, Broughton Road, Edinburgh, Chemical Engineer.
1904. Rose, Jno., Wicken House, Stretton, near Warrington, Technical Chemist.
1901. Rose, Jno. Leonard, 14, St. Vincent Road, Westcliff-on-Sea, Chemist.
1916. Rosebrugh, R. M., 120, Circle Road, Berkeley Park, Syracuse, N.Y., U.S.A., Chemical Engineer.
1897. Rosengarten, Dr. Geo. D., P.O. Box 1625, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1913. Rosenplauter, Carlos B., Seaholme, Galton Road, Westcliff-on-Sea, Petroleum Technologist.
1916. Rosenstamm, B., King Street, Perth, Western Australia, Tanner.
1893. Ross, Arthur, 1, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.
1917. Ross, John D. McB., Chemistry Dept., Imperial College of Science, S. Kensington, London, S.W., Research Chemist.
1900. Ross, Raymond, Public Analyst's Office, Burnley, Lancashire, Analytical Chemist.
1910. Ross, Thos. M., Burmah Oil Co., Yenangyat, via Myingyan, Up. Burmah, Analytical Chemist.
1910. Rossati, Guido, 226, Lafayette Street, New York City, U.S.A., Agricultural Chemist.
1911. Rossi, Dr. Carlo, 29, Via Leopardi, Milan, Italy, Electro-chemist.
1906. Rossi, Louis M., c/o General Bakelite Co., Perth Amboy, N.J., U.S.A., Works Manager.
1913. Rossini, Jas. L., 6, Firpark Terrace, Dennistoun, Glasgow, Oil Works Manager.
1906. Rossiter, E. C., Brougham, West Hagley, Worcestershire, Chemical Engineer.
1888. Rothwell, C. F. Seymour, Photographic Works, Mobberley, Cheshire, Chemist.
- O.M. Rottenburg, Dr. Paul, 55, West Regent Street, Glasgow, Chemical Merchant.
1903. Rouse, Wm., The Knowe, Carlibar Road, Barrhead, by Glasgow, Chemist.
1906. Rowell, Herbert W., Brooklands, Palinge Road, Roehdale, Analytical Chemist.
- O.M. Rowland, W. L., 2815, Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemist.
1904. Rowley, Ernest W., Chemical Laboratory, C.M.E. Department, North Eastern Railway, Darlington, Analytical Chemist.
1908. Rowley, Frank, 8, Tulnell Park Road, London, N., Metallurgist.
1901. Rowley, Walter Eugene, c/o National Aniline and Chemical Co., 100, William Street, New York City, U.S.A., Chemist.

1904. Rowling, S. R., 1, Beechwood, Kendal, Westmoreland, Chemist.
1913. Rowse, Walter W., 39, Oliver Street, Boston, Mass., U.S.A., Representative of Cassella Color Co.
1915. Roy, Dr. Charles S., 4, Farnley Road, Chingford, Essex, Chemist.
1896. Royal-Dawson, H., 155 Bradford Road, Huddersfield, Chemist.
1898. Royle, Chas. L., Hacienda Cartavio, Trujillo, Peru, Sugar Chemist.
1913. Rubinstein, I. H., *See* Robinson, I. H.
1916. Ruck, Edwin, 19, Bryn Road, Swansea, Works Manager.
1902. Rucker, Dr. Hermann von, The Windsor, Anderson Place, Buffalo, N.Y., U.S.A., Chemist.
1896. Ruddock, Fred. G., Corporation Street, Warrington, Analytical Chemist.
1895. Rudge, Alfred, United Alkali Co., Ltd., Allhusen Works, Gateshead-on-Tyne, Analytical Chemist.
1911. Rudnick, Paul, c/o Armaour and Co., Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1908. Rudolf, Prof. Norman S., Post Box 12A, Royal Automobile Club, London, S.W., Professor of Applied Chemistry.
1909. Rudolf, Dr. G., 52, Cranley Gardens, Muswell Hill, N., Manufacturing Chemist.
1884. Ruffie, Jno., Musley, Ware, Herts, Consulting Chemist and Electrician.
1898. Ruhl, Louis, c/o Roessler and Hasslacher Chemical Co., 100, William Street, and (Inls.) Box 0101, New York City, U.S.A., Chemical Merchant.
1909. Ruiloba, J. A., c/o U.S. Steel Corporation, 71, Broadway, New York City, U.S.A., Engineer.
1910. Rule, Dr. Alexander, H.M. Factory, Dean Forest, Coleford, Gloucester, Technical Manager.
1915. Rule, Dr. H. G., Chemistry Department, The University, Edinburgh, Lecturer on Chemistry.
- O.M. Rumble, C., 169, Gleneldon Road, Streatham, S.W., Chemist.
1899. Rumbold, Wm. R., Electro-metallurgist.
1913. Rumi, Dr. Tomás J., Salta 947, Buenos Aires, Argentina, Chemist.
1911. Runekles, A. R., c/o Brotherton and Co., Ltd., Lonsdale Dock, Workington, Cumberland, Technical Chemist.
1903. Runyan, Elmer G., Hutchins Building, Washington, D.C., U.S.A., Chemist and Gas Inspector.
1899. Rushby, Wm., Oakview, Batley, Yorks, Analyst.
1906. Russell, David, Rothes, Markinch, Fife, Scotland, Paper Maker.
1912. Russell, George H., c/o Michaelis, Hallenstein, and Co. Propy., Ltd., Footscray, Vic., Australia, Leather Trades Chemist.
1913. Russell, Stanley, Savonnerie Sunlight, Olten, Switzerland, Works Manager.
1912. Russell, Thomas F., 131, Steade Road, Sheffield, Analytical Chemist.
1910. Russell, William, 88, Peel House Lane, Widnes; Jnls. to c/o United Alkali Co., Pilkington-Sullivan Works, Widnes, Lancashire, Chemist.
1905. Ruttan, Prof. R. F., Medical Faculty, McGill University, Montreal, Canada, Professor of Chemistry.
1909. Ryall, W. E., 29, Darfield Avenue, Leeds, Soapworks Chemist.
1905. Ryan, Prof. F. G., c/o Parke, Davis, and Co., Detroit, Mich., U.S.A., Manufacturing Chemist.
1884. Sadtler, Dr. S. P., 210, South 13th Street, Philadelphia, Pa., U.S.A., Consulting Chemist.
1896. Sadtler, Dr. S. S., 219, South 13th Street, Philadelphia, Pa., U.S.A., Analytical and Consulting Chemist.
1897. Sage, C. Edward, 10, London Street, London, E.C., Consulting Chemist.
1902. Sahm, Louis N., c/o The Heller and Merz Co., 505, Hudson Street, New York City, U.S.A., Chemist.
1884. Salamon, A. Gordon, 1, Fenchurch Avenue, London, E.C., Consulting Chemist.
1911. Salamon, Maurice S., 79, Mark Lane, London, E.C., Consulting Analyst.
1884. Salis-Mayenfeld, Dr. E. von, 24, South Allen Street, Albany, N.Y., U.S.A., Technical Chemist.
1916. Salway, Arthur H., 59, Cavendish Drive, Rock Ferry, Cheshire, Research Chemist.
1907. Samuel, Marcus R. A., c/o Compania General de Tabacos Filipinas, 37, Fenchurch Street, London, E.C., Merchant.
- O.M. Samuel, W. Cobden, 66, Croxted Road, West Dulwich, S.E., Analytical Chemist.
1896. Samuelson, Francis A. E., Sir B. Samuelson and Co., Ltd., Middlesbrough, Ironmaster.
1916. Sanburn, J. C., Strathmore Paper Co., Mitrineague, Mass., U.S.A., Chemist.
1904. Sand, Dr. Henry J. S., Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., Lecturer and Demonstrator.
1910. Sandeman, Archibald, Ruchill Oil Works, Glasgow, Chemist.
1906. Sanders, J. McConnell, Cia Mexicana de Petrole, "El Aguila, S.A.," Tampico, Mexico, Analytical and Consulting Chemist.
1915. Sanders, W. W., Factory Library, Goodyear Tire and Rubber Co., Akron, Ohio, U.S.A., Chemist.
1895. Sanderson, John, c/o B. S. Cohen, Ltd., Neasden Lane, London, N.W., Chemist.
1890. Saniter, E. H., Stratford Villa, Moorgate, Rotherham, Analytical Chemist.
1916. Sankey, Harold, 2, Latham Road, Southport, Soap Manufacturer.
1901. Sargent, Dr. Geo. W., c/o Crucible Steel Co. of America, Oliver Building, Pittsburgh, Pa., U.S.A., Chemist and Metallurgist.
1910. Sargent, R. N., St. Albans, W. Va., U.S.A., Chemical Engineer.
1911. Sauer, J. N. A., Joh Verhulststraat 43, Amsterdam, Holland, Sugar Chemist.
1903. Saunders, Lewis E., 123, Buffalo Avenue, Niagara Falls, N.Y., U.S.A., Electro-Chemical Engineer.
1896. Saunders, Walter M., 20, Dewey Street, Olneyville, R.I., U.S.A., Analytical Chemist.
1911. Saville, W. B., 35, North Side, Clapham Common, S.W., Analytical Chemist.
1895. Sawers, Wm. D., "Woodend," Giffnock, Scotland, Chemist.
1907. Saxe, Joel B., c/o Milton Hersey Co., Ltd., P.O. Box, 1086, Montreal; Journals to c/o Milton Hersey Co., Ltd., 257, Portage Avenue, Winnipeg, Man., Canada, Chemist.
1898. Saxe, Sigmund, 111, West 78th Street, New York City, U.S.A., Manufacturing Chemist.
1890. Sayers, Jos. J., c/o H.M. Factory, Pembrey, South Wales, Explosives Chemist.
1915. Seafe, Captain R. C., Stockton Chemical Co., Stockton-on-Tees, Works Chemist.
1917. Seard, Frederic L., West India Committee, 15, Seething Lane, E.C., Consulting Chemist (Sugar).
1913. Scarfe, H. Crespin, "Chikato," Willifield Way, Hendon, N.W., Public Officer.
1899. Schaak, Dr. Milton J., 719, Victoria Street, Corona, Cal., U.S.A., Chemist.
- O.M. Schack-Sommer, Dr. G., 87, Victoria Street, London, S.W., Sugar Refiner.
1898. Schad, Dr. Philipp, *see* Shaud, Dr. Philip.
1910. Schaefer, Dr. George L., New York Quinine and Chemical Works, 105, North 11th Street, Brooklyn, N.Y., U.S.A., Chemist and Technical Manager.

1912. Schapiro, Hugo H. B., Wadsworth, Ohio, U.S.A., Chemist.
1917. Scharff, Godfrey E., 144, Warwick Road, Carlisle, Chemical Engineer.
1908. Schatzmann, Dr. Paul, Isleben bei Fluelen, Switzerland, Chemist.
1903. Scheidel, Dr. Aug., c/o Commonwealth Portland Cement Co., 4, O'Connell Street, Sydney, N.S.W., Australia, Managing Director.
1886. Schellhaas, Henry Alf., Thornhill, Beech Road, Hartford, Northwich, Mechanical Engineer.
1894. Schidrowitz, Dr. P., 57, Chancery Lane, London, W.C., Research Chemist.
1902. Schlegel, Jno. Wm., New York Sugar Refinery, Long Island City, N.Y., U.S.A., Chemist.
1893. Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Technical Chemist.
1901. Schlichting, Emil, 402 West 23rd Street, New York, City, U.S.A., Chemist.
1907. Schmitt, Charles A., The Carter's Ink Co., Cambridge "C," Boston, Mass., U.S.A., Chemist.
1904. Schniewind, Heinrich, jun., 149, Madison Avenue, New York City, U.S.A., Vice-President and Treasurer.
1904. Schoeller, Dr. Walter R., 57, York Street, Baker Street, London, W., Metallurgical and Research Chemist.
1902. Schofield, Prof. Jas. A., The University, Sydney, N.S.W., Australia, Lecturer in Chemistry.
1917. Schofield, Wilfred, 40, Grange Road, Leigh-on-Sea, Essex, Analytical Chemist.
1908. Schofield, Fred., c/o Burgess, Ledward and Co., Ltd., Dychouse Department, Walkden, Manchester, Works Chemist.
- O.M. Scholefield, H. E., Edgehill Chemical Works, Liverpool, Chemical Manufacturer.
1917. Schotz, Dr. S. P., 30, Russell Square, London, W.C., Chemist.
1906. Schroeder, C.M.E., 235 Wood Street, Rutherford, N.J., U.S.A., Analytical Chemist.
1895. Schroeder, E. August, c/o Church and Dwight Co., 1416, Willis Avenue, Syracuse, N.Y., U.S.A., Chemist.
1901. Schultz, Wm., 31, Gerry Avenue, Elmhurst, Long Island, N.Y., U.S.A., Chemist.
1907. Schwamm, Chas. A., c/o Antoine Chiris, 20, Platt Street, New York City, U.S.A., Chemist.
1889. Schweich, Emilo. See Mond, Emilo S.
1894. Schweitzer, Dr. H., Riverside Mansions, corner 113th Street and Riverside Avenue, New York City, U.S.A., Chemical Expert.
1906. Schwerin, Lorenz R., c/o Casein Co. of America, Bainbridge, N.Y., U.S.A., Vice-President.
1917. Secker, Arthur R., Portland Road, Bowdon, Cheshire, Engineer Director.
1917. Sechter, Wm. L., A4, Staff Quarters, Eastriggs Township, Annan, Analytical Chemist.
1891. Scott, Andrew L., Royal Gunpowder Factory, Waltham Abbey, Essex, Analytical Chemist.
1916. Scott, Ernest Kilburn, 51, Poplar Avenue, Edgbaston, Birmingham, Journals to Farningham, Kent, Electrochem. Engineer.
1912. Scott, Harold M., c/o R. Clay, Ltd., The Demmings, Cheadle, Cheshire, Works Chemist.
1898. Scott, Jas., Cawnpore Woollen Mills, Cawnpore, India, Chemist.
1894. Scott, Jno. Gillespie, Annislea, Clermiston Road, Corstorphine, Edinburgh, Analytical Chemist.
1912. Scott, Jno. William, 576, Church Street, Toronto, Canada.
1916. Scott, Robert, c/o Miss Cornell, 19, Ipswich Road, Stowmarket, Suffolk, Chemist.
1907. Scott, Wm. F., c/o Madison Woollen Co., Madison, Maine, U.S.A., Manager.
1904. Scoville, Wilbur L., c/o Parke, Davis, and Co., Detroit, Mich., U.S.A., Analytical Chemist.
1915. Scragg, Harold, c/o Locke, Blackett and Co., Ltd., St. Anthony's, Newcastle-on-Tyne, Analytical Chemist.
- O.M. Seudder, F., Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Chemist.
1917. Seaber, Wm. M., National Explosives Works, Hayle, Cornwall, Chemist.
1889. Searl, Albert, 7, Palmeira Avenue, Westcliff-on-Sea, Technical Chemist.
1898. Searle, Alfred B., The White Building, Fitzalan Square, Sheffield, Consulting Chemist.
1915. Seaton, Cecil, 69, Vicarage Road, Smethwick, Birmingham, Technical Chemist.
1905. Seeker, A. F., 160, Midwood Street, Brooklyn, N.Y., U.S.A., Food Analyst.
1896. Seldner, Rudolph, 383, St. John's Place, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1904. Seligman, Dr. Richard, Point Pleasant, Putney Bridge Road, Wandsworth, S.W., Chemist.
1908. Sellen, Elijah, Gasworks Laboratory, M.L.H. & P. Co., Elm Station, Montreal, Canada, Chemist.
1905. Sellers, Geo. E., Hopton Lane, Mirfield, near Huddersfield, Aniline Colour Maker.
1915. Sellers, R. A., 194, Goodshaw Lane, Crawshawbooth, Manchester, Print and Dye Works Chemist.
1898. Sen, Kavaraj Nagendra Nath, 18, Lower Chitpur Road, Calcutta, India, Physician and Chemist.
1910. Sen, Prof. Rajendra Nath, Engineering College, Sibpur, Bengal, India, Professor of Tinctorial Chemistry.
1916. Seward, Horace J., 84t, Cathedral Street, Montreal, Canada, Manufacturer.
1905. Sewell, B. F. Brooke, P.O. Box 1334, Washington, D.C., U.S.A., Chemical Engineer.
1896. Seyler, Clarence A., Public Analyst's Office, Nelson Terrace, Swansea, Chemist and Assayer.
1907. Seymour, Tom G., Kilton, Northway, Wavertree, Liverpool, Analytical Chemist.
1903. Shacklady, T. G., Hope Point, Cliffe at Hoo, Kent, Technical Chemist.
1906. Shah, Prof. S. J., Dhanasutar's Street, Ahmedabad, India, Consulting Chemist.
1916. Shankland, George A., Park Dale, Peveril Drive, Nottingham, Chemical Manufacturer. Journals to c/o Sam. Meggitt and Sons, Ltd., Sutton-in-Ashfield, Notts.
1892. Shanks, Arch., 5, Green Lodge Terrace, Greenhead, Glasgow, Chemist.
1908. Shanks, John, Dalmeny Park, Barrhead near Glasgow, Sanitary Engineer.
1908. Shard, Dr. Philip, The Gables, Hartford, Cheshire, Manufacturing Chemist.
1916. Sharp, F. L., 4, Rushworth Avenue, West Bridgford, Nottingham; Journals to c/o Sam Meggitt & Sons, Ltd., Sutton in Ashfield Notts.
1916. Sharpe, Frederick H., Reba Villa, Rowlands Gill, co. Durham, Chemist.
1901. Sharples, G. H., 253, Onslow Drive, Glasgow, Works Chemist.
1905. Sharples, Philip P., 90, Porter Place, Montclair, N.J., U.S.A., President (Nat'l. Coal Tar Co.).
1884. Sharples, Stephen P., 22, Concord Avenue, Cambridge, Mass., U.S.A., Analytical Chemist.
1911. Shaverock, Charles W., 35, Great St. Helen's, E.C., Cement Manufacturer.
1900. Sharwood, Dr. Wm. J., c/o Homestake Mining Co., Lead, South Dakota, U.S.A., Metallurgical Chemist.
1900. Shattuck, A. F., c/o Solvay Process Co., Detroit, Mich., U.S.A., Chemist.
1915. Shaw, John H., Public Library, Bury, Lancashire, Librarian.
1913. Shaw, T. W. A., "Springfield," Dee View Road, Heswall, Cheshire, Process Manager.
1912. Shearman, Cecil H., The Tees Bone Mills, Thornaby-on-Tees, Managing Director.
1904. Shedden, Frank, 25, Middleborough Road, Coventry, Science Master.
1903. Sheldon, Dr. N. L., Cordite Factory, Aruvankadu, Nilgiri Hills, India, Works Manager.
1912. Shelley, F. E., Apothecaries' Hall, Blackfriars, London, E.C., Analytical Chemist.

1912. Shelley, Wm. E., 20, Mount Street, Manchester, Engineer.
1911. Shelton, James, Government Laboratories, Singapore, S.S., Chemist.
1913. Shengle, J. C., c/o Major Bros., Ltd., Kiangsu Chemical Works, Shanghai, China, General Manager.
1892. Shenton, Jas. P., 37, Torbay Road, Chorlton-cum-Hardy, near Manchester, Analytical Chemist.
1916. Shenton, Joseph C., c/o Newcastle Alloy Co., Ltd., Rowlands Gill, co. Durham, Metallurgical Chemist.
1906. Shepard, Jas. H., Experiment Station, Brookings, S. Dakota, U.S.A., Agricultural Chemist.
1907. Shephard, Fred. G., Hetland Cottage, Ruthwell, Dumfriesshire, Chemist. Ret'n Journ ls
1904. Shephard, A. B., Copenhagen Oil Mills, Limehouse, London, E., Analytical Chemist.
1917. Shepherd, Harry, 17, Maudsley Street, Bury, Lancs, Works Chemist.
1893. Shepherd, H. H. B., 8, The Park, Sidenup, Kent, Chemist.
1898. Shepherd, Reginald des F., Central Laboratory, Rhodes, Manchester, Printworks Chemist.
1909. Shephard, Stephen W., c/o Eastern Chemical Co., Ltd., Rowles Hill, Dharavi, Bombay, India, Works Manager.
1899. Shero, John E., c/o Aluminium Co. of America, Niagara Falls, N.Y., U.S.A., Chemist.
1893. Shields, Dr. John, Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.
1896. Shimomura, Prof. K. Shinkarasumaru, Kojinguchi, Kyoto, Japan. Professor of Chemistry.
1905. Shoffstall, Arthur S., 153, Henderson Avenue, New Brighton, Staten Is., N.Y., U.S.A., Chemist.
1899. Sholes, Chas. E., 80, Maiden Lane, New York City, U.S.A., Chemical Agent.
1900. Shonk, Albert, 9, Lambton Road, Cottenham Park, Wimbledon, Analytical Chemist.
1897. Shores, Dr. Jeff. H., Kingsway, Frodsham, Cheshire, Chemist.
1904. Short, Andrew, 23, Hotspur Street, Tynemouth, Northumberland, Works Chemist.
1902. Shoubridge, Sydney Y., Gasworks, Lower Sydenham, S.E., Gas Engineer.
1901. Shukoff, Dr. Alexis A., Borowaja No. 86, Petrograd, Russia, Technical Chemist.
1915. Shulman, Harry, 21, Tredegar Square, Bow, E., Analytical Chemist.
1916. Shulman, Isaac, 75, Reginald Terrace, Chapeltown, Leeds, Yorks, Colour Chemist.
1890. Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, Agricultural Chemist.
1906. Shuttleworth, E. B., 220, Sherbourne Street, Toronto, Canada, Chemist.
1901. Siau, Raymond L., Springfield Brewery, Wolverhampton, Research Chemist.
1902. Sibley, Samuel E., c/o Mauri Bros. and Thomson Ltd., 123, Castlereagh Street, Sydney, N.S.W., Australia, Technical Chemist.
1912. Siddons-Wilson, S., 4, Northfield Road, East Ham, E., Analytical Chemist.
1915. Siderfin, N. E., c/o The Gas Light and Coke Co., Tar and Liquor Works, Beckton, E., Works Chemist.
1902. Siebold, Alfred, c/o Lactose Ltd., Hibernia Works, Tipperary, Ireland, Technical Chemist.
1901. Silberrad, Dr. Oswald, Sunny Croft, Buckhurst Hill, Essex, Research Chemist.
1912. Sillars, Daniel, The Laboratory, Bolekow, Vaughan, and Co., Ltd., South Bank, S.O., Yorks, Metallurgical Chemist.
1892. Silvester, Harry, 78, Holyhead Road, Handsworth, Birmingham, Analytical and Consulting Chemist.
1901. Sim, Wilfrid A., c/o Wm. Sim and Sons, 40, Jane Street, Leith, Scotland, Colour Manufacturer.
1911. Simmons, Thos. A., "Shaugh," 6 Albert Road, Caversham, Reading, Technical Chemist.
1903. Simmons, Wm. H., Oakleigh, Stoke Newington Common, N., Analytical Chemist.
1898. Simon, Dr. A., 80, Bishopsgate, London, E.C., Chemical Engineer.
1905. Simons, Albert J., Pontianak, Dutch West Borneo, vii Singapore, Engineer.
1902. Simonson, Wm., 126, West 9th Street, Cincinnati, Ohio, U.S.A., Chemist.
1905. Simpson, Henry, 26, Austen Avenue, Sherwood Rise, Nottingham, Works Chemical Assistant.
- O.M. Simpson, W.S., Wyndcroft, Old Park Road, Enfield, N., Analytical Chemist.
1900. Sims, W. Edgar, Colinswell House, Burntisland, Fifeshire, Manager (British Aluminium Co.)
1894. Sinclair, Dr. W., 250, Ferry Road, Leith, Scotland, Chemist.
1890. Sindall, R. W., 2, Oxford Court, Cannon Street, London, E.C., Paper Chemist.
1911. Singh, Shersingh W., N.W. Railway, Beas, Punjab, India, Engineer.
1899. Singmaster, J. Arthur, 10, Millard Avenue, Bronxville Terrace, Yonkers, New York, U.S.A., Chemist.
1901. Sinnatt, Frank S., 321, Great Clowes Street, Higher Broughton, Manchester, Demonstrator of Chemistry.
1916. Sisson, Geo., Junr., Elvaston Road, Hexham, Consulting Chemist.
1917. Sissons, Harold H., c/o Sissons Bros., and Co., Ltd., Hull, Varnish, etc., Manufacturer.
1914. Sjöhlahl, H.A., c/o The Chatfield Manufacturing Co., Station P., Cincinnati, Ohio, U.S.A., Chemist.
1912. Skellon, Herbert, Newlands, Water Street, Leyland, near Preston, Chemist.
1894. Skelton, John R., c/o Norwich Crape Co. (1856), Ltd., St. Augustine's, Norwich, Managing Director.
1897. Skertchly, W. P., "Kenwyn," Station Road, Barrowash, near Derby, Analytical Chemist.
1891. Skilton, C. F. E., c/o Beamish and Crawford, Ltd., Cork, Ireland, Brewer.
1901. Skinner, Hervey J., 71, West Chestnut Street, Wakefield, Mass., U.S.A., Chemist.
1908. Skinner, Wm., 38, Sanchiehall Street, Glasgow, Analytical Chemist.
1917. Skipp, Ralph W., 10, Clarendon Road, Leeds, Student of Technical Chemistry.
1904. Skirrow, Dr. F. W., Macdonald Chemistry Building, McGill University, Montreal, Canada, Assistant Professor of Chemistry.
1911. Skjold, E., Erith Oil Works, Erith, Kent, Technical Manager and Chemist.
1904. Skowronski, S., c/o Raritan Copper Works, Perth Amboy, N.J., U.S.A., Chemist.
1891. Skurray, Thos., The Brewery, 40, Ock Street, Abingdon, Berks, Brewer.
1917. Slack, Harry, 59, Great Egerton Street, Stockport, Chemist.
1917. Slann, Alfred E. L., 31, Ranelagh Gardens, Stamford Brook Avenue, London, W., Works Chemist.
1904. Slater, Dr. Arthur, 174, Ashby Road, Burton-on-Trent, Lecturer and Demonstrator.
1912. Slattery, F. J., 31, Morningson Avenue, Cranbrook Park, Ilford, E., Analytical Chemist.
1906. Sleeper, Robt. R., 112, Charles Street, Lowell, Mass., U.S.A., Instructor in Dyeing.
1916. Sloan, Alexander, P.O. Box 410, Cumberland, Md., U.S.A., Manufacturing Chemist.
1895. Slocum, Dr. Frank L., 401, South Linden Avenue, E.E., Pittsburg, Pa., U.S.A., Chemist.
1913. Slusser, Holland B., c/o Hodgman Rubber Co., Tuckahoe, N.Y., U.S.A., Chief Chemist.
1898. Small, Fritz H., 38, Berwick Street, Worcester, Mass., U.S.A., Chemist.
1915. Smalley, Oliver, 7, Wentworth Place, Newcastle-on-Tyne, Metallurgist.
1904. Smart, Bertram J., Testing Branch, Dept. of Public Works, Sydney, N.S.W., Australia, Chemist.
- O.M. Smetham, A., 16, Brunswick Street, Liverpool, Analytical Chemist.
1916. Smith, Albert E., c/o New Bedford and Agawam Finishing Co., East Warcham, Mass., U.S.A., Bleaching Agent.

1905. Smith, Prof. Albert W., Case Library, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1916. Smith, Alfred, Excelsior Works, Clayton, Manchester, Chemical Manufacturer.
1898. Smith, Alf. B., Ryecroft, Glossop, Derbyshire, Bleacher and Dyers' Manager.
1897. Smith, Allan, 30, Fountainhall Road, Edinburgh, Chemist.
1914. Smith, Andrew, c/o Leech, Neal, and Co., Ltd., Spondon, Derby, Colour Manufacturer.
1896. Smith, Andrew T., c/o Castner-Kellner Alkali Co., Ltd., 257, Royal Liver Building, Liverpool, General Manager.
1905. Smith, Arthur, Town End Chemical Works, Bramley, Leeds, Chemical Manufacturer.
1912. Smith, 2nd Lieut. Arthur R., O.W.A., B.E.F. (Journals c/o Professor H. L. Smith, 17, Bloomsbury Square, W.C.), Chemist.
1916. Smith, Claude, Barnburgh, Carmel, Grange-over-Sands, Lancs, Chemist.
1893. Smith, Edgar B., c/o Dominion Tar and Chemical Co., Ltd., Box 415, Sault Saint Marie, Ontario, Canada, Manager.
1913. Smith, Edward C., 18, Constance Street, and c/o Canadian National Carbon Co., 99, Paton Road, Toronto, Canada, Superintendent.
1906. Smith, E. A. Cappelen, c/o M. Guggenheim's Sons, 120, Broadway, New York City, U.S.A., Metallurgical Engineer.
1895. Smith, Dr. E. Ellsworth, Suite 80, Chemists' Building, 50, East 41st Street, New York City, U.S.A., Consulting Physiological Chemist.
1892. Smith, Ernest A., The Assay Office, Leopold Street, Sheffield, Assayer.
1911. Smith, E. Woodhouse, Central Laboratory, City Gasworks, Neebells, Birmingham, Chief Chemist.
1891. Smith, Francis P., 131-133, East 23rd Street, New York City, U.S.A., Chemist.
1907. Smith, Frank Morse, 81, Fulton Street, New York City, U.S.A., Chemical Merchant.
1908. Smith, George A., 1433, President Street, Brooklyn, N.Y., U.S.A., Chemist (Printing Ink).
1907. Smith, George D., 247, Atlantic Avenue, Boston, Mass., U.S.A., Salesman.
1916. Smith, Harold P., 5, North View, Whickham, Works Chemist.
1890. Smith, Harry E., 105, Mamaroneck Avenue, White Plains, N.Y., U.S.A., Analytical Chemist.
1904. Smith, Henry, 83, Brownlow Road, Horwich, Bolton-le-Moors, Lancs, Analytical Chemist.
1902. Smith, Hy. Geo., Technological Museum, Harris Street, Ultimo, Sydney, N.S.W., Australia, Assistant Curator and Chemist.
- O.M. Smith, Henry R., 1, Aubert Park, Highbury, London, N., Analytical Chemist.
1915. Smith, Herbert, "Rose Bank," Old Chester Road, Woodhey, Rock Ferry, Cheshire, Works Chemist.
1905. Smith, H. Melville, Ammunition Works, Abbey Wood, Kent, Engineer.
1901. Smith, H. Procter, Highfield, Shotton Lane, Shotton, Flintshire, Metallurgical Chemist.
1905. Smith, Hugh Duntord, 7 and 9, The Side, Newcastle-on-Tyne, Analytical Chemist.
1906. Smith, Irwin J., 21, Lyon Avenue, Menands, Albany Co., N.Y., U.S.A., Salesman.
- O.M. Smith, Jas., Ash Grove House, Radcliffe, Manchester.
1897. Smith, James, Sunnyside, Groes Road, Cressington, near Liverpool, Analytical Chemist.
1903. Smith, James, "Lyndhurst," Frodsham, and (Jnls.) Ditton Copper Works, Widnes, Metallurgist.
1907. Smith, Jas. C., c/o Edward Ripley and Son, Ltd., Bowling Dyeworks, Bradford, Dyer.
1893. Smith, Jas. F., Central Laboratories, Gas Works, Neebells, Birmingham, Analytical Chemist.
1901. Smith, J. Cruickshank, King's House, King Street, London, E.C., Technical Chemist.
1888. Smith, J. Tertius, Richmond House, Plaistow, Essex, Technical Chemist.
- O.M. Smith, Jno. W., 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A., Analytical Chemist.
1890. Smith, J. Wm., 1615, West Genesee Street, Syracuse, N.Y., U.S.A., Alkali Works Manager.
1916. Smith, Julian C., c/o Shawinigan Water and Power Co., 611, Power Building, Montreal, Canada, Chief Engineer.
1911. Smith, N. Garrett, Heathside, Treville Street, Rochampton, S.W., Analytical Chemist.
1898. Smith, R. F. Wood, 90, Lower Thames Street, London, E.C., Consulting Chemist. On Active Service.
1890. Smith, Dr. R. Greig, Linnean Society's House, Elizabeth Bay, Sydney, N.S.W., Bacteriologist and Chemist.
1890. Smith, Robert Watson, c/o The New Transvaal Chemical Co., Ltd., Delmore, Transvaal, South Africa, Chemical Works Manager.
1916. Smith, Samuel G., Tattenhall Road Works, near Chester, Fat, Glue, and Manure Manufacturer.
1914. Smith, Stanley, The Ammonia Soda Co., Ltd., Lostock Gralam, near Northwich, Chemist.
1907. Smith, Thorn, 49, West Larned Street, Detroit, Mich., U.S.A., Chemist.
1910. Smith, Vincent, J., 107, Swinderby Road, Wembley, Middlesex, Technical Chemist.
1903. Smith, Dr. Warren R., Lewis Institute, Chicago, Ill., U.S.A., Teacher.
- O.M. Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Retired Editor and Chemist.
1908. Smith, Dr. Watson, jun., Cape Explosives Works, Somerset West, C.C., South Africa, Chemist.
- O.M. Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.
1910. Smith, W. C., c/o The Anchor Cable Co., Leigh, Lancashire, Analytical Chemist.
1909. Smith, Wm. G., 23, Wickham Way, Park Langley, Beckenham, Kent, Chemical Merchant.
1916. Smith, Wm. Stanley, Tattenhall Road Works, near Chester, Fat, Glue, and Manure Manufacturer.
- O.M. Smithells, (Lt.-Col.) A., F.R.S., G.H.Q. Home Forces, Horse Guards, London, S.W., Professor of Chemistry.
1902. Smoot, Albert M., 99, John Street, New York City, U.S.A., Analytical Chemist.
1909. Smoot, Chas. C. III., c/o C. C. Smoot and Sons Co., North Wilkesboro', N.C., U.S.A., Tanning Chemist.
1888. Snape, Dr. H. Lloyd, Balholm, Lathom Road, Southport, Director of Education for Lancashire.
1908. Snell, Professor John F., Macdonald College P.O., Prov. Quebec, Canada, Professor of Chemistry.
1915. Snowber, John L., 3671, Broadway, New York City, U.S.A., Manufacturing Chemist.
1896. Snowden, J., Messrs. Snowden, Sons and Co., Millwall, E., Chemical and Oil Manufacturer.
1894. Soane, Chas. E., 31, Mattison Road, Hornsey, N., Analyst.
1903. Sohlman, Ragnar, Bofors, Sweden, Manager (A. B. Bofors Nobelkrut).
1894. Sohn, Chas. E. See Soane, Chas. E.
1906. Solomon, M., Birmingham Carbon Works, Witton, Birmingham, Manager.
1916. Solomon, Simon, 22, Sainfoin Road, Upper Tooting, S.W., Works Chemist and Manager.
1914. Somerville, C. Winthorpe, South Metropolitan Gas Company, East Greenwich, S.E., Works Chemist.
1884. Sommer, Adolph, Corner 1st and Binney Streets East, Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
1907. Sonsthagen, Asbjörn, 35, Drayton Grove, W., Ealing, London, W., Engineer, Chocolate Trade.
1912. Sorley, Jas., Novara, Mount Vernon, Glasgow, Analytical Chemist.
1904. Southall, A. W., Lower Priory, Birmingham, Manufacturing Chemist.
1904. Southarden, F., 11, Gordon Road, Exeter, Teacher of Chemistry.
1890. Sowerby, Thos. H., Canal Soap Works, Verney Road, Rotherhithe, S.E., Soap Manufacturer.
1887. Spackman, Chas., Rosehaugh, Clitheroe, Lancashire Portland Cement Manufacturer.

1910. Spackman, Henry S., 2211, Chestnut Street, Philadelphia, Pa., U.S.A., President of Engineering Co.
1904. Sparre, Fin, c/o E. I. du Pont de Nemours and Co. Room 250, du Pont Building, Wilmington, Del., U.S.A., Director.
1913. Speedy, Alan, 81, Burges Road, East Ham, E.6, Technical Chemist.
1904. Speiden, C. C., 46, Cliff Street, New York City, U.S.A., Chemical Merchant.
1905. Speight, W. E., Haeken Sewage Works, Great Lever, Bolton. Chemist.
1911. Spence, Dr. David, Norwalk, Conn., U.S.A., Research Chemist.
1900. Spence, Howard, Journals to Manchester Alum Works, Manchester, Chemical Manufacturer.
1883. Spence, Jno. W., Tiviot Colour Works, Manchester Road, Stockport, Drysalter.
1903. Spencer, A. Gordon, 4076, Tupper Street, Westmount, P.Q., Canada, Chemist.
1917. Spencer, Edward J., 212, Hulme Hall Lane, Miles Platting, Manchester, Chemical Engineer.
1903. Spichmann, Dr. P. E., c/o The Institute of Chemistry, 30, Russell Square, London, W.C., Chemist.
1906. Spiera, Dr. V. G., c/o Inchiostroificio-Veneto, Treviso, Italy, Chemist.
1889. Spies, Adolph, 21, Broadwater Down, Tunbridge Wells, Chemical Merchant.
1885. Spiller, A., 20, Holly Avenue, Newcastle-on-Tyne, Electrician.
- O.M. Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
1914. Spilman, G. H., 3, Park Place, Maze Hill, London, S.E., Works Chemist.
1896. Spoor, J. L., Rede Court, Rochester, Kent, Portland Cement Manufacturer.
- O.M. Squire P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
1916. Srivastava, J. P., Department of Industries for United Provinces, Cawnpore, India, Technical Chemist.
- O.M. Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburgh, Pa., U.S.A., Consulting Chemist.
1912. Stancourt, Fred., 24, Walbrook, London, E.C., Chemical Manufacturer.
1904. Standfast, Jno. T., Prince Regent's Wharf, Silver-town, E., Chemist.
1917. Stanhill, David B., Research Dept., Levinstein, Ltd., Blackley, Manchester, Chemist.
1897. Stannard, Dr. Oscar J., c/o Twite and Stannard, 65, London Wall, E.C., Consulting Metallurgist.
1888. Stantial, Frank G., c/o Cochrane Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
1885. Staples, H. J., The Old Hall, Spondon, Derby, Colour Manufacturer.
- O.M. Stark, J. F., Rosedale, Bromborough, Cheshire, Works Manager.
1917. Starnes, Arthur H., c/o Pirie's Photographic Paper Co., Ltd., Waterton Works, Aberdeenshire, Manager.
1916. Starrels, Joel, 250, Front Street, New York City, U.S.A., Chemical Engineer.
1896. Statham, Neel, c/o West Virginia Pulp and Paper Co., 200, Fifth Avenue, New York City, U.S.A., Engineer.
1907. Stand, Joseph E., c/o W. W. Lawrence and Co., West Carson Street, S.S., Pittsburgh, Pa., U.S.A., Chemist.
1904. Stauffer, W., 64, Oberwilerstrasse, Basle, Switzerland, Chemical Works Manager.
1895. Stead, J. Christopher, 57, Chancery Lane, London, W.C., Technical Chemist.
- O.M. Stead, Dr. J. E., F.R.S., 11, Queen's Terrace, Middlesbrough-on-Tees, Analytical Chemist.
1915. Steedman, Geo., Annickburn, Irvine, Ayrshire, Chemical Manufacturer.
1896. Steel, Fred. W., c/o General Chemical Co., Ltd., Auburn, Sydney, Australia, Works Manager.
- O.M. Steel, Thos., Colonial Sugar Refining Co., O'Connell Street, Sydney, N.S.W., Australia, Sugar Chemist.
1914. Steele, George Francis, c/o Canadian Export Paper Co., Ltd., Sun Life Building, Dominion Square, Montreal, Canada, Paper Manufacturer.
1915. Steger, Prof. Alph. M.A.A., Bibliotheek van het Schiekundig Laboratorium der Technische Hoogeschool, Delft, Holland, Chemical Technologist.
1912. Steiner, Bernard C., Enoch Pratt Free Library, Baltimore, Md., U.S.A., Librarian.
1897. Steinhart, Dr. Oscar J., See Stannard, Dr. Oscar J.
1912. Steinhoff, Fred., See Stancourt, Fred.
1887. Stenhouse, T., 166, Drake Street, Rochdale, Analytical Chemist.
1908. Stenhouse, Thos., jun., Chemical Laboratory, H.M. Dockyard, Portsmouth, Analytical Chemist.
1904. Stephen, A. E., 67, Castlereagh Street, Sydney, N.S.W., Australia, Analytical Chemist.
1917. Stephens, Albert J., c/o John Stephens, Son and Co., Ltd., Gloucester, Jam and Vinegar Manufacturer.
1911. Stephens, C. E., Messrs. Stephens Bros. & Co., 2, Bury Court, St. Mary Axe, E.C., Chemical Merchant.
1884. Stephens, H. Chas., Avenue House, Finchley, N., Ink Manufacturer.
1892. Stephens, M. E., 57-60, Aldersgate Street, London, E.C., Ink Manufacturer.
1917. Stephens, Thos. E., c/o The Russian American Indian Rubber Co., Treugolnik, Petrograd, Russia, Chemist and Manager.
1909. Stephenson, Henry H., 52, Commercial Road, Hayle, Cornwall, Technical Chemist.
1909. Stephenson, Herbert F., 8, The Park, Mitcham, Surrey, Analytical Chemist.
1889. Stern, Arthur L., 148, High Street, Burton-on-Trent, Brewing Chemist.
1912. Sterne, Edward T., Imperial Munitions Board, Beloeil Station, Quebec, Canada, Chemist.
- O.M. Steuart, D. R., Osborne Cottage, Broxburn, West Lothian, Oilworks Chemist.
1903. Steven, A. B., Royal Technical College, Glasgow, Lecturer on Dyeing.
1914. Steven, George, 23, Denstone Road, Pendleton, Manchester, Pharmaceutical Chemist.
1907. Steven, Michael M., c/o The Murree Brewery Co., Ltd., Rawalpindi, Punjab, India, Analytical Chemist.
1899. Stevenot, G. A., 280, Baltic Street, Brooklyn, N.Y., U.S.A., Chemist.
1902. Stevens, Dr. Hy. P., Laboratory, 15, Borough, London Bridge, S.E., Consulting Chemist.
1894. Stevens, Jno. H., c/o Librarian, The Celluloid Co., 3, Westcott Street, Newark, N.J., U.S.A., Manufacturing Chemist.
1908. Stevens, J. Venn, 30, Linthorpe Road, Stamford Hill, London, N., Analytical Chemist.
1916. Stevens, Victor G., 6, Kingland, Jesmond, Newcastle-on-Tyne, Metallurgist.
1917. Stevenson, Alex. W., 5, Chiswick Street, Carlisle, Chemist.
1917. Stevensen, Arnold, 4, Porchester Gardens, London, W., Chemist.
1916. Stevenson, C. E., Inglis Green House, Slateford, Midlothian, Dyer and Manufacturer.
1917. Stevenson, Capt. R., Inspector Ordnance Machinery, A.O.D. O i/c Heavy Mobile Workshop, A.P.O. S 14, Third Army, France, Consulting Engineer.
- O.M. Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.
1913. Steward, H. Bernard, Rose Hill House, Coseley, near Bilston, Staffs, Enamel Chemist.
1912. Stewart, Allan E., 136, Bedford Road, Toronto, Canada, Chemist.
1901. Stewart, David B. D., Aberdeen Comb Works, Hutcheon Street, Aberdeen, Managing Director.
1903. Stewart, Jas., "The Gas World," 8, Bouverie Street, Fleet Street, London, E.C., Editor.
1909. Stewart, Jeffrey, c/o E. F. Drew Inc., McKean and Swanson Streets, Philadelphia, Pa., U.S.A., Works Manager.
1890. Stewart, Robt., 46, Westbourne Road, Luton, Chemical Works Manager.

1916. Stewart, Robert P., 402 Lakeview Aven., Jamestown, N.Y., U.S.A., Dyer, Empire Worsted Mills.
1915. Stewart, R. P., Carricklea, Kirkintilloch, Scotland, Analytical and Manufacturing Chemist.
- O.M. Stewart, S., c/o Michael Nairn and Co., Ltd., Kirkealdy, Fife, Technical Chemist.
1906. Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Chemist.
1904. Stieglitz, Dr. Julius, University of Chicago, Chicago, Ill., U.S.A., Associate Professor of Chemistry.
1904. Stiff, John T., 37, Grasmere Road, Handsworth, Birmingham, Works Chemist.
1903. Stillwell, Albert G., 76½, Pine Street, New York City, U.S.A., Chemist.
1917. Stobart, James W., 37, Cicada Road, Wandsworth Common, S.W., Chemist.
1916. Stobart, Wm. R., Etherley Lodge, Bishop Auckland, Managing Director, H. Stobart and Co., Ltd.
1914. Stock, Cyril J. H., 9, Houndgate, Darlington, Analytical Chemist.
1900. Stockdale, Edgar, c/o R. Dewhurst and Co., Ltd., Printworks, Batley, Yorks, Colour Mixer.
1888. Stockdale, Wm., Rosebank Printworks, Ramabottom, near Manchester, Calico Printer.
1887. Stocks, H. B., 33, Prenton Park Road, Birkenhead, Cheshire, Analytical Chemist.
1916. Stockton-Abbott, Lyle, 300, Willow Avenue, River Edge, N.J., U.S.A., Chemical Engineer.
1903. Stoddard, Jesse D., 674, Woodward Avenue, Detroit, Mich., U.S.A.
1899. Stokes, Alf. W., Laboratory, Town Hall, Paddington Green, W., Public Analyst.
1910. Stokes, Colonel Edward S., 18, Ben Boyd Road, Neutral Bay, Sydney, N.S.W., Australia, Medical Officer.
1900. Stone, Geo. C., c/o New Jersey Zinc Co., 55, Wall Street, New York City, U.S.A., Engineer.
1899. Stone, I. F., 100, William Street, New York City, U.S.A., Chemical Merchant.
- O.M. Storey, I. H., Haverheskas, Lancaster, Chemical Manufacturer.
1914. Storie, George B., 62, Vineyard Hill Road, Wimbledon, S.W., Works Manager.
1902. Storr, Bertram V., 26, The Square, Garden Suburb, Ilford, Essex, Chemist.
1914. Stott, Augustus P., 165, City Road, N., Manager.
1909. Strachan, Jas. T., c/o The Canada Paper Co., Ltd., Windsor Mills, P.Q., Canada, Technical Chemist.
1916. Strafford, Norman, 95, Tonbridge Street, Leeds, Chemist.
1917. Street, Brooks K. G., 10, Tutton Grove, Withington, Manchester, Analytical Chemist.
1903. Strickler, Emerson H., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemist.
1909. Strivens, Percy R., 20, Cartmel Road, St. Annes-on-Sea, Lancs, Analytical Chemist.
1916. Stuart, A. T., Toronto Power Co., 12, Adelaide Street East, Toronto, Canada, Chemical Engineer.
1896. Stuart, Harry T. R., High Bank, Walshaw, Bury, Lancs, Manager.
- O.M. Stuart, T. W., 7, Livingston Drive, Sefton Park, Liverpool, Alkali Works Manager.
1896. Stubbs, Augustus J., Castellon de la Plana, Spain.
1903. Sturrock, Major G. C., R.A., 6, Esplanade East, Calcutta, Deputy Director of Ordnance Factories, India.
1908. Suart, Arthur B., c/o Johnson and Sons' Smelting Works, Ltd., Paul Street, Finsbury, London, E.C., Bullion Refiner.
1895. Sudborough, Dr. J. J., Indian Institute of Science, Bangalore, India, Lecturer in Chemistry.
1916. Sullivan, E. C., Corning Glass Works, Corning, N.Y., U.S.A., Chemist.
1889. Sulman, H. L., 44, London Wall, London, E.C., Chemist and Metallurgist.
1910. Sulzer, Albert F., 16, Beverly Street, Rochester, N.Y., U.S.A., Chemical Engineer.
1907. Sundar-Ram, Minakshi, c/o Parry and Co., Ranipettai, N. Arcot, Madras, India, Agricultural Chemist.
1912. Sutchliffe, J. A. L., c/o Price's Co., Ltd., Belvedere, Kent, Analytical Chemist.
1906. Sutermeister, Edwin, c/o S. D. Warren and Co., Cumberland Mills, Westbrook, Maine, U.S.A., Chemist.
1884. Sutherland, D. A., 26, Victoria Street, Westminster, S.W., and (Jnls.) Fairfield Lodge, Twickenham, Consulting Technical Chemist.
1909. Sutherland, Daniel M., Ashgrove, Sunbury Common, Middlesex, Works Manager.
1894. Sutherland, Geo., Ladyton Croft, Bonhill, Scotland, Chemist.
1887. Sutherland, Jas., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
1906. Sutherland, John, Vril Lodge, Larne Harbour, Co. Antrim, Ireland, Chemical Engineer.
1916. Sutherst, Dr. W. F., Technical Chemist. Retain Journals.
1886. Sutton, F. Napier, 21, Lydford Road, Cricklewood, N.W., Alkali Works Inspector.
1900. Sutton, W. Lincoln, Redwell Street, Norwich, Public Analyst.
1917. Swallow, Albert V., St. Helens Cable and Rubber Co., Ltd., Warrington, Works Chemist.
1913. Swan, J. Waldron, "Purleighs," The Downs, Luton, Beds., Gas Works Chemist.
1917. Swann, Herbert, 47, Upper Wickham Lane, Welling, Kent, Chemist.
1905. Swenarton, W. Hastings, 2, Rector Street, New York City, U.S.A., Patent Lawyer.
1904. Swindells, Seth, Liverpool Road, Kidsgrove, Stoke-on-Trent, Chemist.
1912. Swinden, Dr. Thos., 12, Nether Edge Road, Sheffield, Metallurgist.
1912. Sykes, Charles D., Ivy House, Langley, near Birmingham, Chemical Works Manager.
1902. Sylow, Paul, New Farm Sugar Refinery, Brisbane, Queensland, Analytical Chemist.
1906. Symes, Langford P., Belfast Freezing Works, Christchurch, New Zealand, Chemist.
1906. Symonds, Abram E., Wick Lane Colour Works, Old Ford Road, Bow, E., Colour Manufacturer.
1910. Szilagyi, L. F., 39, Belsize Avenue, London, N.W., Consulting Engineer.

T

1895. Taber, G. H., 18th floor, Frick Building Annex, Pittsburg, Pa., U.S.A., General Manager (Gulf Refining Co.).
1915. Taberner, E., H.M. Factory, Greta, N.B., Technical Chemist.
1914. Tack, Howarth K., Acid Plant, La Refineria, El Aguila S.A., Minatitlan, Vera Cruz, Mexico, Chemical Engineer.
1910. Tainsh, Peter, 36, Green Lawn, Rock Ferry, Cheshire, Technical Chemist.
1915. Tait, J. W., Blackford, Salteats, Ayrshire, Chemist.
1909. Tait, Walter Scott, Innellan, Behington, Cheshire, Works Manager.
- O.M. Takamatsu, T., 13, Nishikatamachi, Hongo, Tokyo, Japan, Analytical Chemist.
- O.M. Takamine, Dr. Jokichi, Takamine Laboratory, Inc., Clifton, N.J., U.S.A., Engineer.
1915. Tallantyre, S. B., H.M. Factory, Chance and Hunt, Ltd., Site B, Oldbury, near Birmingham, Technical Chemist.
1912. Talley, Herbert, c/o Hercules Powder Co., Wilmington, Del., U.S.A., General Manager.
1910. Tanahashi, Dr. T., 1, Yariyacho, Kyobashiku, Tokyo, Japan, Manufacturing Chemist. [Nippon Chem. Industry Co.]
1898. Tanaka, Keishin, Matsuba Hotel, Kudansaka, Uye, Tokyo, Japan, Chemist.
1915. Tangye, Albert W., Thorn, Hartford, Cheshire, Chemical Works Manager (Brunner, Mond & Co.).

1900. Tankard, Arnold R., 67, Ferens Avenue, Cottingham Road, Hull, Analytical Chemist.
1911. Tarver, Percy, 2095, East 36th Street, Cleveland, Ohio, U.S.A., Chemist.
- O.M. Tate, F. H., Winterghyll, Caldys Road, West Kirkby, Analytical and Technical Chemist.
- O.M. Tatlock, R. R., 156, Bath Street, Glasgow, Consulting Chemist.
1902. Tatters, Hugh Lee, 21, Park Road, Hebburn-on-Tyne, Analytical Chemist.
1906. Tattersfield, Frederick, Stortholme, Framlingham, Suffolk, Analyst.
1905. Taveau, René de Mortemer, Experimental Station, E. I. du Pont de Nemours Power Co., Wilmington, Del., U.S.A. (Journals to P.O. Box 244, Wilmington, Del., U.S.A.), Chemist.
1903. Taylor, Alvin M., c/o General Chemical Co., Hege-
wisch, Ill., U.S.A., Chemist.
1917. Taylor, Arthur, "The Woodlands," Langley,
Macclesfield, Technical Chemist.
1902. Taylor, Arthur, P., 12, Willington Street East,
Toronto, Canada, Soap Manufacturer.
1886. Taylor, G. Crosland, Crane House, Crane Wharf,
Chester, Electrical Engineer.
1894. Taylor, G. Midgley, Caxton House, Westminster,
S.W., Analytical Chemist.
- O.M. Taylor, H. E., 1, Alexandra Park Gardens, Glasgow,
Lead Works Manager.
1917. Taylor, Henry F., Holly House, 299, Eccles New
Road, Salford, Works Chemist.
1883. Taylor, Jas., "Cartref," Brierley Street, Mosman,
N.S.W., Australia, Government Metallurgist.
1898. Taylor, Jas. M., Tynevale, Groes Road, Cressington,
Liverpool, Analytical Chemist.
1888. Taylor, J. Scott, North London Colour Works,
Spring Place, Kentish Town, N.W., Technical
Chemist.
1896. Taylor, Martin, Abbotsmead, St. Albans, Herts,
Chemical Works Manager.
1901. Taylor, Sidney H., 63, Wolstenholme Road,
Sharrow, Sheffield, Works Chemist.
1898. Taylor, Walter, 475, Grosvenor Place, Limefield,
Bury, Lancs, Technical Chemist.
1915. Taylor, W. Ivan, c/o Kynoch, Ltd., Umbogintwini,
Natal, Chemical Works Manager.
1905. Taylor, Wm. H., 36, Glenhouse Road, Eltham Park,
Kent, Chemist.
1916. Tcherniac, Dr. Jos., 49, Palace Road, Streatham
Hill, S.W., Consulting Chemist.
1887. Teanby, G. W. A., Elvin Lodge, East Dereham,
Norfolk, Analytical Chemist.
1899. Teas, Wm. Holmes, Marion, Va., U.S.A., Chemist.
- O.M. Teed, Dr. F. L., Chem. Lab., 9, Mincing Lane,
London, E.C., Analytical Chemist.
1905. Teeple, Dr. J. E., 50, East 41st Street, New York
City, U.S.A., Director.
1915. Tefit, H. Delano, 75, Chelsea Avenue, Toronto,
Canada, Chemist.
1904. Teller, George L., 31, North State Street, Chicago,
Ill., U.S.A., Chemist.
1906. Tempny, Dr. Harold A., Department of Agriculture,
Reduit, Mauritius, Analyst.
1916. Templeman, W. H., 53, Fountain Street, Hull,
Chemist and Barrister-at-Law.
1884. Tennant, Jas., Fairlie, Ayrshire, Lead and Colour
Manufacturer.
1896. Tennille, Geo. F., c/o Southern Cotton Oil Co.,
206, Bay Street East, Savannah, Ga., U.S.A.,
Chemist.
1908. Terleski, Fred. H., Oakwood, Hilton Lane, Prestwich,
Manchester, Technical Chemist.
1911. Terrey, Augustus G., 6, Alexandra Road, South
Woodford, Essex, Chemist.
1884. Terry, Hubert L., (Journals) Fairfield House,
Brook Road, Fallowfield, Manchester; and
(Laboratory) 23, Hopwood Avenue, Manchester
Consulting Chemist.
- O.M. Tervet, R., 68, Windsor Road, Leyton, Essex,
Oil Works Manager.
1893. Tetley, C. F., Messrs. Jos. Tetley and Sons, The
Brewery, Leeds, Brewer.
1915. Thäberg, N. T., A.B. Lina Myr, Stureplan 13,
Stockholm, Sweden, Technical Chemist.
1903. Thatcher, Ed. J., The Manor House, Chew Magna,
near Bristol, Merchant and Manufacturer.
1909. Thaxter, Gerald N., c/o Brewer and Co., Worcester,
Mass., U.S.A., Chemist.
1908. Thom, Wm. H., 131, Oakwood Avenue, Toronto,
Canada, Chemist.
1911. Thomas, D. Hibbert, 56, Waun Road, Morriston,
Glamorganshire, Chemical Works Manager.
1916. Thomas, E. R., The Farm, H.M. Factory, Sandy-
croft, near Chester, Chemist.
1912. Thomas, Frederick, c/o Williams Bros. and Co.,
Colour Manufacturers, Hounslow, Middlesex,
Chemist and Works Manager.
1894. Thomas, H. Russell, Broad Plain Soap Works,
Bristol, Soap Manufacturer.
1909. Thomas, John, Highfield, Brettell Lane, near
Stourbridge, Analytical Chemist.
1916. Thomas, John S. G., Physical Laboratory, South
Metropolitan Gas Co., 709, Old Kent Road,
London, S.E., Physicist.
1902. Thomas, Nehemiah M., Wellesley Road, Pymble,
N.S.W., Australia, Inspector.
1901. Thomas, Octavins, Gas and Water Office, Pentre,
Glamorganhire, Gas and Water Engineer.
1908. Thomas, Oswald J. D., c/o The E. B. Eddy Co.,
Hull, Quebec, Canada, Research Chemist.
1888. Thomas, S. Percy, c/o Baird and Tatlock, (London)
Ltd., 14, Cross Street, Hatton Garden, London,
E.C., Technical Chemist.
1898. Thomas, Wm. Harrison, jun., South Norwalk,
Conn., U.S.A., Printworks Chemist.
1905. Thomlinson, Wm., Seaton Carew Ironworks, West
Hartlepool, Ironmaster.
1905. Thompson, Alf. J., c/o R. W. Greeff and Co.,
Thames House, Queen Street Place, London,
E.C., Chemical Merchant.
1916. Thompson, Bertie, Nile Villa, Meldrum Road,
Kirkcaldy, Journals to Kelvin Lodge, 59,
Northumberland Park, Tottenham, N., Tech-
nical Chemist.
1885. Thompson, Prof. Claude M., 38, Park Place, Cardiff,
Professor of Chemistry.
1898. Thompson, Edw. C., 9, Elderslie Road, Eltham,
London, S.E., Manufacturing Chemist.
1909. Thompson, Edwin, 25, Sefton Drive, Liverpool,
Manufacturing Chemist.
1914. Thompson, F. C., 183, Hyde Park Road, Leeds,
Demonstrator in Leather Industries Department.
1893. Thompson, G. Rudd, 69, Dock Street, Newport,
Mon., Analytical and Consulting Chemist.
1895. Thompson, Gustave W., 129, York Street, Brooklyn,
N.Y., U.S.A., Chemist.
1913. Thompson, Howard, c/o Wm. Pearson, Ltd., Stone-
ferry, Hull, Analytical Chemist.
1907. Thompson, Jas. G., Donegall Quay Mills, Belfast,
Ireland, Corn Miller.
1903. Thompson, Jno. T., Corporation Sewage Works,
Knostrop, Leeds, Analyst.
1912. Thompson, Kenworthy J., c/o The Columbia Tire
& Rubber Co., Columbiana, Ohio, U.S.A., Rubber
Works Chemist.
1907. Thompson, Milton S., 72, Broad Street, Boston,
Mass., U.S.A., Manufacturer.
1916. Thompson, Wm. F., 140, London Road, Nottingham,
Works Chemist.
- O.M. Thompson, W. P., Patent Office, 6, Lord Street,
Liverpool, Patent Agent.
1896. Thomsen, Alonzo L., Maryland Club, 1, East Eager
Street, Baltimore, Md., U.S.A., Manufacturing
Chemist.
1884. Thomson, G. Carruthers, 53, Bedford Road, Rock
Ferry, Birkenhead, Engineer.
1907. Thomsen, H. N., 918, South Kingsley Drive, Los
Angeles, Cal., U.S.A., Metallurgist.

1891. Thomson, Jas. M., Royal Gunpowder Factory, and (Jnls.) Powder Mill Lane, Waltham Abbey, Essex, Manager (Cordite Branch).
1884. Thomson, Robt. T., 156, Bath Street, Glasgow, Analytical Chemist.
1899. Thomson, Thos., c/o Waterproofing Co., Barrhead, near Glasgow, Manufacturer.
- O.M. Thomson, W., Royal Institution Laboratory, 79A, Princess Street, Manchester, Analytical and Consulting Chemist.
1915. Thomson, W. Loekerbie, 34, Craighouse Avenue, Morningside, Edinburgh, Chemist.
1890. Thomaon, Wm. Thos., "Stanton," Parkestone Road, Poole, Dorset, Explosives Chemist.
1902. Thorburn, Jas., 30, Cromartie Avenue, Newlands, Glasgow, Analytical Chemist.
1910. Thorne, Carl B., c/o Riordan Paper Co., Hawkebury, Ontario, Canada, Manager.
- O.M. Thorne, Dr. L. T., Highlands, The Crescent, Belmont, Surrey, and (Journals) Southampton Wharf, Battersea, S.W., Technical Chemist.
1916. Thorne, P. C. L., 40, Kidbrook Park Road, Blackheath, S.E., Works Chemist.
1907. Thornwell, A. R., 163, Rood End Road, Oldbury, Birmingham, Works Chemist.
- O.M. Thorneycroft, Wallace, (Jnls.) Plean House, Plean, Stirling, and 113, St. Vincent Street, Glasgow, Technical Chemist.
1904. Thornley, Thomas, 19, Hope Street, Glasgow, Chemical Manufacturer.
1895. Thorp, Dr. Frank H., 220, Mount Vernon Street, West Roxbury, Mass., U.S.A., Assistant Professor of Industrial Chemistry.
1906. Thorp, Walter, Sorrentoville, Dalkey, Co. Dublin, Ireland, Analytical Chemist.
- O.M. Thorpe, Sir Edward, C.B., F.R.S., Whinfield, Salcombe, South Devon, Professor of Chemistry.
1905. Thorpe, Prof. J. F., C.B.E., F.R.S., The Imperial College, South Kensington, London, S.W., Professor of Organic Chemistry.
1915. Threlfall, Sir R., K.B.E., F.R.S., Oakhurst, Church Road, Edgbaston, Birmingham, Chemical Manufacturer.
1905. Thresh, Dr. John C., Chelmsford, Essex, Medical Officer of Health and Sanitary Expert.
1898. Thurnauer, Dr. Gustav, c/o Aurora Metal Co., Aurora, Ill., U.S.A., Chemist.
1904. Thurston, Azor, Grand Rapids, Ohio, U.S.A., Chemist.
1916. Thwaite, Alwyn H., Northwood, Bowden Close, Crook, Co. Durham, By-Product Coke Oven Manager.
1904. Tickle, Thos., Laboratory, 83, Queen Street, Exeter, Analyst.
1913. Tilburn, Charles, The Australian Explosives and Chemical Co., Ltd., Brabrook, Vic., Australia, Works Manager and Explosives Chemist.
1917. Tilden, Philip S., 317, South 43rd Street, Philadelphia, Pa., U.S.A., Sales Manager.
1900. Tilley, Jas. W., 95A, Southwark Street, London, S.E., Research Chemist.
1906. Tillson, Henry E., 5858, Pine Street, Philadelphia, Pa., U.S.A., Dyer.
1901. Timmans, W. G., The Basford Chemical Co., Ltd., Basford, Nottingham, Chemical Manufacturer.
1917. Ting, Su H., c/o Mr. H. C. Chen, 11, Tar-Wang-Mu Lane, Wush, Kiangsu, China (via Siberia), Chemist.
1916. Tinniswood, Joseph, c/o Hough, Hoscason and Co., 2, Bridge Street, Manchester, Wholesale Druggists Manager.
1894. Tipler, Fred. C., 2, Wellington Villas, Crewe, Analytical Chemist.
1907. Tischbein, Dr. Robert, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1894. Toch, Maximilian, 320, Fifth Avenue, New York City, U.S.A., Chemist.
1915. Tocher, Dr. J. F., Crown Mansions, Union Street, Aberdeen, Public Analyst.
1886. Todd, A. M., c/o The A. M. Todd Co., Kalamazoo, Mich., U.S.A., Manufacturing Chemist and Distiller of Essential Oils.
1911. Todd, Fred W., 16, Lansdowne Road, Tonbridge, Kent, Chemist.
1913. Tomlinson, George G., Anglo-Chilian Nitrate and Railway Co., Tocopilla, Chile, South America, Chemist.
1914. Tompkin, Albert, 101, Lenton Boulevard, Nottingham, Pharmacist.
- O.M. Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
1902. Tone, Frank Jerome, c/o The Carborundum Co., Niagara Falls, N.Y., U.S.A., Manager.
1909. Tonry, Wm. S., Passaic Street, near Elm Street, Maywood, N.J., U.S.A., Chemical Engineer.
1913. Toppin, Richmond D., No. 9212, 1st Australian Dermatological Hospital, A.I.F., Bulford, Wiltshire, Chemist.
1916. Torpy, Hubert L., Carlton Brewery, Melbourne, Australia, Brewer.
1907. Torrey, Dr. Joseph, Park Drive, Blundellsands, Liverpool, Engineer.
- O.M. Towers, J. W., Widnes, Lancashire, Analytical Chemist.
1907. Towler, A. E., c/o Sulphide Corporation, Cockle Creek, N.S.W., Australia, Chemist.
1915. Townsend, Clinton P., 918, F. St. N.W., Washington, D.C., U.S.A., Patent Lawyer.
1897. Towse, Walter, c/o Clark, Son & Morland, Ltd., Glastonbury, Technical Chemist.
1904. Toyne, Francis D., c/o Kelaal and Kemp, Ltd., Woodhouse Mills, Norden, near Rochdale, Chemist.
1899. Trantom, Dr. Wm., Borås, Grappenhall, near Warrington, Chemist.
1894. Traphagen, Dr. Frank W., Colorado School of Mines, Golden, Colo., U.S.A., Professor of Metallurgy and Assaying.
1900. Traquair, Jno., Ayer, Mass., U.S.A., Analytical Chemist.
1906. Travell, Norman E., Grosvenor Avenue, Mapperley Park, Nottingham, Lace Dresser. On Active Service, retain Journals.
1893. Travers, Dr. Morris W., F.R.S., Beacon Hall, Priory Gardens, Highgate, London, N.; Journals c/o Duroglass Ltd., Blackhorse Lane, Walthamstow, Essex, Professor of Chemistry.
1889. Trechmann, A. O., Dene Garth, Springfield Avenue, Harrogate. Journals to Trechmann Bros., West Hartlepool. Cement Manufacturer.
1911. Trechmann, C. T., Warren Cement Works, Hartlepool, Cement Manufacturer.
1895. Treharne, F. Gwilym, Wrangbrook, Llanishen, near Cardiff, Analytical Chemist.
1901. Trigger, Oliver, Chem. Dept., Royal Arsenal, Woolwich, S.E., Analytical Chemist.
1898. Tripp, Dr. E. Howard, 9, Westbury Road, Woodside Park, London, N., Editor.
- O.M. Trobridge, A., c/o Trobridge and Co., Ltd., Heworth Shore, Felling-on-Tyne, Technical Chemist.
1916. Tromp, Felix J., Transvaal University College, Pretoria, S. Africa, Research Chemist.
1897. Trotman, Saml. R., The City Laboratory, 1, Regent Street, Nottingham, City Analyst.
1887. Tsukiyama, S., c/o Nippon Senrio Seizo, Kaisha Works, Kawakishi-Cho, Nishiku, Osaka, Japan, Paper Mills Chemist.
1916. Tuck, Dr. Wm. B., 45, Bartholomew Road, London, N.W., Chemist.
1894. Tucker, Alex. E., 55, Station Street, Birmingham, Metallurgist and Chemist.
1897. Tucker, Samuel A., Columbia University, New York City, U.S.A., Tutor in Industrial Chemistry.
1886. Tuer, Arthur H., Douglas House, Worthington, near Wigan, Analytical Chemist.
1903. Tufts, C. G., c/o Semet-Solvay Co., Syracuse, N.Y., U.S.A., Chemical Engineer.

1909. Tulloch, Capt. T. G., Bank Buildings, St. James's Street, London, S.W., Director of Public Companies.
1901. Tulloch, Wm. F., c/o The Olympia Oil & Cake Co., Ltd., Olympia Mills, Selby, Merchant.
1914. Tungay, Sydney J., Haughton's Ltd., 30, St. Mary at Hill, London, E.C., Chemical Engineer.
1909. Tunks, Dr. F. R., Powder Mills, Tonbridge, Kent, Manager.
1904. Tunnell, Raymond W., 251, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Manufacturer.
1899. Turnbull, Dr. Andrew, 18, Hackins Hey, Liverpool, Consulting Chemist.
1888. Turnbull, G. W., Ash Cottage, North Road, Carnforth, Lancashire, Metallurgical Chemist.
1916. Turnbull, John, c/o 44A, Moore End, Spondon, by Derby, Analytical Chemist.
1904. Turnbull, R. H., Messrs. Turnbull's (Glasgow) Ltd., 10, Strand Road, Calcutta, India, Chemist.
1884. Turnbull, W. S., 38, Bath Street, Glasgow, Chemical Manufacturer.
1911. Turner, Prof. A. J., Technical Institute, Byculla, Bombay, India, Professor of Chemistry.
1917. Turner, Francis M., jun., Room 272, 1, Madison Avenue, New York, Chemical Engineer.
1915. Turner, James, c/o Read, Holliday and Sons, Ltd., 8-10, West Market Street, Toronto, Canada, Manufacturing Chemist.
1902. Turner, Jos., c/o British Dyes, Ltd., and (Jnls.) Azo House, Birkby, Huddersfield, Director.
1905. Turner, Prof. Thomas, 75, Middleton Hall Road, King's Norton, Birmingham, Professor of Metallurgy.
1917. Turner, Dr. W. E. S., The University, Sheffield, Hon. Secretary, Society of Glass Technology.
1887. Turney, Sir J., Trent Bridge Leather Works, Nottingham, Tanner.
1908. Turnill, Thos. W., c/o Atlas Preservative Co., Ltd., Windmill Lane, Deptford, S.E., Works Chemist.
1916. Tuttle, Dr. F. E., 125, East Maxwell Street, Lexington, Ky., U.S.A., Professor of Chemistry.
1905. Tutwiler, Carrington C., Real Estate Trust Building, Philadelphia, Pa., U.S.A., Consulting Gas Chemist.
1916. Tweedie, Geo. R., 2, Hambledon Road, Southfields, S.W., Technical Chemist.
1890. Tweedy, Jas., 245, Burdett Road, Limehouse, E., Metallurgical Chemist.
1905. Twigg, Geo. F., Gas Works, Castleford, Yorks, Gas Works Chemist.
1915. Twiss, Dr. D. F., "Glendevon," Royal Road, Sutton Coldfield, Chief Chemist, Dunlop Rubber Co.
1891. Twitchell, E., Wyoming, Ohio, U.S.A., Candle Works Manager.
1913. Twomey, Jerome, 21, Onslow Road, Elm Park, Liverpool, Research Chemist.
- O.M. Twynam, T., Wynyard House, Coatham Road, Redcar, Yorks, Metallurgist.
1904. Tyler, Chas. R., c/o Dr. Francis Wyatt, 402, West 23rd Street, New York City, U.S.A., Analytical Chemist.
- O.M. Tykke, P. G. W., Lawn House, New Malden, Surrey, Chemical Manufacturer.
- O.M. Tyrer, Thos., Stirling Chemical Works, Stratford, E.; and (Journals) 14, Sandwell Mansions, West End Lane, N.W., Chemical Manufacturer.
1905. Umney, John C., 48, Southwark Street, London, S.E., Wholesale Druggist.
1889. Underhill, Thos. J., 53, Lanecost Road, Tulso Hill, S.W., Inspector of Stoves.
1885. Underwood, G. R., 10, Emerson Street, Peabody, Mass., U.S.A., Glue Works Chemist.
1917. Upton, Adolph W. H., Brooklyn, Tavistock Road, South Woodford, London, E., Research Chemist.
1915. Upton, W. C., Tara Cook Street, Randwick, Sydney, N.S.W., Soap and Candle Manufacturer.
1916. Urwin, Alfred, Urwin and Co., The Manors, Newcastle-on-Tyne, Manufacturing Chemist.

V

1911. Vakil, Kapibram H., "Ivyhurst," Burlington Road, Altrincham, Chemist.
1915. Valentine, Geo., Engineer's Dept., St. James' Gate Brewery, Dublin, Chemical Engineer.
1916. Vance, John F. C. B., 947, Richard Street, Vancouver B.C., Canada, City Analyst.
1896. Van der Linde, Dr. Harold, 142 Western Road, Toronto, Ontario, Canada, Rubber Chemist.
1895. Vanderpool, Dr. Frank, 175, Park Avenue, Orange, N.J., U.S.A., Chemist.
1903. Van Dyck, Edwin M., 57, Greene Street, New York City, U.S.A., Chemist and Ink Maker.
1897. Van Gelder, Arthur P., c/o Hereules Powder Co., Wilmington, Del., U.S.A., Superintendent.
1891. Van Gundy, Chas. P., Laboratory, B. and O. R. R., Baltimore, Md., U.S.A., Metallurgical Chemist.
1896. Van Laer, Norbert, 6, Emerson Road, Ilford, Essex, Brewer and Chemist.
1897. Van Marken, J. C., 32, Zeekant, Scheveningen, Holland, Chemical Engineer.
1888. Vargas-Vergara, J. M., Apartado No. 120, Bogota, Colombia, S. America, Metallurgical Chemist.
1910. Vass, David, Gas Works, Perth, Manager.
1915. Vaughan, F. W., H. R. Vaughan and Co., Ltd., South Shore Road, Gateshead-on-Tyne, Roofing Felt Manufacturer.
1912. Ventress, Ernest W. S., 48, Queen's Road, Richmond, Surrey, Oil Mill Manager.
1898. Verity, Ben., 550, Hood Street, Fall River, Mass., U.S.A., Print Works Chemist.
1908. Vickers, Benj. Threlfall, Gascoigne Street, Boar Lane, Leeds, Oil Merchant.
- O.M. Vickers, Wm., c/o Thos. Vickers and Son, Miles Platting, Manchester, Chemical Manufacturer.
1916. Vincent, F. D'Abernon, Branksome Court, Fleet, Hants., Explosives Manufacturer.
1909. Virolleaud, Leopold, 3, Rue de Paris, St. Denis, Seine, France, Chemical Engineer. On active service.
1897. Vlies, Leonard E., Belmont, Gowan Road, Alexandra Park, Manchester, Aniline Dye Manufacturer.
- O.M. Voelker, E. W., 1, Tudor Street, London, E.C., Analytical and Consulting Chemist.
1887. Voelker, Dr. J. A., 20, Upper Phillimore Gardens, Kensington, W., Agricultural Chemist.
1897. Vogel, Julius L. F., High Speed Steel Alloys, Ltd., Ditton Road, Widnes, Engineer.
1897. Voorhees, Louis A., 111, Carroll Place, New Brunswick, N.J., U.S.A., Agricultural Chemist.
1899. Voorhees, Samuel S., Bureau of Standards, Washington, D.C., U.S.A., Chemist.
1899. Voss, Walter A., Carlton Chemical Works, Glengall Road, Millwall, E., Manufacturing Chemist.
1916. Vowler, John N., 54, Gondar Gardens, West Hampstead, London, N.W., Research Chemist.
1916. Vries, Dr. Otto de, Buitenzorg, Java, Director of the Central Rubber Station.

W

1905. Waddell, Montgomery, 30, Church Street, New York City, U.S.A., Consulting Engineer.
1916. Waddell, R. Henderson, The Standard Chemical Co., 9, White Cross Place, Wilson Street, E.C., Chemical Manufacturer.

U

1911. Waddock, Wm. P., 666, Harris Street, Ultimo, Sydney, N.S.W., Milk Analyst.
1913. Wade, Albert J., c/o Fowler Ltd., Sugar Refiners, Blackwall, E., Sugar Analyst.
1916. Wade, Arthur E. L., 28, West Kensington Gardens, W., Manufacturing Chemist.
1917. Wade, Ernest G., Dinting Vale Print Works, Dinting, near Manchester, Analytical Chemist.
1902. Wade, Frank, 26, St. Ronan's Avenue, Southsea, Hants. Analytical Chemist.
1890. Wade, Jas. L., 28, West Kensington Gardens, London, W., Chemical Manufacturer. Retain Journals.
1915. Wade-Wilton, E., Planet Works, Bramley, near Leeds, Chemical Manufacturer.
1889. Wadman, W. E., 102, Lord Avenue, Bayonne, N.J., U.S.A., Manufacturing Chemist.
1911. Waele, Armand de, Aeronautical Inspection Department, University College, Gower Street, W.C.; (Journals to "Dundee," Rosefield Road, Staines), Technical Chemist.
1897. Wagner, Dr. Theodore B., Room 2229, 17, Battery Place, New York City, U.S.A., Chemist.
1893. Wagner, W. G., 12, North Common Road, Ealing, W., Manufacturing Chemist.
1906. Wagstaffe, Dr. E. A., 22, Blackfriars Street, Manchester, Analytical Chemist.
1906. Wahl, Dr. Robert, 1135-1147, Fullerton Avenue, Chicago, Ill., U.S.A., President, Brewers' School.
1917. Wainwright, Joseph, "Ellerslie," The Wiend, Lower Bebington, Ches., Manager.
1895. Wainwright, Wm., Dublin Vitriol Works, Ballybough, Dublin, Chemist.
1908. Wait, Douglas, c/o R. Gay and Co., Ltd., Langthorne Works, Stratford Market, London, E., Analytical Chemist.
1916. Waites, Harold, 44, Cranbrook Avenue, Cottingham Road, Hull, Analytical and Research Chemist.
1899. Wakefield, Wm. C., Mill Street East, Savile Town, Dewsbury, Chemical Manufacturer.
1915. Waldo, Dr. Leonard, 49, Wall Street, New York City, U.S.A., Consulting Engineer.
1895. Waldstein, Dr. Martin E., 23, Broadwater Down, Tunbridge Wells, Kent, Manufacturing Chemist.
1917. Walker, Alexr. B., "Donwal," Kings Road, Welsend-on-Tyne, Gas Engineer.
1887. Walker, Archibald, Nowark Castle, Ayr, Scotland, Distiller.
1915. Walker, Arthur, "Woodbourne," Aneaster Road, Far Headingley, Leeds, Chemical Manufacturer.
1917. Walker, Ernest, c/o Mardon, Son & Hall, The Caxton Works, Bristol, Engineer.
1913. Walker, Frederick Handel, 3, Stannington Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.
1917. Walker, Frederick W., 89, High Street, Welling, Kent, Analytical Chemist.
1908. Walker, George, c/o Burmah Oil Co., Ltd., P.O. Box 67, Rangoon, Burmah, Analytical Chemist.
1913. Walker, Henry, "Thornfield," 65, Madeley Road, Ealing, London, W., Chemical Engineer.
1897. Walker, H. V., 323, Ridgo Street, Newark, N.J., U.S.A., Chemist.
1894. Walker, Prof. Jas., F.R.S., 5, Wester Coates Road, Edinburgh, Professor of Chemistry (University of Edinburgh).
1916. Walker, Jas., c/o Jas. Robertson & Co., Ltd., 142, William Street, Montreal, Canada, Chemist.
1897. Walker, Jas. W., Gales Road, Irvine, Scotland, Chemical Manufacturer.
1906. Walker, Jas. W., Farley, Oakamoor, Stoke-on-Trent, Assayer.
1902. Walker, Jno. H., Gourepore Works, Naihati, E.B.S.R., Bengal, India, Chemist.
1910. Walker, John S., Hiratsuka, Sagami, Japan, Explosives Chemist.
1884. Walker, S. R., Fern Bank, Starling Road, Radcliffe, Manchester, Foreman Dyer.
1912. Walker, Prof. W. O., Dept. of Chemistry, School of Mining, Kingston, Ont., Canada, Professor of Chemistry.
1895. Walker, W. Sloane, c/o Walker, Ltd., Litherland, near Liverpool, Tanner.
1916. Wall, Prof. E. J., Syracuse University, Syracuse, N.Y., U.S.A., Professor of Photography.
1916. Wall, Ernest D., Châlet, Grove Hill, Woodford, N.E., Technical Chemist.
1897. Wallace, Edwin C., 92, Corey Street, West Roxbury, Mass., U.S.A., Chemist.
1897. Wallace, Robt. A., 66, Holland Road, London, W., Chemical Manufacturer.
1917. Wallace, Thos., c/o Castner Kellner Alkali Co., Wallsend, Northumberland, Works Chemist.
- O.M. Waller, Dr. Elwyn, 7, Franklin Place, Morristown, N.J., U.S.A., Professor of Chemistry.
1906. Wallerstein, Leo, 171, Madison Avenue, New York City, U.S.A., Chemist.
1899. Wallerstein, Dr. Max, 171, Madison Avenue, New York City, U.S.A., Chemist.
1916. Walley, Robert J., Canadian Explosives, Ltd., Shand Works, James Island, B.C., Canada, Chemical Engineer and Superintendent.
1917. Walls, Ernest, The Garthe, Pereival Road, Clifton, Bristol, Soap Manufacturer.
1916. Walmsley, Wm. A., c/o Hardman & Holden, Ltd., Colliery Street, Clayton, Manchester, Works Manager.
1886. Walsh, F. T., 12, Valentine Street, West Newton, Mass., U.S.A., Colour Printer.
1901. Walsh, Lionel O. P., c/o Dominion Tar and Chemical Co., Ltd., Sydney, Cape Breton, Canada, Chemist.
1903. Walsh, Peter H., P.O. Box 569, Magog, Quebec, Canada, Analytical Chemist.
1915. Walter, Albert, c/o Stauffer Chemical Co., Chauncey, New York, U.S.A., Works Manager.
1904. Walther, Wm., Holzapfel's Compositions Co., Ltd., Heworth Shore, Felling-on-Tyne, Chemist and Works Manager.
1908. Walton, Robert H., Railway Stores, Newtown, Sydney, N.S.W., Analyst.
1911. Walton, Wm. Keighley, Beechwood, Upper Rushton Road, Thornbury, Bradford, Analyst.
1895. Want, W. Philip, 194-200, Bishopsgate, London, E.C., Pharmacist and Editor.
1901. Warburton, Frank, 50, Rosebery Road, Muswell Hill, N., Manager.
1916. Warburton, F. W., "The Hämsted," Norman Road, Runcorn, Cheshire, Technical Chemist.
1904. Warburton, George H., 75, Mill Lane, West Hampstead, N.W., Analytical Chemist.
1915. Warburton, Stanley, Titaghur Paper Mills, Ltd., Titaghur, Calcutta, India, Analytical Chemist.
1896. Warburton, Thos., Rathlin, Birch Hall Lane, Rusholme, Manchester, Chemist.
- O.M. Ward, Geo., Messrs. Hirst, Brooke, and Hirst, Ltd., Millgarth Mills, Leeds, Chemical Manufacturer.
1891. Ward, G. J., Hallam Fields, Ilkeston, Notts, Civil Engineer.
1898. Ward, John, Barnstone Blue Lias Lime Co., Ltd., Barnstone, Notts, Manager.
1899. Ward, Wm. J., 28, Sefton Road, Sale, Manchester, Chemist.
1917. Wardlaw, Thomas D., 23, Scott Street, Toronto, Canada, Agent for Dyes & Chemicals.
1917. Wardlaw, William, The University, Edmund Street, Birmingham, Lecturer in Chemistry.
1908. Wardleworth, Theo. H., 32, St. Gabriel Street, Montreal, Canada (Journals to c/o Explosives Dept., Imperial Munitions Board, Ottawa, Canada), Wholesale Druggist.
1902. Waring, W. Geo., Webb City, Mo., U.S.A., Metallurgical Chemist.
1913. Warner, Arthur L. D., P.O. Box 203, Edgewater, N.J., U.S.A., Sugar Refiner.
1899. Warnes, Arthur R., 47, Cranbrook Avenue, Cottingham Road, Hull, Consulting Technical Chemist.
1912. Warren, E. Bruce, c/o India Rubber Gutta Percha Telegraph Works, Ltd., Silvertown, E., Consulting Analytical Chemist.
1890. Warren, Fiske, c/o S. D. Warren and Co., Laboratory, Cumberland Mills, Maine, U.S.A., Paper Manufacturer.

1901. Warren, Jno. E., Eagle Chemical Works, Barchester Street, Poplar, E., Tar Distiller.
1913. Wassmer, Dr. E., 2, Boulevard de la Tour, Geneva, Switzerland, Chemist.
1917. Waterfall, Chas. J., 4, Queen Square, Bristol, Analytical Chemist.
1917. Waterfall, Robinson, 4, Redland Court Road, Bristol, Acid and Fertilizer Manufacturer.
1917. Waterhouse, Carl N., c/o Thermit Ltd., 675, Commercial Road, Poplar, E., Metallurgical Chemist.
1917. Watkins, Edwin F., 561, Bourke Street, Melbourne, Victoria, Australia, Technical Chemist.
1902. Watkins, E. J., 72, King's Road, Peckham, S.E., Works Chemist.
1898. Watkins, Willard H., c/o Schoellkopf, Hartford and Hanna Co., P.O. Drawer 57, Buffalo, N.Y., U.S.A., Chemist.
1894. Watmough, Benj., c/o Brotherton and Co., Ltd., Ammonia Works, Calder Vale, Wakefield, Analytical Chemist.
1884. Watson, Chas., Rose Bank, School Road, Moseley, Birmingham, Manufacturing Chemist.
1894. Watson, Chas. Ernest, 33, Oxford Road, St. Anne's-on-Sea, Lancashire, Chemical Assistant.
1908. Watson, C. I. Wilkinson, c/o Wailuku Sugar Co., Wailuku, Mani, Hawaiian Islands, Chemist.
1901. Watson, Herbert J., 64, Peel House Lane, Widnes, Chemist.
1917. Watson, Herbert W., "Stoneleigh," The Drive, Roundhay, Leeds, Chemical Manufacturer.
1894. Watson, Jas., Tyne View, Hebburn-on-Tyne, Alkali Works Manager.
1891. Watson, Jno., Langdon, Beaconsfield Road, Blackheath, S.E., Analytical Chemist.
- O.M. Watson, Jno. C., Arnold Printworks, North Adams, Mass., U.S.A., Printworks Chemist.
- O.M. Watt, A., c/o Macfie and Sons, 34, Moorfields, Liverpool, Sugar Works Chemist.
1901. Watt, Francis L., City Mart Building, 5, Hamilton Street, Sydney, N.S.W., Australia, Analytical Chemist.
1906. Watt, Dr. H. E., 2, Abinger Gardens, Edinburgh, W., Chemist.
1917. Watterson, James H., Braeside, Mag-dale, Honley, Huddersfield, Chemist.
1916. Watts, Hugh E., Gordon House, Hutton, Essex, Technical Chemist.
1916. Wattleworth, D. R., 6, Dean Street, Workington, Cumberland, Technical Chemist.
1893. Watts, Jno. Isaac, Fairleigh, Hartford, Cheshire, Alkali Works Manager.
1908. Watts, Jno. Wm., Newcastle Tar Works, Blaydon-on-Tyne, Manager.
1907. Waunsley, Harry, 14, Jesmond Avenue, Wembley Hill, London, N.W., Chemical Engineer.
1903. Wayland, Wm. A., 12, Albert Road, Brockley, S.E., Manufacturing Chemist.
1906. Webb, Frank H., 46, Swan Street, Lawrence, Mass., U.S.A., Chemist.
1915. Webber, Arthur H., 16, Thorndike Street, Beverly, Mass., U.S.A., Chemist.
1901. Webster, Geo. J., P.O. Box 1003, Marquette, Mich., U.S.A., Secretary.
1897. Wedge, Utley, Ardmore, Pa., U.S.A., Chemist.
1902. Weed, Hy. T., 471, Stratford Road, Brooklyn, N.Y., U.S.A., Teacher of Chemistry.
1893. Weeks, H. B., 2, Infield Park Road, Barrow-in-Furness, Analytical Chemist.
1904. Weil Jacob A., "Helvetia," Leicester Road, Higher Broughton, Manchester, Chemical Engineer.
1906. Weir, James, c/o Imperial Varnish and Color Co., 6-24, Morse Street, Toronto, Canada, Chemist.
1902. Weiskopf, Dr. Eric H., See Whytehead, Dr. Eric H.
1910. Weiss, John M., c/o Barrett Co., 17, Battery Place, New York City, U.S.A., Chemist.
1908. Weissmüller, Edward F., Spring Lodge, Helsby, Cheshire, Chemist.
1905. Weissmüller, Ernest C., Rockcliffe, Helsby, Cheshire, Research Chemist.
1910. Welch, Bertie M., 80, Hunter Street, Sydney, N.S.W., Australia, Assayer.
1912. Weld, Fred. C., 263, Fairmount Street, Lowell, Mass., U.S.A., Analytical Chemist.
1899. Weldon, Leonard E., Hadleigh, Alma Street, Sherwood Rise, Nottingham, Dyer.
1903. Wellecome, Henry S., Snow Hill Buildings, London, E.C., Manufacturing Chemist.
1914. Wells, E. E., 9, Dalhousie Street, Montreal, Quebec, Canada, Chemical Engineer.
1912. Wells, Jas. H., "Tralce," Sketty Road, Swansea, S. Wales, Metallurgist.
1885. Welsh, Jas., Standard Mills, Ferguson Road, Bombay, India, Printworks Manager.
1890. Welsh, Thos. L., 3, Prince's Gardens, Downhill, Glasgow, Analytical Chemist.
- O.M. Welsh, W., Holt Town Oil Works, Manchester.
1905. Welt, Dr. Ida, 25, Quai de Mont Blanc, Geneva, Switzerland, Chemist.
1906. Wenger, Major Francis E., The Brampton, Newcastle, Staffs., Ceramic Colour Manufacturer.
1909. Wescott, J. P., jr., 224, Calvary Street, Waltham, Mass., U.S.A., Manager.
1903. Wesener, Dr. John A., 31, North State Street, Chicago, Ill., U.S.A., Consulting Chemist.
1889. Wesson, D., 111, South Mountain Avenue, Montclair, N.J., U.S.A., Cotton-oil Expert.
1908. West, Chas. A., c/o American Camphor Refining Co., 14, Fulton Street, Boston, Mass., U.S.A., President.
1909. West, Percy C. H., 61-62, Chancery Lane, London, W.C., Analytical Chemist.
1917. Westmoreland, Wm. R., c/o Thomas Adams, Ltd., Sherwood Hill Works, Nottingham, Works Manager.
1898. Weston, David B., Sharon, Mass., U.S.A., Chemist.
1894. Weston, Robt. S., 14, Beacon Street, Boston, Mass., U.S.A., Chemist and Bacteriologist.
1890. Wetter, Jasper, Room 23, Holborn Hall, Gray's Inn Road, London, W.C., Patent Agent.
1912. Weyman, Geoffrey, The Cwm, Saltwell Road, Low Fell, Co. Durham, Technical Chemist.
- O.M. Whalley, L. J. de, 18, Blandram Road, Lee, S.E., Sugar Chemist.
1916. Wharton, Edward, Rosemont, Station Road, Brimington, Chesterfield, Chemist.
1909. Wharton, Fredk. M., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Chemist.
1917. Wheatley, William, 16, Rathbone Road, Warley Woods, Smethwick, Birmingham, Works Chemist.
1908. Wheaton, H. J., 5, Walton New Road, Lower Walton, Cheshire, Chemical Engineer.
1909. Wheeler, Edward, Ailsa View, 10, Melbourne Terrace, Salteeots, Ayrshire, Demonstrator of Chemistry.
1898. Wheeler, Dr. Edwd. J., 79, Chapel Street, Albany, N.Y., U.S.A., Analytical Chemist.
1903. Wheeler, Ernest, c/o Chemical Lab., Crossley Bros. Ltd., "Otto" Gas Engine Works, Openshaw, Manchester, Metallurgical Chemist.
1906. Wheeler, Frank G., 683, Harris Street, Appleton, Wis., U.S.A., Chemist (Bleach Process Co.)
1907. Wheeler, Dr. R. Vernon, Home Office Experimental Station, Eskmeals, Cumberland, Chemist.
1912. Wheeler, Thorne L., c/o Edible Products Co., 156-186, East 22nd Street, Bayonne, N.J., U.S.A., Chemist.
1916. Wheldon, A. H. F., 200, Amesbury Avenue, Streatham, S.W., Chief Chemist (Natal Estate Co.).
1915. Whetmore, S. A. H., c/o British Dyes, Ltd. Empire House, Kingsway, London, W.C., Secretary.
1909. Whiffen, G. Goodman, Lombard Road, Battersea, London, S.W., Chemical Engineer.
- O.M. Whiffen, Thos. J., Cerris House, West Hill, Putney, S.W., Manufacturing Chemist.
- O.M. Whiffer, W. G., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.

1916. Whinyates, Leonard, "Glen Mona," Rochdale Road, Blackley, Manchester, Aniline Colour Chemist.
1899. Whitaker, Milton C., 27, William Street, New York City, U.S.A., Chemist.
1895. Whitaker, Thos., Aire Vale Dye Works, Newlay, near Leeds, Dyer.
- O.M. Whitaker, Thorpe, (Journals) Bradford Dyers' Association, Ltd., and 35, Pemberton Drive, Bradford, Yorks, Dyer's Chemist.
1915. White, Albert S., "Fairlawn," Bromborough, Cheshire, Chemist.
1893. White, Arthur F., 2, Melbourne Grove, Thornbury, Bradford, Yorks, Manufacturing Druggist.
1915. White, Gerald N., 15, West End Avenue, Pinner, Middlesex, Research Chemist.
1898. White, Jno., County Offices, St. Mary's Gate, Derby, Public Analyst to County of Derby.
1911. White, John W., c/o E.C. Powder Co., Green Street Green, Dartford, Kent, Works Chemist.
- O.M. White, Paul T., Hortonfield House, West Drayton, Chemical Manufacturer.
1910. White, P. Winzar, Viewswley Chemical Works, West Drayton, Middlesex, Manufacturing Chemist, On Active Service.
1911. White, Walter W., c/o Citro Chemical Co., Maywood, N.J., U.S.A., Secretary and Manager.
1912. Whitehead, Charles E., Devonshire Villas, Barrow Hill, near Chesterfield, Derbyshire, Chemist.
1903. Whitehouse, P. L., 16, Lombard Street, West Bromwich, Staffordshire, Oil Chemist.
1906. Whiteley, C. E., 21, Brudenell View, Leeds, Demonstrator of Chemistry.
1885. Whiteley, R. Lloyd, The Institute, West Bromwich, Staffordshire, Principal.
1892. Whiteside, Jno. L., 376, St. Helen's Road, Bolton-le-Moors, Chemical Lecturer.
1912. Whitney, Wm. L., c/o U.S. Graphite Co., Saginaw, Mich., U.S.A., Chemist.
1885. Whittaker, C. J., Roetfield, Clitheroe, Chemical Engineer.
1916. Whittaker C. M., 55, Cleveland Road, Huddersfield, Technical Chemist.
1913. Whittelsey, Dr. Theodore, c/o U.S. Rubber Co., 11th Avenue and 58th Street, New York City, U.S.A., Chemical Director.
1904. Whittier, Charles T., 78, Brinkerhoff Street, Jersey City, N.J., U.S.A., Manager.
1901. Whitton, Jas. T., Nobel Villas, Ardeer, Stevenston, Ayrshire, Explosives Chemist.
1884. Whowell, F., Croich Hey, Tottington, Bury, Lanes, Bleacher.
1910. Whympere, R., 37, Lovelose Gardens, Surbiton, Surrey, Chemist.
1902. Whythead, Dr. Erie H., c/o Brotherton and Co., Ltd., Leeds, Works Manager.
1899. Wiarda, Jno. C., 259-273, Green Street, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1915. Wibberley, Geo., c/o Mrs. Howlett, 501, Old Kent Road, London, S.E., Technical Chemist.
1913. Wickenden, Leonard, c/o West Virginia Paper and Pulp Co., 521, West 23rd Street, New York City, U.S.A., Research Chemist.
1908. Wickes, Clarence S., 28, Franklin Avenue, Merchantville, N.J., U.S.A., Factory Superintendent.
1915. Wickstead, J. B., c/o Messrs. Lankshear, Wickstead & Co., 17, St. Anne's Square, Manchester, Chemical Manufacturer.
1916. Wiegand, Wm. B., c/o Canadian Consolidated Rubber Co., Papineau Square, Montreal, Canada, Chief Chemist.
1904. Wieler, Eric E., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.
1906. Wiffen, Henry J., 17, Albany Road, Manor Park, Essex, Manufacturing Chemist.
1883. Wiggin, W. W., 55, George Street Parade, Birmingham, Nickel Refiner.
1897. Wigglesworth, H., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
1913. Wigner, J. H., The White Cottage, Helsby, Cheshire, Works Chemist.
1906. Wikner, Sigurd A., "Lynton," Kingsbury Road, Gravelly Hill, Birmingham, Tar Works Chemist.
1915. Wilbraham, Dr. Evelyn C. B., 6, Bury Court, St. Mary Axe, E.C., Chemical Manufacturer.
1899. Wild, Roland C., The Grange, New Eltham, Kent, Analytical Chemist.
1893. Wilder, F. L., Morro Velho, Minas Geraes, Brazil, Assayer.
1902. Wilder, Salmon W., jun., 148, State Street, Boston, Mass., U.S.A., Treasurer.
1911. Wildt, Dr. Edwin, 85, Clarendon Park Road, Leicester, Technical Chemist.
1912. Wiley, Samuel W., 7, South Gay Street, Baltimore, Md., U.S.A., Analytical Chemist.
1916. Willford, A. F., "Eversloigh," Ashville Avenue, Norton-on-Tees, Works Chemist.
1906. Wilke, Wm., 86, Norwood Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.
1903. Wilkie, Jno. M., 5, Balmoral Avenue, West Bridgford, Notts, Analytical Chemist.
1885. Wilkin, Sir Walter, K.C.M.G., Appold Street, Finsbury, E.C., Yeast Manufacturer.
1915. Wilkins, C. R., 8, Crookston Road, Eltham, S.E., Works Chemist.
1916. Wilkinson, C. D., c/o The Penketh Tanning Co., Ltd., Penketh, near Warrington, Leather Chemist.
1911. Wilkinson, Frank, West Lodge, Handsworth near Sheffield, Chemical Manufacturer.
1916. Wilkinson, Herbert Tatlock, c/o The Wardle Engineering Co., Ltd., 196, Deansgate, Manchester, Engineer.
1904. Wilkinson, Prof. J. A., South African School of Mines and Technology, P.O. Box 1176, Johannesburg, Transvaal, Professor of Chemistry.
1886. Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks, Chemical Manufacturer.
1916. Wilks, Leslie P., Hillside, Stone Road, Stafford, Works Chemist (Siemens Bros.).
1893. Willeox, Benjamin, 47, Lincoln's Inn Fields, London, W.C., Patent Agent.
1911. Willeox, Stuart J., c/o United Alkali Co., Ltd., 30, James Street, Liverpool, Chemist.
1916. Williams, Aneurin, 57, Frederiek Street, Widnes, Research Chemist.
1903. Williams, Chas. E., Thornhayea, Sleaford, Seed Crusher.
1895. Williams, David T., 42, Finsbury Square, London, E.C., Chemist and Assayer.
1916. Williams, Dean, 221, Orchard Avenue, Ridgway, Pa., U.S.A., Industrial Chemist.
1912. Williams, Egbert R., York Town, Va., U.S.A., Chemist, Retain Journals.
1891. Williams, Henry J., 30, Norfolk Road, Chestnut Hill, Mass., U.S.A., Chemical Engineer.
1908. Williams, Herbert E., 19, Chatham Grove, Withington, Manchester, Chemist.
1914. Williams, J. A., Mackenzie, c/o A. E. Ames and Co., Union Bank Building, Toronto, Canada.
1904. Williams, Jno. T., 100, Broadway, New York City, U.S.A.
1913. Williams, Jos. H., 54, Dangan Road, Wanstead, Essex, Works Chemist.
1904. Williams, Naboth, 28, Rolleston Street, Warrington, Technical Chemist.
1902. Williams, Percy, 94, Telford Avenue, Streatham Hill, S.W., Chemist.
1916. Williams, Peter, c/o John Lysaght, Ltd., Scunthorpe, Lincoln, General Manager.
1885. Williams, Rowland, 79, Queen Square, Lancaster, Analytical Chemist.
1912. Williams, Samuel B., Homestead, Roskear, Camborne, Cornwall, Metallurgist.
1900. Williams, Saml. H., Glastonbury, Conn., U.S.A., Soap Manufacturer.
1903. Williams, S. M., 269, Springdale Avenue, East Orange, N.J., U.S.A., Chemist.
1885. Williams, T. Howell. See Idris, T. H. W.

1884. Williams, Prof. W. Carleton, Broomgrove, Goring-on-Thames, Professor of Chemistry.
1902. Williams, Walter Scott, Baker's Corner, Attleboro', Mass., U.S.A., Textile Engineer.
1916. Williams, Wm. H., 19, Royal Mint Street, E., Chemist and Assayer.
1887. Williams, W. Collingwood, 36, Dansie Street, Liverpool, Analytical Chemist.
- O.M. Williams, W. J., 1503, Foulkrod Street, Frankford, Philadelphia, Pa., U.S.A., Analytical Chemist.
1894. Williamson, J. Alex., The Croft, Chase Court Gardens, Enfield, N., Analytical Chemist.
1911. Williamson, John, jun., Alne Hill, Camp Road, Maryport, Cumberland. Tanner.
1903. Wills, J. Lainson, 3457, Crittenden Street, St. Louis, Mo., U.S.A., Technical and Brewing Chemist.
1888. Wilson, Cecil H., c/o Sheffield Smelting Co., Ltd., Royd's Mills Street, Sheffield, Chemist.
1888. Wilson, Dr. David, Carbeth, Killearn, by Glasgow.
1885. Wilson, Frank, 7, Bedford Square, London, W.C., Brewer.
- O.M. Wilson, G. E., The Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
1899. Wilson, Gordon, c/o Consuelo Ingles, Zacatecas, Mexico, Chemist and Assayer.
1916. Wilson, Jas. H., 40, Western Road, Cowlesley, Huddersfield, Works Chemist.
1836. Wilson, Jno., Tyneside, 381, Hagley Road, Birmingham, Technical Chemist.
1909. Wilson, Jno., Battersea Polytechnic, London, S.W., Head of Chemical Dept.
1905. Wilson, J. E., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemical Salesman.
1915. Wilson, J. H., Caledonia Engine Works, MacDowall Street, Paisley, Scotland, Engineer.
1902. Wilson, Leonard P., Rosemount, Holyhead Road, Coventry, Technical Chemist.
1910. Wilson, Leslie, West Bank, Doxey, near Stafford.
- O.M. Wilson, R. H., Egglecliffe P.O., Co. Durham, Chemical Manufacturer.
1912. Wilson, S. Siddons. See Siddons-Wilson, S.
1917. Wilson, Thos. A., Corporation Chemical Dept., 20, Trongate, Glasgow, Analytical Chemist.
1908. Wilson, William James, Whangarei Club, Whangarei, New Zealand, Consulting Cement Engineer.
1909. Wilson, Wm. J., Haslemere, Lyndhurst Gardens, Church End, Finchley, N., Chemist.
1890. Wilson, W. W., Dalmonach House, Alexandria, Dumbartonshire, Analytical Chemist.
1912. Windsor, P. L., Library, University of Illinois, Urbana, Ill., U.S.A., Librarian.
1913. Windsor-Richards, W., Siluminite Insulator Co., Ltd., The Green, Southall, Chemist.
- O.M. Wingham, A., 57, Victoria Road South, Southsea, Hants, Metallurgical Chemist.
1907. Winsloe, Louis S., 1, Booth Street, Manchester, Manufacturing Chemist.
1892. Winstanley, Capt. W. Hy., Park Lodge, Willington Road, South Stockport, Technical Chemist.
1886. Winstone, E. H., Members' Mansions, 36, Victoria Street, London, S.W., Ink Manufacturer.
1917. Winton, Albert J., Benwell Cottage, Dene Avenue, Rowlands Gill, co. Durham, Metallurgical Chemist.
1892. Wirtz, Dr. Quirin, 32, Great Ormond Street, London, W.C., Consulting Chemist.
1889. Wishart, Jno., Oakbank Oil Co., Ltd., 29, St. Vincent Place, Glasgow, General Manager.
1917. Witherell, A. L., Fred. Rucping Lea Co., Fond du Lac, Wis., U.S.A., Chief Chemist.
1902. Withers, Prof. W. A., State A. and M. College, West Raleigh, N.C., U.S.A., Professor of Chemistry.
1915. Witmer, H. E., 310, Board of Trade Building, Toronto, Canada, Manufacturers' Agent.
1916. Witte, Wm., c/o U.S. Finishing Co., Norwich, Conn., U.S.A., Chemist.
1903. Wolf, Jacques, c/o Jacques Wolf and Co., Passaic, N.J., U.S.A., Manufacturing Chemist.
1916. Wolfe, Harold M., The University, Leeds. Journals to "Cliff Lawn," Cliff Road, Leeds. Explosives Inspector.
1912. Wolff, Dr. Salamon, 2, Curzon Avenue, Victoria Park, Manchester, Chemical Engineer.
1911. Wollaston, T. Roland, Dirleton House, Priory Road Sale, Cheshire, Consulting Engineer.
1903. Wolton, Wm. R., c/o Joseph Fison and Co., Ltd., Ipswich, Manager.
1914. Wood, Arthur S., 6, Walton Road, Sidecup, Kent, Works Chemist.
1916. Wood, A. Selhy, Dalehead, Stocksfield-on-Tyne, Paint, Colour, and Varnish Manufacturer.
1906. Wood, E. Esecott, Hurricane House, Brymbo, near Wrexham, North Wales, Chemist and Metallurgist.
1900. Wood, Frank, Ardsley House, near Barnsley, Yorks, Assistant Manager (Glass Works).
1901. Wood, Frank S., 12, Carlton Avenue, Hornsea, East Yorks, Cement Works Chemist.
1917. Wood, Henry, The Limes, 62, Culverden Road, Balham, London, S.W., Scientific Chemist.
1909. Wood, Hubert R., c/o Fenner, Alder and Co., Fenner's Wharf, Millwall, E., Works Chemist.
1887. Wood, Jos. T., 62, Park Road, Nottingham, Tanner.
1916. Wood, T. T., 26, Graver Lane, Newton Heath, Manchester, Technical Chemist.
1915. Wood, William, Royal Gunpowder Factory, Weltham Cross, Essex, Chemical Manufacturer.
- O.M. Woodcock, R. C., 30, Dover Road, South Wansted, Essex, Chemist.
1910. Woodhead, Arthur E., Bemerside, Cornwall Road, Harrogate, Yorks, Research Chemist.
1884. Woodhead, Jas., Inglewood, Slaithwaite, near Huddersfield, Tar Distiller.
1917. Woodhouse, William, 6, Longfield Lane, Ikeston, Derbyshire, Iron Works Chemist.
1915. Woodmansey, A., 12, Ridgeway Terrace, Dolphin Lane, Leeds, Analyst and Chemical Engineer.
1915. Wood-Mason, Harold, H.M. Factory, Queen's Ferry, Chester, Chemist.
1914. Woodroffe, David, c/o P. E. Fisher, Leather Manufacturer, Basingstoke, Research Assistant.
1900. Woodrow, John, 84, Harpenden Road, Manor Park, E., Chemist.
1906. Woodward, Horace A., Cowell Avenue, West Orange, N.J., U.S.A., Chemist.
1904. Woolecott, Geo. H., Lady's Well Brewery, Cork Ireland, Brewer's Chemist.
- O.M. Woolley, G. S., Victoria Bridge, Manchester, Pharmaceutical Chemist.
1905. Woore, N. Lycester, c/o South Australian Gas Co., Brompton, Adelaide, South Australia, Works Chemist.
1909. Work, Charles O., 22, Cambridge Road, Great Crosby, Liverpool, Chemist.
1914. Worley, Prof. Fred. P., University College, Auckland, New Zealand, Prof. of Chemistry.
- O.M. Worrall, H., Culmington House, Stanton Lacey, Ludlow, Dyer.
1903. Worstall, Roht. A., 2500, West Railroad Avenue, Evanston, Ill., U.S.A., Paint and Varnish Specialist.
1900. Worthington, Arthur, Lynwood, Great Lever, Bolton, Chemist and Manager.
1896. Wrampelmeier, T. J., 565, Monadnock Building, San Francisco, Cal., U.S.A., Chemist.
1914. Wray, Edward, 65, Manchester Road, Fairfield, near Manchester, Chemist.
- O.M. Wray, O. J. P., Hazlemere, 95, Coleraine Road, Blackheath, S.E., Technical Chemist.
1904. Wright, Allister M., Box 617, G.P.O., Christchurch, N.Z., Chemist (Christchurch Meat Co.).
1912. Wright, Arthur, 45, Markwood Road, Forest Hills, Long Island, N.Y., U.S.A., Lawyer.
1895. Wright, Arthur C., c/o Turner, Morrison, and Co., 6, Lyons Range, Calcutta, India, Chemist.
1908. Wright, C. Harold, Dept. of Agriculture, Suva, Fiji, Agricultural Chemist.

1915. Wright, E. W., 51, Bertram Road, Hendon, N.W., Analytical Chemist.
1901. Wright, Harold E., c/o Sir B. Samuelson and Co., Ltd., Middlesbrough, Chemist.
1907. Wright, John Henry, 16, Norwood Avenue, Shipley, Yorks. Technical Chemist.
1885. Wright, Jos., 19, Arboretum Street, Nottingham, Lace Dresser.
- O.M. Wright, L. T., Junior Constitutional Club, Piccadilly, London, W., Chemical Engineer.
1911. Wright, W. Robt., c/o Thos. Adams, Ltd., Sherwood Hill Works, Nottingham, Bleacher and Dyer.
1900. Wright, Walter J., 48, The Mall, Faversham, Kent, Chief Chemist (Cotton Powder Co.).
1907. Würster, Oscar H., c/o Louisville Soap Co., Louisville, Ky., U.S.A., Soap Works Chemist.
1905. Wyer, Malcolm G., The Library, State University Iowa City, Iowa, U.S.A., Librarian.
- O.M. Wyld, Jno., Rose Ville, Menston, via Leeds, Chemical Works Manager.
1908. Wyler, Dr. Max, c/o Levinstein, Ltd., Blackley, Manchester, Manufacturing Chemist.
1906. Wynne, Prof. W. Palmer, F.R.S., The University, Sheffield, and (Journals) 17, Tiptonville Road, Sheffield, Professor of Chemistry.
- Y
1901. Yardley, Frank, c/o Henry Jutson and Sons, Liverpool Street, Birmingham, Chemical Manufacturer.
1897. Yates, W. H., Durdley Park, Keynsham, Bristol, Technical Chemist.
1915. Yeoman, Ernest W., 1, Regent Square, London, W.C., Analyst and Metallurgist.
1913. Yeomans, Wm. W., c/o Standard Chemical Iron and Lumber Co., St. Henri, Montreal, Canada, Chemist.
1906. Yerkes, Leonard A., c/o Jos. Bancroft and Sons Co., Wilmington, Del., U.S.A., Bleacher and Finisher.
1898. Yetton, Thos., 86, Bow Road, London, E., Consulting Distiller's Chemist.
1894. Yocum, Dr. Jno. H., 325, Academy Street, Newark, N.J., U.S.A., Chemist.
1886. Yoshida, Prof. H., Imperial University of Kyoto, Kyoto, Japan, Professor of Chemistry.
1900. Yoshitake, E., Nishihara Machi, Koishikawa, Tokyo, Japan, Chemist.
1885. Young, Alfred C., 17, Vicar's Hill, Lewisham, S.E.
1885. Young, Brougham, Patent Hygienic Bin Co., 4 and 8, Arthur Street, King William Street, London, E.C., Analytical Chemist.
1902. Young, Chas. C., c/o The Bayer Co., 117, Hudson Street, New York City, U.S.A., Colourist.
1890. Young, Qr. Geo., Bradda Church Crescent, Church End, Finchley, N., Chemist.
1913. Young, Hamish, 21, West Park, Clifton, Bristol, Chemist.
1917. Young, Harry A., 5, Cottage Place, White Plains, N.Y., U.S.A., Chemist.
1904. Young, James, 2, Montague Terrace, Kelvinside, Glasgow, Chemist.
- O.M. Young, Jno., 2, Montague Terrace, Kelvinside, Glasgow, Technical Chemist.
1886. Young, Jno., Claremont House, Beverley Road, Hull, Gas Engineer.
1909. Young, John, 610, Weber Avenue, Akron, Ohio, U.S.A., Analytical Chemist.
1904. Young, Jno H., c/o The Cassel Cyanide Co., Ltd., Shuna Street, Maryhill, Glasgow, Technical Chemist.
1898. Young, J. W., 22, Maxwell Drive, Glasgow, S., Inspector under Alkali Acts.
1883. Young, Prof. Sydney, F.R.S., University Chemical Laboratory, Trinity College, Dublin, Professor of Chemistry.
1917. Young, Thomas O., 14, Normanton Terrace, Newcastle-on-Tyne.
- O.M. Young, W. C., Laboratory, 24, Aldgate, London, E., Gas Examiner and Consulting Chemist.
1898. Young, W. Gathorne, Analyst's Dept., G.N.R., Doncaster, Yorks, Chief Chemist.
- Z
1899. Zabriskie, C. B., c/o Pacific Coast Borax Co., 100, William Street, New York City, U.S.A. Manager.
1897. Zacharias, Dr. P. D., Philhellinon Street 22, Athena, Greece, Industrial Chemist.
1912. Zanetti, Joaquin E., Columbia University, New York City, U.S.A., Chemist.
1906. Zaremba, Edw., 707, D. S. Morgan Building, Buffalo, N.Y., U.S.A., President (Zaremba Co.).
1906. Zlanowicz, Joseph, 24, St. James's Street, London, S.W., Chemical Engineer (Artificial Silk).
- O.M. Zimmermann, A., 3, Lloyd's Avenue, London, E.C., Chemical Agent.
1905. Zimmermann, Chas., 9 and 10, St. Mary-at-Hill, London, E.C., Chemical Merchant.
1897. Zinsser, Dr. Fred. G., Hastings-upon-Hudson, N.Y., U.S.A., Manufacturing Chemist.
1916. Zumbach, Dr. Jacques, 19, Radcliffe Road, West Bridgford, Notts, Research Chemist.
1912. Zwingenberger, Dr. Otto K., 142, State Street, Perth Amboy, N.J., U.S.A., Chemical Engineer.

List of Members on Active Service in whose cases the Application of By-law 12 has been waived.

1913. Acland, L. H. Dyke.
1903. Acton, J. Rowland.
1907. Adam, Capt. Wm. Anol.
1912. Akers, Noel Charles (Sub-Lieut.).
1913. Allmand, Dr. A. J.
1915. Ashworth, Fred.
1909. Baker, Robert Percival.
1901. Barber, Capt. René R.
1910. Bowater, John W.
1913. Bridge, Stanley W.
1910. Campbell, James Robertson.
1911. Cochrane, Capt. John Bray.
1914. Cousins, Francis, George.
1913. Deakin, Lieut. John Bertram.
1915. Dickinson, Frank Edwin.
1914. Dunn, Ralph John.
1913. Farrow, Lieut. Frederick Denny.
1914. Fell, Harry.
1896. Fox, A. Stanley.
1912. Frankenburg, Sydney.
1904. Gair, C. J. Dickenson.
1912. Gloag, Vivian Ford.

1898. Golding, Capt. Jno.
1905. Hall, A. A.
1904. Heaton, Capt. Noel.
1905. Higgins, Dr. Eric B.
1908. Hughes, William Earl.
1905. King, Frank Eustace.
1907. Kynaston, P.e. Wm. Chas. Robert.
1904. Lane, Chas. Cyril P.
1907. McConnan, Dr. James.
1908. Mason, Capt. Douglas H. Campbell.
1889. Mawdsley, W. H.
1912. Millar, Charles James.
1913. Mumford, Capt. Ernest Moore.
1912. Murdoch, Barclay B.
1914. Rodger, Lawton H.
1915. Shingler, Sydney Vernon.
1913. Slade, Dr. Roland Edgar.
1909. Spence, John.
1913. Stephenson, Guy.
1902. Stevens, Lieut. M. White.
1913. Tennant, Robert.
